We congratulate our esteemed contemporary, *The Iron Age*, on having won in the first trial of its case against the State of New York. The Labor Commissioner had informed the management that it was violating the law by employing females by night in the bindery; this appeared to be an unwarranted invasion of constitutional rights, so the publishers decided to test the law. The Court of Special Sessions decided in favor of the defendant publishers. There was no pretext that the building in which the women were at work was insecure, badly lighted, defectively ventilated, or unsanitary in any way; but by virtue of a factory law the commissioner claimed that the publishers were guilty of a misdemeanor in employing females or minors before 6 o'clock in the morning or after 9 o'clock at night. There was no issue of fact, the defendant simply pled that the law was unconstitutional, in that both the employer and employed were restricted in their rights; was this restriction within the constitutional power of the Legislature? The defendant invoked the provision of the State Constitution that says: "No person shall be deprived of life, liberty or property without due process of law." Was this factory law a health regulation in the interest of the common good, or was it it not plainly and palpably an unauthorized and unwarrantable interference with the constitutional rights of the citizen? The Court decided unanimously to this effect. The case is to be appealed, and we hope our friends will carry it to a final and successful issue.

NEXT to American capital, French capital has been the most active in seeking investment in Mexico during the past year. The proportionate increase of the French investment was greatly in excess of ours, being about 100 per cent. In less than one month after Mexico went upon a gold basis, Paris bankers had secured control of the banking situation of the country by acquiring a predominating interest in the leading banks of the City of Mexico, namely, the Bank of London & Mexico, considered the bulwark of British capital in Mexico, and the Central Bank, the clearing house for all the chartered State banks of the republic. French capital has for some years held a very large interest in the National Bank of Mexico. Other French capital was invested in industrial enterprises, particularly in cotton mills and in mining undertakings.

THE ARTICLE on 'Useful Definitions' was to have appeared last week and we commented upon it at that time. However, the sound advice given by Mr. S. F. Emmons needs no recommendation, and our remarks in anticipation of the publication of the article were made in order to emphasize the fact that the hints he gives to the writers of the Geological Survey are applicable to those who perform the technical work of the mining engineer and metallurgist.

Special Correspondence.

Johannesburg, Transvaal.

Record Output for July.—The Cason Mine Comes to the Front.—Use of the Blaisdell Excavator.—Kaffirs and Coolies.—The New Constitution for the Transvaal.—Boom Days are Over.

The splendid record output for July has brightened things up a bit, even the market. The total output for the Transvaal has been declared at 491,793 oz., valued at £2,089,004. If all goes well it is quite possible that the August output will reach 500,000 oz. The increase of the July output over June is 15,818 oz. During July there were 7,705 stamps at work on the Rand, and 8,070 in the Transvaal. The most remarkable showing for the month is that of the Cason mine, one of the East Rand Proprietary group, which made its second declaration of 15,830 oz., an increase of 2,700 oz. on June. The Cason is now the third largest producer in the Transvaal. It is to be hoped that these excellent results will continue, and that the mine is not going through a 'show' period. A profit of £29,155 was declared for July. The New Modderfontein ran an additional 30 stamps during July. At this mine the Blaisdell excavator is used for emptying the cyanide vats, with good results. Should the scarcity of labor continue, it is probable that this contrivance will be introduced in several mills. Development is being pushed at the New Modderfontein, and during the last four months there were four tons developed for every ton milled. The three leading producers for July were Simmer & Jack (21,109 oz. output), Robinson (20,553 oz.), and Cason (15,830 ounces).

A number of new ventures were registered during July, principally diamond and 'base metal' syndicates. The promoters of most of the syndicates seem to be over optimistic about their ventures, especially those of the base metals. It would have to be rather a remarkable base-metal deposit to pay in the Transvaal under present conditions. There was one gold proposition registered during the month, namely the New Dupreeze Syndicate.

According to the *Rand Daily Mail*, there was a slight decrease in Kaffirs at work, about 562, and the total number now employed is 76,995. A second recruiting agency has been started, and we shall see if their boast that 50,000 additional Kaffirs can be recruited is mere talk or not. Personally, I believe that 80,000 Kaffirs is nearly the maximum that we can get to work continuously on the Rand. As regards Chinese, there are 52,203 available for the mines, July 31, 1906. The number of applications under the new notice of Liberal Government is not yet large. In a year's time the first batch of coolies will have completed their contracts. One of the leading deep-level mines for instance, will lose all its coolies (over 2,000) in August, 1907, unless they are allowed to sign on again. If the coolies go home, this mine will be forced to close down. Many other mines will be in the same fix. It is the uncertainty of the labor supply for the future that is causing the heavy depression. The constitution that has just been granted the Transvaal by the Liberals has not cheered things up very much. The general feeling is one of relief that the constitution has at last been granted. The Boers have the best of it, as they are united, while the British are split into several parties. It is more than probable that the Boers will dictate the policy of the first responsible government. They are not in love with the Chinese, but it is to be hoped that they will see the folly of re-patriating the coolies until other laborers are provided for the mines. The elections will probably come off not later than February next.

As already stated, the record July output brightened the market up a bit, but there is no reason for a rise in prices. The future is too uncertain to warrant a boom; in fact, boom days are probably over. People in Europe know fairly well now what the mines are worth, and it is not likely that they will be bluffed again into giving two or three times the value for Rand shares.

Leadville, Colorado.

Developments on Rock Hill.—Good Ore in the Louisville.—Revival at Kokomo.—Little Johnnie Resumes.

Work at the shaft on Frank W. Owers' property has been discontinued. The shaft had reached a depth of a little more than 700 ft. and entered the granite formation. After passing through several hundred feet of wash and lime clay, the shaft cut a 7-ft. layer of schist and entered the granite without cutting the productive ore formations. The information thus afforded will go far toward determining the probabilities of ore deposits on the western slope of Rock hill.

The New Monarch is at present taking out the richest ore in its history. The high-grade ore lies near the contact of a huge porphyry dike with the blue lime. The average of the recent shipments from this property has been of a better grade than that of former years.—The Reindeer, on Rock hill, is shipping from 80 to 100 tons per day. The ore now being hoisted comes from the 600-ft. level and southeast of the shaft. Prospecting is being carried on extensively in other parts of the property.

The installation of an electric hoist has been completed on the Louisville property. This hoist was installed at the Yak tunnel level and will operate through the old shaft to hoist ore from the new orebodies located by drill-holes. While data concerning the value of the new ore-shoots have not been given out for publication, the deposits are known to be extensive and of a shipping grade.—Regular shipments will start at an early date from the Robert E. Lee. The drifts are being repaired and extended, and a considerable quantity of ore is now exported.—The A. V., on Harrison Avenue, has secured a market for manganese ore. The output of the present month will amount to 500 to 600 tons.

The Delaware group of mines is soon to be re-opened. This property comprises the Colonel Sellers and Eagle in Ten Mile district. The group contains 250 acres and will be developed through an adit driven from the face of the mountain at a point much below the old workings. It is proposed to erect an 80-ton mill to treat the product of the mine. The character of the ore is lead, zinc, and iron sulphides, with low values in gold and silver.

The latest developments at the property of Judge W. H. Harrison, located in Lackawanna gulch, are creating considerable interest among mining men of this locality. It is reported that a large body of ore of an excellent grade has been opened up in the shaft. The new mill has been completed and will be put into operation as soon as transportation facilities are secured. The ore occurs in a true fissure vein and the present workings are located at an elevation of 13,000 ft.—The manager of the Emerald reports that shipping ore has been exposed at the breast of the tunnel. This property is located in Delmonico gulch.—The shaft of the old Raven property is being completely overhauled and a new plant of machinery will be installed at once.—The Little Johnnie has again resumed operations after a week's idleness. The main shaft was repaired and shipping at the former rate of 700 tons per day has been resumed. There are 73 sets of lessees on the property in addition to the large force of over 300 men directly employed by the Ibex company.

Toronto, Canada.

Railroad Lease Is Concluded.—Gold Discovery North of Cobalt.—
The New Reduction Works.—Copper in Algoma.—Coal in Alberta.

The lease of mining rights on the right of way of the Temiskaming & Northern Ontario Railway Co., for which tenders were recently asked by the Temiskaming & Northern Ontario Railway Commission, has been granted on the same terms as the former lease cancelled by the Government, to an Ottawa syndicate composed largely of the same members as the original syndicate. The former deal aroused much criticism owing to the alteration in the advertised terms, and the substitution of a flat-rate royalty on the output for the sliding scale first proposed. When new tenders were called for, the flat rate of 25% on the value of the output was substituted. The successful bidders pay, in addition, a cash bonus of \$50,000. There was only one other tender. The members of the syndicate are J. P. Dickson, A. W. Fraser, T. A. Bement, J. G. Turriff, Edmund Seybold, and George Goodwin. The first-named three belonged to the original syndicate. It is an open question whether the flat rate or the sliding scale, according to value, is more advantageous to the operators.

A number of prospectors have been at work in the area around Present or Larder lake in unsurveyed territory about 50 miles due north of Cobalt, where gold-bearing quartz has been discovered. Parties from Toronto and Hamilton have located a large number of claims and the land has been staked out for miles back from the lake shore. The country is reached by canoes by way of Tomstown and Wendigo lake.

On the 10th inst. the corner-stone of the refining works to be erected by the Montreal Refining & Reduction Co., at Trout lake, a few miles from North Bay on the Temiskaming & Northern Ontario Railway, was laid by Frank Cochrane, Ontario Minister of Lands, Forests & Mines, in the presence of about 2,000 people. Special trains were run from Cobalt camp and Copper Cliff. The plant will handle all kinds of ore with a capacity of 500 tons per day. The total cost is estimated at \$2,000,000, and it is expected that when operated to their full capacity, 1,000 men will be employed. J. E. E. Leonard is president of the company. Mr. Cochrane, in his speech, congratulated his hearers on the fact that the lack of reduction works, which had retarded the mining industry, was being overcome, and hoped that before long Canada would not only be refining but marketing its own ore.

John Black, of Cobalt, who has a wide experience of American and Mexican mining, recently returned from an investigation of copper deposits in Algoma, about 40 miles from Sault Ste. Marie, bringing some rich samples, including one large piece of ore weighing about 100 lb. and running about 35% copper. He found surface veins from 10 to 15 ft. wide running 8 to 10% copper. The region, he says, is in a direct line—according to the lay of the land—with the copper lodes of upper Michigan, and the copper deposits may be a continuation of these veins. Several parties are examining and buying up properties; some big deals in prospects are said to have been made.

The property of the Taber (Alberta) Coal Mining Co., comprising about 11,000 acres underlaid by a 54-in. vein of valuable coal, has been taken over by the Canada West Coal & Coke Co., Ltd., of which O. A. Robertson, of St. Paul, Minn., is president, and F. E. Kenaston, Minneapolis, secretary and treasurer. The company is capitalized at \$2,000,000 and will expend several hundred thousand dollars in improvements. Charlton Dixon, of Pittsburgh, has been appointed mine manager, and D. E. Adams, late secretary and treasurer of the Taber Coal Co., will be general sales manager.

Butte, Montana.

Amalgamated Officials Express Opinions on the Copper Market.—
Conditions Healthy.—Tremendous Production of the Amalgamated Smelters.—Extent of the Mining Operations.—Work at the East Butte.—The Silver Bow No. 3 to Be Re-opened.—
Ryan to Succeed Rogers.—Butte & London Making Progress.—
North Butte Getting Plenty of Ore.

John D. Ryan, managing director for the Amalgamated Copper Co., John Gillie, general superintendent and E. P. Mathewson, general manager of the Amalgamated smelter at Anaconda, make statements indicating that the Amalgamated has not a pound of copper on hand and that the product is sold far in advance through the United Metals Selling Co., of New York. Mr. Ryan says the demand more than keeps pace with the production, and that the world's output of copper last year did not exceed that of the preceding year by more than 5%. This year will show very little more of an increase over last, while the demand for the metal has been steadily increasing. "Copper mining the world over," says Mr. Ryan, "is a solid stable industry now, and very great increases or decreases in production are not likely to be experienced. New copper districts are being developed, but the very nature of the ore deposits and the necessity for large and expensive plants for treatment make the new districts come along rather slowly. It is not possible—and never will be—for any flood of copper to be poured into the markets of the world suddenly from any source whatsoever. The copper industry is in a satisfactory condition. Prices of the metal remain very good and the demand larger than at any time in the history of the business. This is due to general prosperity all over the country. Nearly all the manufacturing countries of Europe are using more copper than ever before, and the increase in the demand in the United States has been so great as to warrant an advance in the price of the metal, and that without any indication of diminishing consumption." Mr. Gillie says the Amalgamated selling agent recently received an order from a Rome, N. Y., buyer for a million pounds of copper at 19c. per pound, and he was urged to take half that amount so that other customers could be supplied. This indicates the condition of the supply. Mr. Mathewson says there is no copper stored anywhere, and that the product has been sold in advance for the year.

During the first six months of the present year the Washoe smelter of the Amalgamated Co. produced 94,244,911 lb. copper, 31,811,735 oz. silver, and 22,567 oz. gold. The smelter of the Boston & Montana Co. (also Amalgamated), at Great Falls, produced during the same period about a third as much as the Washoe. At present the Washoe smelter is producing copper at the rate of 11½% of the total production of the world, and 22% of the total in the United States. The Washoe production last year was one-tenth of the world's production. Last year the smelter produced 165,905,144 lb. copper, 7,046,485 oz. silver, and 49,685 oz. gold. The following figures show the smelter output during four years and a half and also indicate the gradual increase of the production:

	Copper. lb.	Silver. oz.	Gold. oz.
1902 eight months	82,992,361	3,368,133	15,027
1903	109,726,120	5,190,879	31,183
1904	138,078,499	6,481,318	46,344
1905	165,905,144	7,046,485	49,685
1906 six months	94,244,911	3,811,735	22,567

During the same period the smelter paid out \$26,790,986 in operations — \$7,007,324 for labor, \$4,293,455 for coal, \$4,012,000 for coke, \$740,947 for lime rock used in smelting, \$1,316,020 for machinery, \$53,896 for lumber, and \$1,480,813 for railroad freights. The total value of the

ore treated from the Butte mines in that time was \$104,316,089, the smelter receiving its supply, an average of 8,000 tons per day, from the mines of the Anaconda, Parrot, Trenton, Washoe, Butte & Boston, North Butte, East Butte, Red Metals, and Pittsburgh & Montana companies. The smelter consumes daily 14,000 tons of material, including ore, coal, lime, and coke. About 80% of the ore shipped to the Washoe carries less than 6% copper and is sent to the concentrator. The smelter employs 2,337 men in the works and 376 in auxiliary industries; it was built at a cost of \$9,500,000.

The smelter's production in 1902 was equal to 13% of the world's supply, and in 1903 it was 8.3% of the world's production and 17% of the production in the United States. In 1904 the Washoe produced 10% of the world's production of copper, and between 18 and 19% of the total of the United States. Last year its output was 20% of the world's supply and 10½% of the production of the United States.

An important by-product of the Washoe smelter is arsenic, which is extracted from the flue-dust. In 1904, when the arsenic plant was started, 2,597 tons of flue-dust were treated. The following year there were 3,109 tons and during the first six months of the present year 2,291 tons were treated, a total for the entire period of operation of 7,997 tons. Up to the first of July of the present year 1,107,178 lb. arsenic had been recovered, of which 903,178 lb. have been shipped, the remainder being still on hand.

According to figures just made public the operations of the Amalgamated mines in Butte are on a scale just as stupendous as those of the Washoe smelter. The figures do not include the mines of the Boston & Montana Co., which are also Amalgamated. The Anaconda Co. employs 3,174 men, the Parrot 378, the Trenton 232, the Washoe 326, and the Butte & Boston 438. The payroll of the Anaconda for the first six months of the present year amounted to \$1,967,489.46; Parrot, \$160,674.72; Trenton, \$55,221.45; Washoe, \$203,262.69; Butte & Boston, \$259,816.51. The total payroll of the Amalgamated Co., excluding the Boston & Montana Co., for the six months amounted to \$5,045,582.57. The same companies paid in the same time \$1,415,890.35 in local railroad freights, and \$3,000,000 for all freights, including freight on copper to the seaboard. Freight on copper amounts approximately to \$1,000,000 yearly. The same companies have in six months paid \$844,026.44 for coal, \$799,679.36 for coke, \$156,858.75 for lime rock, and \$286,533.32 for lumber.

All of the Amalgamated mines in Butte produce about 14,000 tons of ore daily. The Anaconda Co. operates the Anaconda, Never Sweat, St. Lawrence, Mountain Consolidated, High Ore, Bell, Diamond, J. I. C., Belmont, Gallatin, Sunnyside, Buffalo shaft, and some smaller properties. The Washoe Co. gets its ore supply from the Moonlight, Cambers, Paulin and Odin mines. The Butte & Boston Co. works the East and West Gray Rock, Silver Bow No. 1, Silver Bow No. 3, Berkeley and Kane No. 3 mines. The Trenton operates the Gagnon and several smaller properties, and the Parrot is confining its work to the Parrot mine.

No. 1 shaft of the East Butte Mining Co. has reached a depth of 500 ft., and No. 12—the four-compartment shaft being sunk at the southern end of the company's ground, and to be connected with No. 1—has reached a depth of 210 ft. Some cross-cutting has been done on the 400-ft. level and several veins have been opened, but no drifting will be done until the shaft is 1,000 ft. deep. Stations will be cut at the 600, 800 and 1,000-ft. levels. The East Butte lessees are mining about 150 tons of ore daily at present. In August there was a slight falling off in the

royalties paid the company owing to the fact that the concentrator was shut down for repairs. Some new machinery has been added and the plant is again treating about 100 tons of ore daily. A new concentrator of 150 tons daily capacity has been built by East Butte Co. interests and will be in operation within 30 days, when the shipment of second-class ore will be increased. About 10 acres of mineral ground lying east and west of the East Butte Co.'s ground, which was in litigation between the Amalgamated and Heinze, has been equally divided between the Boston & Montana Co. and Red Metal Co. by the Heinze settlement and each company will mine its portion of the ground. There are several rich copper veins in the ground, which have been opened by the East Butte Company.

Since the developments made by the East Butte Co., the Butte & Boston has determined to reopen its Silver Bow No. 3 mine, which lies just northeast of and adjoins the East Butte. It had been the intention of the company to dismantle No. 3 and work that property through No. 1, but the work of dismantling has been stopped.

The East Butte, which recently went into the copper precipitating business and is working over the tailing of the old Parrot smelter, is about to make its first shipment of precipitate, its tanks being full. The company has more than a mile of precipitating boxes.

A story from Boston and New York is that John D. Ryan is to succeed H. H. Rogers as president of the Amalgamated Copper Co. and that he will take the active management of the company and its affairs. Mr. Ryan, when asked about the report, would not confirm or deny it. "All that I can say is that I know nothing about it," was his answer. The report is generally believed to be true.

The Butte & London Co. is making good progress with the shaft being sunk on the Greendale claim. It has reached a depth of 615 ft., and is in very hard granite. The Butte & London has a fine surface plant, one of the best among the new companies—in fact, an extravagant expenditure has been made for surface improvements, buildings, etc. A new hoisting engine has been installed. The shaft will be put down 1,500 ft. before any cross-cutting will be done. Three of the veins in the ground of the Butte Copper Exploration Co. pass through the Greendale.

The Butte Copper Co., owning the Anselmo No. 1 and No. 2, the Robert Emmet No. 1 and No. 2, and the Trifle lode claim, has placed a new hoisting engine on the Trifle and has begun sinking the shaft, which is now down 300 ft. and will be taken to the 1,500-ft. point. New boilers, air-compressor and other machinery have also been installed.—The Davis-Daly Estates Co. is sinking on the Colorado and Silver King mines and within a week will also begin work on the Mt. Moriah. Rapid progress is being made in driving the cross-cut south from the 1,600-ft. level of the Original mine, and it is expected that within 60 days one of the big veins ought to be reached.—The Butte & Bacorn and Butte Hill Copper Co. are prosecuting development work on their properties in the new district north of the town. The Butte Hill Co. has done some driving on the copper vein opened at a depth of 200 ft., but there is nothing more there than the promise of ore deeper down.—The North Butte Co. is working at a depth of 1,700 ft. with two shifts per day. About 1,600 tons of ore are hoisted daily, the larger part of which is first-class. The orebody at that depth is from 6 to 33 ft. wide. The company will soon begin work on a cross-cut from the Jessie mine north to the Berlin, one of the claims in a group acquired by the company about a year ago.

Calumet, Michigan.

Copper Statistics for 1906.—Output of Lake Superior Region.—
Great Production From Calumet & Hecla.—Increased Capacity
of Mills.—Gossip Concerning the Cananea Central.—New
Machinery at the Hancock.—Progress at the Ahmeek.

The output of copper from the Lake Superior mines during the current year is likely to show a gain over 1905, notwithstanding several serious strikes, and the crippling of the Tamarack mine by a stubborn fire, the wrecking of the Atlantic and the closing down of the Phoenix mine.

The following table is from advance sheets of Horace T. Stevens' 'Copper Handbook,' and may be considered official, the returns, with the sole exception of the small amount of 75 tons, listed under 'miscellaneous,' being reported directly by the producers. The figures of the Calumet & Hecla vary from those previously published, for the reason that the fiscal year of the Calumet & Hecla does not end with the calendar year, in addition to which the company reports its annual output in two ways, one being the estimated copper contained in the mineral produced, while the other gives actual production of refined copper. In this case the figures are for the actual amount of fine copper produced during the calendar year 1905. The table follows, and for purposes of comparison the products of the preceding year are given also:

Mine.	(Pounds Avordupois)	
	1904.	1905.
Calumet & Hecla	80,341,019	95,100,610
Oseola	20,172,420	18,948,965
Quincy	18,343,180	18,827,557
Tamarack	14,861,885	15,821,008
Champion	12,212,954	15,707,426
Battle	12,177,729	14,384,684
Trimountain	10,211,230	10,476,462
Wolverine	9,764,455	9,464,418
Mohawk	8,149,515	9,387,614
Franklin	4,771,050	4,206,085
Atlantic	5,321,859	4,049,731
Isle Royale	2,442,905	2,973,761
Michigan	2,746,127	2,891,796
Mass	2,182,331	2,007,350
Adventure	1,380,480	1,606,208
Ahmeek	550,000	1,552,357
Centennial	641,294	1,446,584
Phoenix	1,162,201	273,219
Winnona	606,025	
Miscellaneous	50,000	150,000
Totals	208,326,218	229,270,035

Analysis of the foregoing data suggests many interesting deductions. The most important of these is the great increase in production by the Calumet & Hecla, which gained nearly 20% in output, bringing this mine, from fourth place in 1903 to first place among the copper producers of the world. The increase in output by the Calumet & Hecla is due, not mainly to smelting reserve mineral as has been erroneously stated, but rather to a largely increased rate of production, rendered possible by the great increase in milling facilities provided. The work of re-constructing the stamp-mills at Lake Linden has been under way for three years, and is nearing completion. The number of stamps in the three mills is not being increased, but the newer stamps are of greater power, and there has been a marked increase in the capacity of the dressing machinery. As the two older mills have been re-built in two sections each, 25% of the ultimate stamping capacity of the new mills, or an average of 20% of the total future capacity of all three mills, has been lacking at all times, and remains lacking with the completion of the work of re-building the fourth and final section of the two old mills, the Calumet & Hecla will be given a further increase of 20% in stamping capacity, in addition to the third section being completed during 1905. Hence it is safe to state that within a year the Calumet & Hecla will have a stamping capacity of at

least 125,000,000 lb. of fine copper yearly, and the mines are amply able to supply ore to the full capacity of the mills, hence by 1908 the Calumet & Hecla should be on a normal productive basis of ten million pounds fine copper monthly. No copper mine of the world has made as much as 100,000,000 lb. of fine copper in any year since 1902, and the Anaconda, of Montana, is the only mine that ever has made that amount in any year, production of the Anaconda having reached or exceeded that figure for seven consecutive years, from 1896 to 1902 inclusive, with a high-water mark of 131,471,127 lb. in 1897.

Thomas F. Cole, W. C. Greene and John D. Ryan have been conferring at Mr. Cole's home, in Gogebic county, on mining matters in which they are interested. It is understood that plans for the future development of the Cananea Central Mining Co.'s lands, adjoining the Greene Consolidated (in Sonora, Mexico), were discussed. The Cananea Central was organized a few weeks ago, W. C. Greene and the Greene Consolidated Co. each being heavily interested, the latter owning one-third of the entire capital stock issued. Chester A. Congdon, of Duluth, a director of the Cananea Central, says that there will be no exchange of stock by the Cananea Central for Cananea & Duluth shares, the Cananea Central Co. acquiring nearly four-fifths of the capital stock of the Cananea & Duluth outstanding from the original promoters. Reports have been current in the Lake Superior mining regions for the last few weeks that Messrs. Cole and Ryan would become identified with the management of the Greene Consolidated Co., many of these reports coming from good sources. The fact that Cole, Ryan and their associates control the Cananea Central, in which the Greene Consolidated, operating adjoining lands, is heavily interested, gives color to these rumors. It has been reported that a consolidation of the two properties was contemplated. However this may be, there is no question but that Messrs. Cole, Ryan and their associates are largely interested in the Cananea camp, and while the actual control of the Greene Consolidated is unlikely to pass to their hands, it would not be surprising if they became larger owners of Greene Consolidated shares, and were given representation in the management.

The new hoisting engine for the Hancock Con. mine, a Lake Superior property controlled by Thomas F. Cole, John D. Ryan, Captain James Hoatson and associates, has been delivered at the property. The engine will hoist from a depth of 1,500 ft. and will meet the needs of the company during the next two years, or until a larger hoist for permanent service is required. The air-compressor has been delivered by the Sullivan Machinery Co. It has a capacity to compress 1,400 cu. ft. of free air per min. and will permit the operation of 20 drills in the mine. Two 125-h.p. boilers are installed at the old Hancock shaft. Three pumps are in service in the shaft; one is a sinker, suspended in the shaft and lowered with the water; the other old one is a station-pump and the new one is a sinker. The water in the Hancock shaft has been lowered 250 ft. below the surface and it will require until November to drain all the workings. The Hancock lode is about 12 ft. wide and the old records of production show that it averaged 22 lb. refined copper per ton which is above the average of some of the dividend-paying mines of the Lake district today. The first and second level in the Hancock have already been entered, as the water is sufficiently low, but the walls are covered with slime and no examination has been made, which cannot be done without breaking down some of the rock. This will not be done until the unwatering of the shaft is completed. On surface the Hancock Con. is finishing its work on its power building. This structure will contain under one roof the compressor, hoisting engine and boilers. A

blacksmith shop is being built, also a change-house is in course of construction.

The steady increase in the working force of the Ahmeek and North Kearsarge mines necessitated the erection of additional dwelling houses there for the use of the workmen and their families. At the North Kearsarge 20 new buildings are being erected and at the Ahmeek 30 are in the course of construction. The Ahmeek is steadily increasing its production. As soon as the new surface equipment is available the mine will show an important gain in output.

London.

Dolcoath Doing Well.—Deeper Mining Encouraged,—Wheal Vor Shares Over-subscribed.—New Equipments for This Mine.—Electric Power in Cornwall.—Good Price for Tin.—The Heavy Dues to Landlords.—Decreasing Gold Output From Mysore.—Good Returns From Oroville Dredging.

At the Dolcoath general meeting the half-yearly accounts to June 30 were not only pleasing to the stockholders but appear to have given the greatest satisfaction in Cornish mining circles. The profits earned during the six months are far in excess of any figures hitherto shown in favor of the shareholders of this famous mine. The nearest approach to the present profit was in the first half of 1900, when the net gain was £32,414. This time it is £7,751 more, namely, £40,165. The following points of the accounts are of general interest:

Profit earned.....	£40,165.13.11
Tin ore crushed.....	49,334 tons
Black tin sold.....	920 tons
Produce per ton of ore.....	41.28 lb.
Average price per ton of ore.....	£1.18.11.5
Average price per ton of black tin.....	£105.13.4
Amount realized.....	£97,268. 0.9
Receipts.....	£97,910.18.0
Working costs.....	£54,502.18.9
Gross profits.....	£43,407.19.3
Lord's royalties.....	£3,242.5.4
Receipts per ton of ore raised and treated.....	£1.19.2
Working cost " " " " " ".....	£1.1.1
Lord's dues " " " " " ".....	£0.1.3
Total " " " " " ".....	£1.3.1
Company's profit " " " " " ".....	£0.16.1

In the course of his address to the meeting the manager said the shareholders would be anxious to hear something about the bottom developments more recent than the report. The 490 fathom level was now 18 fm. east of the eastern winze, and produced upwards of 100 lb. tin to the ton of stuff. The cross-course had been driven five fathoms through the lode without having yet reached the foot-wall granite. At present the lode produced 45 lb. tin to the ton of stuff; but he should be disappointed if they did not get higher values after extending the cross-cut to the foot-wall, where in the upper levels the richer ore was found. The new sump-shaft had been sunk to the 490-fm. level, and at this level the 490 had been driven 18 fm. west of the winze. The change of ground in the drift east of the new sump-shaft was distinctly encouraging and significant, inasmuch as in other parts of the mine tin had been found near similar ground. One had to think geologically both in time and extent to properly appreciate the comparatively insignificant depth which had been attained, and it struck him that the policy to be persistently pursued was the prosecution of mining still deeper.

One of the newly floated companies, Wheal Vor, Ltd., has issued a circular, stating that the 96,000 shares of 10s. each which were offered for subscription were largely over-applied for, and duly allotted, and as the promoters paid all expenses up to allotment, 80 % of the total capital of the company will be represented by cash available for work. After the capital was subscribed, an opportunity arose for the acquisition of other properties immediately

adjoining the Wheal Vor, which were of considerable value. These properties were acquired. As it is not deemed wise for the company to attempt to develop the whole of their properties, it is contemplated to sub-lease some portions. Included in the properties obtained was the Wheal Metal mine, together with the stamps and dressing floors. The acquisition of the latter will enable this company to at once begin making some returns by crushing the ore from the burrows on this and the Wheal Vor setts. Work has been pushed on as rapidly as possible on the Wheal Vor sett, and Borlase's shaft has now been cleared and put in thorough order down to the adit level. This shaft, which is vertical to a depth of 144 fm. below the adit, is 14 ft. 6 in. by 7 ft., and was found to be in excellent condition. A winding-engine and two boilers have been purchased, the former being already on the ground. The headgear has been designed, and is in course of construction. An arrangement has been made with the Duchy Development Association for the supply of electrical power, by means of which high-lift electrically-driven pumps will be worked. The rental of the installation will be extremely moderate, and when the Duchy Development Association is in a position to deliver power in bulk from a central station, the Wheal Vor Co. will be able to secure electrical energy at a lower figure than would be probable with a separate unit.

At the last reported tin-ticketing 242 tons of black tin were sold for £25,371, at an average price of £104. Dolcoath was, as usual, the biggest seller, securing £7,306 for 67 tons. Birch Tor and Vitifer, a new mine situated on the Dartmoor, received the highest price of the ticketing, namely, £118 15s. per ton, Clitters United Co. getting £115 2s. 6d. per ton for their parcel of 13 tons. While the prices obtained were highly satisfactory, it is to be noted that the total quantity sold shows no increase in the general output of black tin.

The question of 'lord's dues' continues to excite attention and comment. The custom has been traced from the early days when alluvial tin gravels existed in Cornwall, and when the tinner exercised the right to enter on any unenclosed land, mark out his 'bounds,' work the sett in his own way, and hand over one-eighth of the produce in kind to the lord of the manor. The opening of a new or old tin mine means the expenditure of thousands of pounds before any profits, or even any return at all, can be expected. Yet the landlords have hitherto exacted their pound of flesh in the shape of dues, and have charged £100 per acre for all land covered with debris or destroyed. It is said the best lease in existence in Cornwall today is at Wheal Grenville, where the dues are only out of profits and amount to one-fifth thereof. East Pool pays no dues except when there are profits, paying then one-fourth of the same. Wheal Agar, attached to East Pool, pays dues whether there are profits or losses; and during the nine years ended with 1905 is reported to have paid over £1,200 to the lord—notwithstanding that the loss on this section has been over £13,000. East Pool and Agar together, after repayment of £25,000 of calls, have divided £8,480 while paying £7,518 in lord's dues. According to the *Financial News*, it is understood that many of the recent leases have been so drawn up as to give much fairer terms. Lords apparently recognize that the ancient laws have crippled speculation, and are eager to show that they are willing to co-operate with any bona-fide capitalists.

During the month of August the output of the producing mines in Mysore, India, was 45,644 oz., showing a decrease of 450 oz., as compared with the preceding month, and a decrease of 5,156 oz. as compared with the corresponding period of 1905, while on the eight months to the end of August there is a falling off to the extent of over 30,000 oz. A decrease is also to be noted in West

African mines, the majority of which have shown a steady decline since May last; Ashanti Goldfields is the exception, the return for August being 3,609 oz., against 3,318 for July.

The quarterly dividend of 12½ cents per share just declared by Oroville Dredging, Ltd., completes the distribution of 10% for the first financial year of the company to July 31. Having regard to the substantial weekly returns which have been announced from the property for some time past, it is evident the directors have observed a conservative policy in the matter of dividends, and it is thought stockholders may look forward with some confidence to an increased distribution of profits in the near future without detriment to the sinking fund for redemption of capital as originally contemplated.

Denver, Colorado.

Politics and the Humor of Them.—Our Correspondent Says a Thing or Two.—Two Attorneys, Well-known in Mining Litigation, are Prominent.—A Dramatic Scene at the Convention.—Mining on the Williams Fork.—Reduction Works for Silverton.

Denver has just been the interested observer and host of the Democratic and Republican conventions. I say 'observer' advisedly because the people of Denver had nothing to say in either case. Each convention was controlled absolutely by the powers that be and the citizens were allowed to stand outside and get what amusement they could out of watching the bosses name their future public servants. And the people certainly got their money's worth so far as the Democrats were concerned. Of course, we always knew that the honey-mouthed politician went around before election telling the people how valiant he was going to be in defending their rights against the encroachments of the powerful and tyrannical corporations, and then after the election we knew that the same politician would probably enter a mad race for the 'retainers' of these same tyrannical corporations. We knew all this, but it was very entertaining to hear the leaders of the State Democracy give facts and figures relative to particular deals in which these particular defenders of the people had participated. The trouble all arose because Mayor Speer and Senator Patterson could not agree before-hand as to how the watermelon was to be cut. Mr. Patterson does not want to be senator again, so he says, but he thinks all other powerful candidates should be safely chained up so that when the time comes there will be no one else for the job and he will be simply forced to take it. Mayor Speer thinks he has been a pretty good mayor, as he has, and thinks he could comfortably fill a governor's or senator's chair. The net result of these innumerable thoughts was that two delegations presented themselves to the convention for recognition. Mayor Speer had C. J. Hughes, Jr., Charles Thomas, and other prominent old-time Democrats with him, and Senator Patterson had just himself and some satellites. The convention was committed by general agreement to a rabid anti-corporation platform, so it behooved each side of the controversy to show what rank corporationists the members of the other side were and how pure and valiant in the interests of the people their own members were. Never before has Denver been treated to such an insight to the secret counsels of political leaders. (Perhaps I ought to say Democratic leaders, but I don't believe in heaping all the blame on the fellow whose dinner bucket broke open and exposed the 'high-grade' inside. The other fellow's dinner bucket may conceal just as much stolen ore if we could open it). It would have taken an investigation committee and a prosecutor Hughes (of New York) six months of hard work to expose all the rottenness that was revealed in

four short hours of oratorical bombardment between these giants of Democracy. While the disclosures made were revolting, the oratory was such as is seldom heard. Hughes and Patterson excelled themselves. Both spoke from a breast full of bottled-up feelings. Hughes' best weapon is his searching sarcasm and never before has he wielded that keen-edged weapon with greater precision or more merciless effect. Patterson is forceful and logical and has a wonderful faculty for putting a bad case in a good light. It was this gift that made him a great criminal lawyer. He needed all his talents to hold together his followers, but he has it, and won out. Patterson, it should be said, has been at the head of the Democratic machine for several years. He had personally selected two-thirds of the delegates, so, of course, he was talking to a sympathetic audience, while the Speer people were talking to antagonists. In view of this fact the speech of Charles S. Thomas, former governor of the State, was one of the most brilliant pieces of oratory ever heard in Denver. If shrewd old Patterson had not so arranged it that he himself had the closing speech, Thomas would have stampeded the convention. His English was as perfect as though the speech had been carefully written, his logic was convincing and forceful, his presentation of the crimes of his adversaries filled his hearers with contempt for such rascals and he finally wound up with as pretty a play on the emotions as was ever enacted by a politician. On the Patterson side of the house sat ex-Sheriff Jones, who, as the hireling of the Tramway company, had been in a gun-fight at one of the disgraceful city elections of a few years back. Thomas had placed in his delegation an innocent man who lost a leg as a result of the above-mentioned gun-fight. As a climax to his wonderful speech he contrasted these two men. The one, a wicked hireling of the corporations, who in his zeal to serve his masters, hesitated not at bloodshed. The other, a pure and undefiled Democrat who was simply bent on exercising his right as an American citizen to vote for his chosen candidates, and in so doing was maimed for life. The incident was most dramatic. The convention was inflamed almost beyond control. But for Thomas himself, who held the vast throng, as it were, in the hollow of his hand, ex-Sheriff Jones would have been torn limb from limb and Patterson and all his delegation kicked into the street. It was a shame that the necessity of saving a human life, and such a worthless one at that, should defeat such a splendid effort. Thomas waved back the mad crowd that was rushing at Jones, and made them take their seats and—the spell was broken. Then Patterson arose and quietly but sternly drove his excited cattle back into the corral again and put up the bars. The vote was 531 to 163 against the Speer delegation, and Patterson named the candidates and wrote the platform and saw to it that Adams, the leading Democratic candidate for senator, was securely bound by pledge and platform to the nomination for Governor.

In a mining way there is not much news. Good strikes continue to be made in Cripple Creek, Clear Creek county, Gilpin county, and the San Juan. Perhaps the most important news of the week is that which comes over the range from the Williams Fork country, which is the southern part of Middle Park and tributary to the Moffat road. The ranchmen's window-sills were full of zinc, lead, and copper specimens twelve years ago when I rode through that country, but only just lately has anything commercially important been developed. The Bobtail, Luella, and Hagarstown properties in La Plata district have all struck ore, and the Bobtail is reported to have a narrow streak, in addition to four feet of low-grade stuff, that runs \$600 per ton. The principal ores thus far discovered are zinc and lead.

The San Juan Smelting & Refining Co., of Silverton, announce that they are going to put up a reduction plant of 300 tons daily capacity to handle the ores of the old Henrietta mine.

Salt Lake, Utah.

Increase of Miners' Wages.—Transfer of Alta-Quincy.—The Daly-Judge to Resume Dividends.—Weekly Returns From Tintic and Park City.—Increased Business of Local Stock Exchange.—News From Cactus and Sevier Properties.

The management of the Horn Silver Mining Co. has granted employees an advance in wages of 25 cents per day. Miners receive \$2.75 now. Tintic mine operators recently increased wages of hand miners to \$3 per day, just what machine men have been getting. The latter have made a request for an advance to \$3.25, which is being considered.

Petitions have been filed in the District Court for the voluntary disincorporation of the Red Wing Gold Mining Co., Minnie Gold Mining & Milling Co., Highland Boy Con. Mining Co., Pedro Mining Co., and the York Mining Co. All are Bingham concerns, which have been absorbed by stronger corporations.

The management of the Uncle Sam Con., following the practice of several other Tintic companies, has let out several blocks of ground to lessees. The Yankee Con. has its new compressor in operation and is preparing to undertake some extensive exploratory work. Contracts have been let for driving on the 200 and 500-ft. levels, and another may be let to sink the shaft deeper.

Shareholders of the Alta-Quincy Mining Co., at Alta, have ratified the action of the directors in consummating a sale of their mine to Tony Jacobson and associates, of Salt Lake, who will undertake a vigorous campaign of development. The purchasers are said to be negotiating for the Albion mine adjoining, with a view to effecting a consolidation. A control of the South Columbus mine has also been acquired and it may be included in the merger.

The Daly-Judge mine, of Park City, will be on a dividend basis in January next. The directors have decided to make quarterly distributions, the amount to be determined later. John J. Daly, the president of the company, has made the statement, however, that the basis will be not less than 30 cents per share, or \$360,000 annually. The company had a bonded indebtedness, in January last, of \$209,000 and an overdraft of \$22,000, which has been liquidated and the treasury now contains about \$150,000. The net earnings have been approximately \$45,000 monthly since the beginning of the year.—The management of the Nelson Queen Mining Co., operating at Park City, is preparing to install some new hoisting equipment.—The Intermountain Exploration Co., a new corporation, has taken over the No-You-Don't mine, at Stockton.

Ore shipments from the Tintic district to Salt Lake smelters last week amounted to 108 carloads, the shipping mines and respective amounts being: Centennial Eureka, 25; Eagle & Blue Bell, 6; Eureka Hill, 13; May Day, 4; Yankee Con., 5; Beck Tunnel, 5; South Swansea, 1; Uncle Sam Con., 3; Bullion Beck, 5; Gemini, 11; Scranton, 4; Dragon Iron, 5; Swansea, 1; Victoria, 3; Grand Central, 3; Mammoth, 2; Carissa, 5; Ajax, 3; Star Con., 1; Godiva, 2; other mines, 3.—The output reported from Park City mines last week amounted to 2,310 tons, the shippers and respective amounts being: Daly Judge, 819 tons; Silver King, 600; Daly West, 460; Little Bell, 174; Ontario, 206; Kearns-Keith, 51. Last week's settlement for ore and bullion in Salt Lake amounted to \$383,800 and during the same period the sales of the Salt Lake Stock and Mining Ex-

change totals 518,520 shares, representing a valuation of \$249,515, as against 130,524 shares for \$29,093 during the corresponding period a year ago.

Cripple Creek, Colorado.

Troubles of the Pharmacist Co.—Activity on Beacon Hill.—Home Run Is Prosperous—Rich Strike in the Vindicator.—Discovery in the Minnehaha.—Another Cyanide Mill to be Started.

The annual meeting of the Pharmacist Co. is to be held on September 24, when lively proceedings are anticipated. James F. Burns and the minority stockholders will endeavor to oust the president of the company, Walter F. Rock. A circular letter has been sent to all stockholders by Burns in which several complaints are set forth against the management of the company's affairs by Rock. The abolishment of the practice of paying a salary to the president and general manager is also desired. Reply to the charges has been made by Rock also, in a letter to stockholders, in which he claims that looking after the interests of the company has caused him a good deal of expense, and he at the same time accuses Burns of creating discord among the stockholders. The outcome of this meeting is looked forward to with interest.—A car of ore has recently been shipped by Gagner, McDonald and Simonton leasing on the old Gold property, on Beacon hill. The ore is being broken from the winze on a 385-ft. level and is expected to give returns of \$60 in gold. Another property on Beacon hill, the Gold Dollar, shipped a car of \$30 ore on the 14th inst. from the Murray & Ragland lease.

A new shaft is now being sunk on the Mabel M. claim of the Gold Dollar to a depth of 600 ft., which is approximately the water-level of that part of the district; a cross-cut will then be driven to cut an orebody found above in the Zoe claim.—Another clean-up has been made at the Home Run Mining & Milling Co., a gold brick valued at \$2,000 being obtained.—The Jerry Johnson Mining Co. held its annual meeting at Cheyenne on the 11th inst., no change taking place in the board of directors for the ensuing year. The board consists of F. M. Woods, Chas. Potter, J. W. Graham, Sr., and A. F. McKay. James F. Burns, who holds 22,000 shares, tried to secure a disapproval of the treasurer's report and the election of the board of trustees, but failed. He also asked to have the books of the company audited, but this request was also voted down.—A big strike is reported to have been made, by Hatcher & Seely, on the Hull City claim of the Vindicator Gold Mining Co. A tale seam of fair width is being gouged out with picks and sacked, assays as high as 45 oz. having been obtained. Two cars of \$50 ore have this week been shipped from the recent strike on the 500-foot level of the Aileen property, on Guyot hill. This property is being worked by the Colorado State Investment Co., of which John Sharpe is general manager.

A big strike is reported to have been made on the 450-ft. level of the Minnehaha claim of the Jennie Sample Co., on Raven hill. The shaft has lately been sunk to this depth and the ore was encountered in a cross-cut 40 ft. west of the shaft; it is 4 ft. wide and is thought to be the Ophir vein. This vein has lately been in dispute between the Ophir and Jennie Sample Co., the latter company having brought suit against the Ophir for ore valued at \$200,000, said to have been wrongfully extracted by them.—Cavanaugh & Co. have obtained a lease on the Wild Horse mill, on Bull hill, of the United Gold Mines Co., and will shortly start operations, the mill having been idle for about a year. The ore will principally be obtained from a 40-ft. dike on the 900-ft. level of the Wild Horse mine on which Cavanaugh & Co. have also obtained a lease. Cyanidation will be used.

Mining Summary.

ALASKA.

Jules Marion, superintendent of the Northern Commercial mail service, states that during the coming winter there will be a weekly service over the route between Nome and Dawson. This service is to be given the year round whether ice is running or not. Between Circle and Fairbanks there will be a service each way every two weeks during the winter. Between Eagle and Circle, horses will be used. On the main river below Circle dogs will be tried, as that stretch is too rough and too heavily drifted for horses.—A shipment of gold amounting to \$30,000 has been received in Seattle from the discovery claims on Eureka creek, 150 miles southwest of Fairbanks and 30 miles north of Mt. McKinley. It is nearly all in large nuggets. One piece weighs 43 oz. J. Dalton, the owner, stated that the country was rich, but that there were few prospectors in there at present. Last summer 23 men were employed on the discovery claims.

ARIZONA.

COCONINO COUNTY.

(Special Correspondence).—The Rowe claims, recently discovered, are situated less than one-half mile from Bass' Station, on the Grand Canyon branch of the Santa Fe railroad, and the Highland Mary, upon which the high-grade ore is found, joins their right-of-way. The sedimentary formations are very thick throughout the entire canyon region, and heretofore only secondary forms of copper ore have been taken out, except in a few instances, along the fault line upon which these claims lie. For the most part the ore-bodies lie flat and are cheaply mined, being near the surface. The ore is copper carbonate, with an excess of iron. On the Highland Mary, several fractures in the formation have recently been uncovered, and while the displacement has only amounted to a few feet at any place, it seems probable that the pyritic, or original form of the copper, on this claim came from great depth. A vein of quartz containing copper, gold, and silver, with considerable lead, is exposed in various places for several miles in the granitic basement of the Grand Canyon, and as Rowe has found the same ore and also quartz in some of these openings, it is thought that development will reveal large bodies at no great depth. The assays show gold and silver in payable amount, and within the past few days the copper has increased greatly. He will ship a car to the Humboldt smelter within a week or ten days.

Bass' Station, September 15.

GRAHAM COUNTY.

(Special Correspondence).—A short time ago while cross-cutting on the second level of the Longfellow mine, of the Arizona Copper Co., to connect with the new shaft being sunk near No. 5 concentrator, another vein was encountered, which assays 3% copper for a width of 40 ft. Since this discovery was made, another cross-cut has been driven 300 ft. farther east, and the old 50-ft. vein has been encountered. At the Yavapai mine, a drift has been started 26 ft. below the second level to connect with the second level of the Humboldt. Development work at the Clay mine is being carried on by means of electric drills. In order to test the extent of stoping ground above the main adit-level, several raises were put in from 15 to 90 ft., but without exposing ore good enough to stope for more than 30 ft., and the highest known point where stoping will be profitable is near the shaft, where the ore goes up 80 ft.—The tramway of the New England Copper Co. has just been completed, and ore is now shipped to the Shannon Copper Co.'s smelter at Clifton, to the amount of 40 tons per day, which will be increased shortly. Since the election of a new board of directors of this company, its affairs seem to be taking on new life. The new directors are: E. R. Morse, Boston; Eugene Wambaugh, Harvard University; Alfred R. Hoyt, New York City; Rudolph Deme, Paris, France; Edmond Bristol, Toronto, Canada.—The Burro Mountain Copper Co. is shipping 600 tons of concentrate per month to the Shannon smelter at Clifton.

Morenci, September 15.

The Cuprite Copper Co. will put in a diamond-drill, with which to prospect its properties near Metcalf. The management has concluded that it will be economy to first ascertain the position of the orebodies, after which the main shafts will be sunk.

PINAL COUNTY.

(Special Correspondence).—The Calumet & Arizona Mining Co. has purchased from J. Scanlan and E. A. Clark their group of copper claims situated in Bunker Hill mining district, on Copper creek, in this county. The consideration has not been made public, but is understood to be large. By this purchase it has secured what is believed by many to be the best copper proposition lying idle in Arizona today. The mine will be opened up on a broad basis.—The Michigan-Arizona Mining Co. is pushing operations on its property, which joins the claims of the Calumet & Arizona, and is making preparations to begin shipping ore. The orebody is being blocked out from the 50-ft. level to the 200. This ore-shoot is 90 ft. long, 50 ft. wide, and carries gold and silver besides a good percentage of copper. Other workings are being pushed to another and much larger orebody and it is expected that this will be tapped within the next 50 feet.

Mammoth, September 8.

YAVAPAI COUNTY.

(Special Correspondence).—A large body of shipping ore has just been discovered in the Swiss Girl claim, one of the Bouman Copper Co.'s group, near Jerome. The body of ore was encountered about a week ago, when a cross-cut was started from the 960-ft. level of the shaft and the second round of machine-drill holes had been blasted. The cross-cut has already been driven a distance of 20 ft. without encountering a wall. The body of sulphide ore has been found to carry gold, silver and copper enough to make it profitable to treat it at the works of the Arizona Smelting Co., at Humboldt, where it is proposed to ship the product. A body of ore, similar in character, was found in the 500-ft. level, but the value of the ore at this depth was found to be too low for profit. The company has under consideration the construction of a narrow-gauge railroad from the Swiss Girl mine to the Humboldt smelter.

Jerome, September 15.

John S. Jones is preparing to resume work on the Little Jessie group in Chaparral district. The shaft will be sunk to a depth of 1,000 ft.—Engineers are to examine the property of the Eureka Gold & Copper Mining Co. near Jerome to outline future development. The outcrop on this property ran as high as \$150 per ton gold, and at depth, where copper was encountered, the gold content was in places from \$75 to \$100 per ton, with as high as 30 oz. silver, and from six to 32% copper.—At the Mt. Union mine, 15 miles southeast of Prescott, a cross-cut on the 600-ft. level cut through four feet of ore which assays from \$20 to \$200 gold per ton.

CALIFORNIA.

CALAVERAS COUNTY.

The Union Copper Co., at Copperopolis, has decided to construct a branch railroad from its mines at Copperopolis to connect with the Southern Pacific railroad at Milton. The survey of the branch road is completed and grading gangs are now being secured. The rolling stock has been ordered and is on the way from the East. The length of the branch will be about 12 miles. Heretofore ore and supplies have been hauled in trains by traction engines. G. McM. Ross is manager.

ELDORADO COUNTY.

A new concentrator has been put in at the Sherman mill, near Placerville, to handle the increase in sulphides.—The gravel mine near Omo, belonging to Chas. Edner, has been bonded to Thos. Clark, of Placerville, who will start development work.—At the Snow mine, near Newtown, the incline has finally reached bedrock and the channel is now being opened up.—Work has been stopped at the Rosecranz mine, near Garden Valley. Near-by, the shaft on the Collins mine is being sunk, being down now 60 ft.—Superintendent Phelps of the Cedar Creek mine, near Fairplay, will start a raise to reach the channel from the end of the bedrock adit, now 1,000 ft. long.

KERN COUNTY.

(Special Correspondence).—The Tungsten mine, six miles south of Johannesburg, on the branch railroad, is working steadily shipping scheelite to Eastern markets. Some concentrating tests are in progress on this ore at the Bagdad-Chase mill at Barstow. There is said to be a large amount of concentrating ore available in the mine.

Barstow, September 10.

NEVADA COUNTY.

Preparatory to hydraulicking at the Willow Creek Con. gravel mine at Weed's Point, near Camptonville, a long bedrock tunnel is being driven to carry away the debris.—C. L. Crane plans to work the Boss quartz mine, near Sweetland, through an open-cut with a steam-shovel. After the success in working the Utah copper mines by a similar process, this innovation in gold mining will be watched with interest.

SAN BERNARDINO COUNTY.

(Special Correspondence).—The mill of the Bagdad-Chase Gold Mining Co. at Barstow is in daily operation. The gold ore from the company's mines at Camp Rochester, eight miles south of Ludlow, on the Santa Fe, is not easy of treatment, and although much of it is of very good grade, none of it shows the presence of gold except by assay or milling. The cyanide process is employed with various modifications, made necessary by the presence of copper carbonate and oxide in the ore. In the process, ammonia is employed.

Barstow, September 10.

The new copper camp at Greenwater is reached by way of Ash Meadows. Several properties on the copper belt are being actively developed and plans are being made to test others. One shaft, that on the Clark property, is down 260 ft. There is but one frame building in the camp, but lumber is being hauled in as fast as possible. The lodging houses, restaurants and saloons are in tents. Plenty of water for domestic purposes can be had at \$1.50 per barrel. The water supply is at the Furnace Creek ranch, 18 miles away, but a contract has been let by the Greenwater and Death Valley company for sinking several wells on the wash just below the Kunze camp. The district needs more teams for freighting purposes, more miners, and more carpenters. Miners are paid \$4.50 per day and carpenters \$8 per day. Johnnie is the closest railroad centre and \$50 per ton is paid for freighting from Johnnie into Greenwater, a distance of 50 miles. The Tonopah Lumber Co. is sending 20 teams to Greenwater to haul lumber into the new district, but three times as many more teams could find steady employment at freighting. An automobile service will be started from Johnnie. A fare of \$25 will be made for the one-way trip. At present the stage company charges \$18 for the journey.

SHASTA COUNTY.

Fifteen men at the Afterthought mine at Ingot were given their time by the superintendent, S. E. Bretherton. The mine was temporarily short of muckers, and the foreman, instead of laying off the machine-men and causing them to lose their time from the shift of work, told them they could go right along, but instead of on the machine-drills it would be to clean up the muck for themselves and they would be paid at the regular rate for machine-men, although the rate for muckers was 50c. per day lower. The men, however, declared that they were machine-men, and before they would demean themselves with the labor of common muckers they would quit. Consequently, they were discharged immediately.

SIERRA COUNTY.

The Empire mine, at Gold Valley, has now been developed to a depth of 600 ft. A large amount of free-milling gold ore is in sight and several thousand tons are broken down in the mine ready for the mill, which has 25 stamps. There is also a chlorination plant at the mill. The property is lighted by electricity generated by the company's water-power plant.—Extensive improvements are also being made at the Empire Gold Mines, Limited, at Gold Valley. Fifteen stamps will be added to the mill, also several concentrators. Two new pay-shoots were recently found on this property, one in the valley below the mill, and another over the hill from the present development.—A good

strike was recently made at the Antlers quartz mine 200 ft. below the croppings. It is richer than at the outcrop and larger. The Antlers mine is situated on the south side of Craycroft ridge, about one and one-half miles northeast of the Gold Bluff mine. In June last, H. W. Turner, of Portland, Ore., purchased one-third interest in the mine. The Antlers vein is different from other veins here, as it is decomposed and requires but little drilling or blasting. Work on the Antlers has been temporarily suspended until the arrival of Mr. Turner, who is in Alaska. In the meantime, however, Winrod and Deal will do assessment work on the Lost Pearl quartz mine, situated a short distance from the above-named property.

TRINITY COUNTY.

The Heslewood Mining Co., two miles east of Hayfork, has almost finished its eight-mile ditch. Men are now constructing flumes, mine buildings, and an elevator to handle the tailings. The mine will be running as soon as the water comes.—The Layman mine, near Hayfork, has been bonded for \$25,000 by Humboldt county capitalists, who have begun development work.—The McCampbell mine has closed a profitable season's run, working 12 men and two giants.—The Bonanza King mine, near Trinity Center, Joseph Porter superintendent, is preparing to add 20 stamps to the 40-stamp mill under construction.

TUOLUMNE COUNTY.

Work at the Pennsylvania shaft of the Soulsby mine, at Soulsbyville, is still under way. A new bob is being placed at the 400-ft. level. When this is completed and the new pump at the 600-ft. station is in, the Pennsylvania shaft will have a pumping plant capable of handling all the water likely to be encountered in that end of the mine. The 15-stamp mill is being repaired. At the Davidson shaft the work of unwatering the old workings is still in progress.—Will Martin, who has been working on the buildings at the Soulsby, has taken a position at Middle Camp.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—James Cousins, of Idaho Springs, has been appointed superintendent of the Doric mine by the X-Ray Gold Mines Co., succeeding John Larson. The company may shortly build a mill.—Work has been commenced by the Hendrie & Bolthoff Manufacturing Co., of Denver, on the foundations of the mills for the Griffith Mines Co., and the Democrat Mountain Mining Co. Each mill will have a daily capacity of 50 tons. The completion of these mills will permit an increase in the ore production of the camp as there are large bodies of low-grade lead and zinc ore ready for stoping in the mines, which have been lying idle for many years.—The Argentine Central railway has been extended to the Vidler tunnel of the Transcontinental Tunnel & Mining Co. The Vidler tunnel was driven 180 ft. last month and is now in 1,560 ft. on the eastern side of the range. On the western side about 100 ft. have been driven. The pipe-line, for compressed air, over Argentine pass, is nearly completed, and when finished machine-drills will be put in on the western side. Two 80-h. p. boilers have lately been set up and a large Rand Imperial type compressor is being installed, making three 80-h. p. boilers and two compressors at the tunnel. Excavating is being done preparatory to erecting a concentrating mill. A commodious boarding house has just been completed and everything is being put in shape for an uninterrupted winter campaign.

The Santiago Mining & Milling Co. is shipping 25 tons of high-grade lead ore per week from its mine in East Argentine to its mill in Georgetown where it is sampled and shipped to the Independent smelter at Salida. The company's mill is supplied with an excess of custom ore from almost every shipping mine in the district, as the company buys any ore from the lowest grade concentrating material to the highest grade smelting ore. There are five adits on the Santiago vein varying in length from 700 to 1,500 ft., all of which are connected by raises except No. 4 and 5. The orebody is continuous throughout all the adits and raises and varies in width from 1 to 6 ft. There is about 100 ft. between each adit.—The East Argentine Tunnel & Mining

Co., driving the Sidney adit into Pendleton mountain, has been making excellent headway. The adit is now in 1,500 ft. in which distance nine lodes have been cut. The company owns a fine water-power which operates the air-compressor furnishing all the power required nine months in the year at extremely low cost, during the other three months the adit is not driven. The company has a large and unexplored territory ahead of the adit.

Georgetown, September 15.

OURAY COUNTY.

There is a possibility of settling pending litigation on the Ruby Trust property at the next term of the District Court, when work will be resumed on the mine, which has been idle since the buildings were damaged by a snowslide about three years ago.—Work has been progressing satisfactorily at the Bagdad property in the Sneffels district, which is being operated by the Bagdad-Chase Mining Co. W. B. Kehoe is superintendent. The work of cross-cutting from the drift every 10 ft. is being continued, and the last few times the cross-cut has shown good ore. A contract will be let for driving 750 ft. The ore is lead-silver bearing and also contains copper. The Bagdad-Chase Co. is also operating extensively in California in San Bernardino and Tuolumne counties.

SUMMIT COUNTY.

(Special Correspondence).—The last strike made on the Wellington mine proves of greater importance than at first supposed. In a raise 150 ft. above the lower level, a drift run west 15 ft. struck a vein of zinc ore five feet wide assaying over 30% zinc. This has since opened out to eight feet.—At the Wire Patch, the whole plant has been started up by the general manager, J. C. Putner. Mr. Knappie is at present in charge of operations.—At the Puzzle-Gold Dust, sinking is progressing on the main vein and the orebody is holding out strong all the way down. The electric power from the Colorado Con. plant is operating the hoist and pump satisfactorily.—A long-term lease has been taken by P. W. Breene on the Long & Derry mine, in the California district, and he expects to install adequate machinery and do vigorous development work.—The Summit-Banner Placer Co., operating in Iowa gulch, has had a successful season, under the management of Lemuel Kingsbury. The year's work has shown a good profit despite the fact that a lot of dead work had to be done. A dividend will be paid.

The old Robinson mine, at Robinson, in Ten-Mile canyon, has been leased by the International Mining Co. and new machinery is being installed. The company has also erected new buildings and is sinking a new three-compartment shaft, which is already down 100 ft. Drifting and stoping will not be commenced until the shaft is down 1,000 ft. This is giving a general impetus to the whole section and promises to revive the camp to the old-time activity prior to 1893.—In the Felicia Grace, at Kokomo, the orebody recently struck is developing satisfactorily. The management intends to sink the main shaft 225 ft. farther to reach the second contact.—The Columbine has been started up again and the main shaft is being deepened.

Breckenridge, September 8.

NEVADA.

LINCOLN COUNTY.

(Special Correspondence).—The property of the Nevada Con. mines is the scene of much activity this week, as three 15-h.p. Union hoists arrived and were placed in position at the Black Dog, Lodi, and McGhan shafts. The shafts are now down 200, 180, and 85 ft., respectively, and all will be sunk to the water-level. One shaft, that on the Lodi, will be equipped with a cage, while the others will have a skip. Cross-cuts and drifts will be run every hundred feet.—The Cyrus Noble vein is being cross-cut from the station on the 500-ft. level. The shaft is being sunk in the foot-wall, but the intervening distance at this depth is not great—less than 20 ft. The orebody continues to improve in value in the north drift. Several raises are being made, as well as chutes, so as to be prepared for extraction.

The Pacific Coast Mines Bureau has purchased the Green group, consisting of the Green, Green No. 1, Hero, and

Arabo lode claims. This group lies in the southern part of this district, and adjoins the estate of the Saturn Mining Co.—The Searchlight Mining & Milling Co. is installing two 54-in., 70-h.p. boilers. The 25 tanks comprised in the cyanide plant have been moved from the Southern Nevada mine and placed in position west of the mill building.

Preparations are being made to sink a double-compartment shaft to water-level on the Duplex Extension. At present there is a 70-ft. shaft on the Eucher claim, belonging to this company, and the new shaft will be sunk 500 ft. east of this shaft on the same vein.—Frank Miller made a strike on his property in Eldorado canyon this week. On the Minnie M. claim he has opened up three feet of oxidized quartz that runs \$106 in horn-silver and \$8 in gold. The property lies on a vein parallel to the Stoner group, now under option to Chas. Schwab.

At a depth of 100 ft. there has been an important change in the Annette shaft. What appeared to be a cross-vein has been cut and it materially affected the general character of the ore. There is more silicification and less copper-stain, also the grade is better. The shaft is being sunk on an incline of 76° and the foot-wall slip, which has been followed, still runs true. The vein will not be prospected until water-level is reached—at an estimated depth of 225 ft.—The Searchlight Western Co. is cross-cutting the vein at the 150-ft. level for a distance of 18 ft. At the 200-ft. level the vein-matter is a bluish porphyry and impregnated with sulphides. The present contract calls for a 260-ft. shaft.—The finest shaft in the Searchlight district is being put down by the Colorado Mining & Milling Co. on their Gray Ghost claim. It is double-compartment, square-set with 6 by 8's and lagged with 2 by 12's. The manway is one foot wider than the cageway in order to give ample room for pipe-columns and air-pipe. This group comprises the Gray Ghost, Baby Phil, New Year, and Anniversary mining claims.

Searchlight, September 14.

NYE COUNTY.

(Special Correspondence).—The sensation of the week is the finding of specimen ore on the property of the Manhattan Cowboy Mining Co. The strike was made on the western end of the Iron King claim on a vein just opened from the surface. Samples taken from the vein at a depth of 4 ft. assayed \$15 per ton gold. The vein proved to be six feet wide, and at a depth of seven feet the specimen ore was found. It is the supposition that this vein is the same as that of the Union No. 9 and Little Gray. The quartz is identical, and the vein can be traced in a straight line across the hill to the properties named. The Cowboy Co. has 2,000 ft. on the vein. The ore now assays \$75 per ton gold. The lessees on the Cowboy dug holes all around it, but missed the vein. J. Ness, a lessee, on No. 5 on the Iron King, sunk a 35-ft. shaft within five feet of this rich vein, and at that depth decided to cross-cut a short distance. It was done at random, and he decided to cross-cut north. Had he gone to the south, he would have had the rich vein within 10 ft. Ed Mulcoy and Jack Stinson found the new vein. Mulcoy took Lease No. 3 on the Iron King of the Cowboy Co. last February, and has been at work ever since. Stinson was put on the surface last week, and found the vein after a few days' work. Mulcoy, who was at work on the lease, told Stinson he knew about where this ledge cut through the ground, but was unable to find it. Another shift will be put on, and sinking pushed ahead rapidly.—The adit on the Georgey group on the Manhattan Nevada Gold Mines Co., at Central, is showing up fine. Ore has been exposed in the face of the adit and in the face of both drifts, which are run from the adit. The ore in each place is of milling grade, and pans well, and there is a large quantity of it.—Two shifts will be put to work on the Georgey adit, as fast as a favorable vein is encountered, and new men will be put to drift on it.—The company's engineer is now on his way to Manhattan to go thoroughly over the Copper Farm and Eldorado claims of the Manhattan Nevada Gold Mines Co., with a view to selecting a suitable place—on one of the numerous veins that have been opened on that part of the company's holdings—to sink a shaft.

Manhattan, September 15.

Personal.

POPE YEATMAN is in Alaska.
F. W. BRADLEY is at Spokane.
E. HENRY DAVIES is at Teneriffe.
OSCAR H. HERSHEY is at Nome, Alaska.
HUDSON H. NICHOLSON is at Goldfield, Nevada.
C. A. V. BOHN is now a resident at Mexico City.
EDWARD SKEWES is examining mines in British Columbia.
NORMAN C. STINES is at Carrville, Trinity county, California.
HORACE W. OGILVIE is exploiting tin mines near Nome, Alaska.
E. J. HOWARD WRIGHT is on his way from London to Bolivia.
C. W. PURINGTON has returned to Denver from Eureka, Colorado.
WILLIAM L. COBB is examining mines in Kern county, California.
RUFUS M. BAGG has returned to West Springfield, Mass., from Mexico.
CHARLES BUTTERS sails for New York from Liverpool on September 27.
STANLEY CLAY, on his return to London from Siberia, has gone to Spain.
E. C. COLLINS has left Bisbee to take charge of mines at Tonopah, Nevada.
J. S. PRYOR is in charge of the Burra Burra copper mine in South Australia.
W. L. AUSTIN has been examining the Granby mine, at Grand Forks, B. C.
GELASIO CAETANI was in San Francisco this week, on a visit from Kellogg, Idaho.
T. C. OLIVER is superintendent for the Stanley Mines Co., at Idaho Springs, Colorado.
J. W. BENNIE, manager of the Shannon Copper Co., has returned to the mine from El Paso.
FRANK J. BOOTH has accepted a position with JOHN B. FARISH at Dolores, in Sonora, Mexico.
L. S. AUSTIN, professor of metallurgy in the Michigan College of Mines, has returned to Houghton.
F. M. MILLER has resigned the superintendency of the Gaston mine, near Washington, California.
FRANK NICHOLSON has returned to Joplin, Missouri, from an extensive professional trip in the West.
JOHN ROSS, JR., consulting engineer for the Yellow Aster Mining Co., at Randsburg, Cal., is at the mine.
MARTIN J. HELLER, consulting engineer to the Nipissing mines, of Cobalt, Ontario, has returned to San Francisco.
CHAS. F. SELBY has been appointed chief chemist and superintendent for the Greene Con. Copper Co., at Cananea.
JAMES COUSINS has been appointed superintendent of the Dorie mine of the X-Ray Mining Co., at Georgetown, Colorado.
FREDERICK S. HARRIS, of Chicago, has been appointed consulting engineer for the C. O. D. mine at Goldfield, Nevada.
JOHN THIEBES has been appointed superintendent of mines for the Oaxaca Exploration Co. in the Ejutla district, Mexico.
J. M. HYDE has resigned as professor of mining at the University of Oregon to take up professional practice in Mexico.
B. J. HEATH is in charge of mine development at the Heath mines for an Eastern company, near Rochford, South Dakota.
E. E. GARDINER has been appointed superintendent of mines for the Dominion Copper Co., at Phoenix, British Columbia.
CHARLES M. BECKER, manager of the Independence

mine at Cripple Creek, has been visiting the mines of Grass Valley, California.
A. J. KLAMT has resigned as manager of the Mohawk Alpine mine at Silver Peak, Nevada, to represent Eastern interests at Rhyolite, Nevada.
FRANK ROBBINS, of Los Angeles, is at Nome, Alaska, acting in the capacity of consulting engineer for a Los Angeles company owning hydraulic property there.

Books Received.

NOTES ON METALLURGICAL MILL CONSTRUCTION. Edited by W. R. Ingalls. Published by *The Engineering and Mining Journal*. This volume of 256 pages is a reprint of articles bearing upon the most important details that enter into the construction of metallurgical plants. The articles appeared from 1902 to 1905 in the pages of our contemporary at New York and in some cases they were abstracted from the transactions of technical societies, but in their present convenient form they represent a mass of well selected and carefully edited material on an important branch of engineering practice. Among the contributors are many men who have achieved distinction in engineering work. In addition to his labor as compiler and editor of the volume, Mr. W. R. Ingalls is the author of many of the best articles, for mill construction is a subject on which he is particularly well qualified to write. The book is subdivided into seven parts, covering I, Brickwork and Concrete; II, Building Construction; III, Ore-Crushing Machinery; IV, Driers and Drying; V, Conveyors and Elevators; VI, Disposal of Tailings, and VII, Miscellaneous. The book is convenient in size and attractively bound. The price is \$2 and it is for sale by the MINING AND SCIENTIFIC PRESS.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

THE origin of petroleum oil is in doubt; some attribute it to volcanic action, others to segregation from organic matter in sedimentary rocks.

A MILL built at some distance from an unpatented mine may be considered as 'improvements' chargeable to annual assessment to the extent of \$100 to each claim of the group.

MANY 'sandstones' throughout the world are built of volcanic material—that is, are composed of volcanic detritus, which has been carried by water or wind many miles from its place of origin.

CLEAVAGE in rocks is regarded as being largely due to compression. It has been computed that in the slates of Penrhyn the absolute compression has been such as to reduce a width of 100 to one of 43, or to about one half of their original volume.

GASOLINE engines may be employed for hoisting and for other purposes, underground, but the exhaust must be conveyed out of the mine by means of an air-tight pipe, as the fumes would prove an element of great danger if allowed to escape into the mine workings.

A TEMPERATURE of -60 to -80° F. is not dangerous to human beings who are properly clothed, if the air is still, while 30 or 40° higher, if accompanied by a gale of wind, would kill every living thing before it. Very low temperatures almost invariably coincide with perfect atmospheric quiet.

WHERE a vein or ore deposit has but one well-defined wall, it is often observed that as the ore gradually thins out along the strike, the wall not infrequently continues and ore is found on the opposite side of the fissure—the hanging wall of one shoot becoming the foot-wall of the next shoot, or vice versa.

UNDER no circumstances may anyone take up a mining claim on patented land, either agricultural or mineral, without consent of the owner. Mines worked on patented agricultural ground have no extra-lateral right and cannot acquire any by locating the patented agricultural land as a mining claim.

BITUMEN is occasionally found in volcanic rocks. A California instance is the occurrence of bituminous matter in a small fissure in rhyolite in Garfield cañon, in Calico mining district, San Bernardino county. This occurrence has led some to think it might be profitable to bore for oil there. The occurrence is too superficial and small, however, to justify any such expense.

THAT quartz is opaque is due largely to the myriad cavities which it contains. These cavities may be vacant, but often they contain water and liquified carbonic acid gas. Sorby discovered the fact that they may be so microscopic in size that a thousand millions of them in a cubic inch is not unusual, and the enclosed water often constitutes one to two per cent of the volume of the quartz.

A GOOD SINKING-PUMP will raise a large amount of grit and small rock fragments with the water, but this fact should not be taken advantage of. The suction end should be protected by a good screen of heavy wire netting, which will admit water to the full capacity of the

pump, while keeping out the grit, to a great extent. Neglect to make this provision causes great and unnecessary wear on the pump valves and also upon the barrel of the pump.

EGYPT was the California of the ancient world. The kings of Assyria and Babylonia obtained their gold from the Pharaohs. A papyrus has been found describing the mines of Akita in the eastern desert, which were reached from the Nile at a point near the modern Dakka. A great mining people lived in the mountains between the Nile and the Red Sea in the days before the Ptolemies. Scarcely a trace of them survives but the gold mining industry has been revived recently by Englishmen.

IN chloridizing roasting the material (ore or matte) is roasted with common salt, the metal to be extracted being converted in the roasted material to the form of chloride. For successful chloridizing roasting it is necessary that a certain percentage of sulphide be present, that upon oxidation the sulphur may attack the sodium chloride, freeing chlorine gas, which then acts upon the metal to be extracted—usually silver, though gold, copper and other metals are also affected.

THE first vessel to navigate the great lakes was the *Griffon*, built by La Salle and his party in 1679, near the site of the present city of Buffalo, on Lake Erie. The *Griffon* was about 50 tons burden, and carried La Salle with 34 men and five guns safely from the point where she was built to Mackinac, and thence to Green Bay. She started to return with a cargo of furs in the following year, but was lost, probably on Lake Huron. From the 50-ton *Griffon* to the 7,500-ton iron ore carrier of today is a long step.

NOT infrequently, in mining in the zone intermediate between completely oxidized ore and the sulphide, pyrite or other sulphide appears in the wall-rocks before it is noticed in the vein itself, probably due to superior opportunities for the passage of surface water within the vein with consequent oxidation of the sulphide. The fact that the pyrite of the walls is relatively barren of precious metals is no indication of similar poverty of the sulphide in the vein, for it is only rarely that the pyrite of the vein walls contains more than a nominal amount of gold or silver.

COBALT, in the form of erythrite (hydrous cobalt arsenate) is found in small amount in the Kelsey silver mine in a heavy-spar gangue. This mine is in San Gabriel canyon, five miles north of the town of Azusa, in Los Angeles Co., Cal. It was worked about 14 years ago and at that time produced some very rich silver ore, much of it being native silver. Cobalt ore is also found in the Josephine mine on the Mariposa estate, owned by the Mariposa Commercial & Mining Co., three miles north of the village of Bear Valley, Mariposa Co., Cal. The mineral in the latter instance is danaite, a sulpharsenide of cobalt, and erythrite, as a result of decomposition of the former.

EL COBRE copper mines, of Santiago, Cuba, were worked by the old English and Spanish companies within an area of about 1.5 by 0.25 miles, the old workings being represented by numerous open pits and more than 40 shafts, most of which were of shallow depth only, and several, according to old records, were bottomed in good ore at the time the mining operations were suspended. Beyond these old surface-workings the gossan outcrop continues strongly for several miles easterly along the strike of the formation. The copper-bearing rock of the region is of volcanic nature, a tufa, usually highly decomposed near the surface, but often showing a brecciated or conglomeratic structure.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

About Foremen.

The Editor:

Sir—The communication by 'Miner,' in your issue of August 11 under the caption 'Too Perfect for Use,' called to mind some correspondence which passed not many years since between a large operator in the Pennsylvania coal-fields and a mining engineer of that State with whom I was at the time associated. The operator was the owner of four large mines which, from the nature of the seams, were easy to work, and being one of the 'old-school' type of men with whom rule of thumb methods (?) prevailed, had never employed a regular mining engineer to keep up mine surveys closely and to provide accurate and elaborate maps, thinking such refinements altogether too fine-spun and expensive for the prosaic business of mining coal.

But one day the inevitable happened. By reason of guess-work in the matter of locations underground a bad accident happened; besides causing a serious financial loss in the mine itself, a number of men were injured,

Experimental Cyanide Plant.

and the old gentleman was mulcted about \$10,000 in damages awarded by the courts, it being shown that the fault lay with the operator in not providing accurate maps of the working places.

It then occurred to the operator that he had better have regular surveys made and he wrote to the engineer above referred to, asking him to recommend someone for this work. He stipulated in his letter that he wanted a young man of good qualifications as a surveyor and draughtsman, one that did not use tobacco or liquors in any form, one whose language should at all times be innocent of profanity, and that when not engaged in keeping up the surveys and maps required, should be at the call of the inside superintendent for any work he might want done, and if this did not fully occupy his time, that he should assist the outside superintendent or the head book-keeper at the office. He did not state that he wanted him to teach a class in the Sunday school, lead the church choir, and take an active part in the Christian Endeavor and Wednesday evening prayer meetings, but from our knowledge of the man, it was fair to expect that it would come to this in time. For a young man possessing these qualifications he was willing to pay \$40 or \$45 per month, and he earnestly desired the engineer to secure such an assistant for him.

The engineer replied, "My dear Mr. Brown, the boys who would fill your bill are all dead, and no more are being born. Yours respectfully, Smith."

The following day, however, the engineer wrote the old gentleman a long, 'fatherly' letter advising him what he should expect of a man for the place to be filled, that he should get a man simply and solely for engineering work, not forgetting to remind the operator that he knew full well the disastrous results of incompetent or inadequate work, and advising him that he thought he could get such a man for about \$3,000 a year. It resulted in the operator's employing a man such as the engineer recommended at a salary of \$2,500, and no questions asked about the frills.

Since that time, so far as I have heard, there have never been any serious accidents at any of the four mines in question, due to imperfect mine maps.

The moral is that men about mines should be selected for their fitness for the particular work they are held responsible for, and when they fill this bill, they give value received for their wages. Any extra accomplishments they may possess in the way of tact, dignity, and social polish may be useful in advancing them to other

Another View of the Same.

positions, but the chances are that such a paragon as the one described in your extract from 'The Business of Contracting,' or as that specified by the Pennsylvania mine operator, when it comes to the real hard knocks incident to the business of 'getting there' in everyday work, will be found 'too perfect for use.'

A. B.

New York, August 30, 1906.

Tube-Milling in Korea.

The Editor:

Sir—We are at present experimenting on a practical scale with re-grinding our concentrate in a tube-mill with cyanide solution. It occurred to me some months ago that cyanide solution could be used just as well as water, when reducing our concentrate to slime, and incidentally some of the gold could be extracted while grinding. In other words, the tube-mill could be used as a grinder and agitator combined.

This company (Oriental Con. Mining Co.) has constructed an experimental plant consisting of one tube-mill (2½ by 12½ ft.), two mechanical agitators with plow shoes (8 by 6 ft. diam.), three filter and settling-boxes (4 by 5 by 5 ft.), 48 separate-compartment zinc-boxes, two sumps, and one stock-solution vat. An electric motor furnishes

the necessary power. The tube-mill was constructed in this company's shops.

The method is a continuous one; the concentrate is put into the hopper with cyanide solution and upon passing through the tube-mill is nearly all ground to slime and a good percentage of the gold is extracted. At the end of

muller is allowed to work down on the charge and agitate for a few minutes, then settled and decanted. Following this come two successive weak cyanide washes to remove cyanide and gold, and finally a water-wash which is run through a row of zinc-boxes to waste. Now the charge of about five tons of clean concentrate is ready to be discharged into the creek. A little water is added, the muller set in motion and lowered, the discharge-hole opened, and now the agitator will discharge itself readily and prepare for a new charge. The total treatment takes 24 hours, both agitation and decantation being done in the agitators.

By feeding the concentrate and cyanide solution with a consistence of one to one through the tube-mill, we are able to get the finest grinding and the best results. The agitators will only have to be filled once to contain a full charge. While one agitator is being filled, the other is decanting and getting ready to be discharged. At the head of the launder (leading from mill to agitator) a pipe was run to the stock cyanide vat above, so that we can add enough solution to keep the launder clear. With clean concentrate, it is necessary to have a steep grade.

The strong cyanide solution (0.43%) is used in the tube-mill and agitators, while the weak one—employed for washes—tests 0.1%. No cyanide is added to the weak solution. Lime is added (about two pounds per ton) with

the mill is a spitzkasten (3 in. wide by 1½ ft. long by 1½ ft. deep) supplied with clear water from the bottom. What discharges from the bottom of the spitzkasten is coarse concentrate and clear water, that passing over the spitzkasten is the cyanide solution and slime. The coarse concentrate that may escape from the tube-mill is caught in the settling-boxes and again re-ground, while the overflow contains very little value (tests 0.005 to 0.01% KCN and assays six cents per ton). We cannot arrange to run this overflow or waste-water solution through a separate line of zinc-boxes. In this small plant the value of this waste solution will not amount to more than \$2 to \$3 in 24 hours. The slime concentrate and cyanide solution pass on to an agitator which has been set in motion (13 rev. per min.) and the muller lowered. Here the product is agitated for about 15 hr., the muller is then raised two feet, the agitator stopped and the concentrate allowed to settle. It takes about one hour to settle clear; by the addition of some milk-of-lime it could be made to settle in half an hour. I prefer to use as little lime as possible because the strong alkaline solution consumes a large amount of zinc. The clear cyanide solution is decanted by a float siphon into filter-boxes and from there it is run through the zinc-boxes and the gold precipitated. Next, the strong precipitated cyanide solution from the sump is pumped up to the agitator as a wash to partly remove the gold remaining within the settled concentrate. The

the concentrate as it is fed into the mill.

The old method of cyaniding concentrate here is by mixing with 48% sand and percolating in vats from 20 to 30 days. This method gives an average extraction of 80%.

The extraction obtained at present with the tube-mill and agitators on clean concentrate is 93%. By

Tube-Mill and Experimental Cyanide Plant.

Taracol, Korea.

gradually making improvements we may possibly better these results.

A. E. DRUCKER.

Chittaballie, Korea, July 20, 1906.

A Confusion of Terms.

The Editor:

Sir—It is time that somebody was protesting against the misuse of such common appellations as 'mining man,' 'cyanide man,' and the like. Such terms are discreditable to the profession, and confusing to the layman. The scaliest of promoters, the wily stockbroker in the booming mining camp, ensconced behind his spider-web of fraud, the 'new process' man on the track of the promoter-manager, all are, without distinction, called 'mining men.' The layman usually discriminates more intelligently. He never confounds a lawyer with a doctor, a mere 'healer' with a genuine Christian Scientist! But all men who talk mines or think mines are 'mining men' to him. He does not hesitate to accost the respectable mining engineer with such jaunty greeting as "How's things looking in the new camp?" or "What's the tip on Happy Girl or Bullfrog Jim?" By the same token, the drummer assumes that every passenger he sees on the train "carries a line of goods." The time is ripe for the enlightenment of the layman. The distinctions should be clear and sharp, and I cheerfully offer the following classification to the consideration of the laity and mining public: (1) Mining engineer: the technical graduate; (2) mining engineer: the man who has won his title from experience, and if not prejudiced, may be a good man; (3) mine owners: these are often their own engineers; they make many mistakes and squander money that should be devoted to dividends; (4) mine managers: a class susceptible of about ten subdivisions, too varied and picturesque to admit of brief description; (5) promoters: men whose business it is to sell a mine and let the future take care of itself; they have usually tried other lines of work and failed, like insurance agents, and presidents of miners' unions; (6) metallurgists: who may be divided into those who have a process to dispose of, and those who dispose of processes; (7) brokers: a species of human spider, called by their friends 'mining men' to disguise their real vocation; finally (8) the 'mining man' who decorates brokers' offices and cigar stands with his imposing person, and is sometimes reduced to working for a living.

The above classification is simple and may be easily memorized.

There is another class of expert known as 'cyanide man.' The title has a wide range—from the metallurgical engineer down to the man who shovels out sandvats. The 'cyanide man's' supreme hour of triumph is when he passes from the stage of 'solution man' to engineer, and advises his company to treat all ores by the cyanide process, because it happens to be the only thing he is conversant with. Fatal mistakes due to such narrow specializing are common enough. In these days of electrically rapid changes and merging of processes, no more latitude should be allowed the 'cyanide man' than the amalgamating man, the concentrating man, or the tube-mill man. The well-equipped metallurgist should be conversant with all processes, and be able to estimate the value of each in its proper proportion. The term 'cyanide man' is destined to short life. But even if it live, why saddle upon a harmless individual a designation so horrific and one so apt to prejudice the timid layman; and why indulge in such vulgarities as 'mining man' when we may so easily designate the varieties? We do not say 'doctor man' or 'lawyer man'; and yet it is common enough to speak of the gas man, the vege-

table man, the garbage man! With the introduction of phonetic spelling, a reform in professional mining nomenclature is distinctly in order.

OBSERVER.

Denver, September 2, 1906.

Siberian Concessions.

The Editor:

Sir—Anent the subject of Siberian Concessions in your issue of August 18, it is interesting to note the inevitable complication of another concessionaire as indicated through the Imperial intimation of the gentleman at the Imperial Russian Consulate of San Francisco. As I myself was the accredited engineer of the 1900 expedition of the East Syberian Syndicate, Limited, whose work was prematurely ended by the impossible attitude of the incompetent Russian official in charge of that expedition, I have watched with much interest the affairs of the successors to the Tchouktchi concession. This concession was arbitrarily canceled and made forfeit as the result of differences that arose between the Anglo-American and Russian officials of the expedition mentioned. It occurs to me that the Imperial intimation published might fairly be seconded by other data which have been developed at the expense of the concessionaires to the territory specified, namely:

1. That in the Tchouktchi peninsula there have not been made, neither through company expeditions nor through the labor done and untold hardships endured by lessees, any discoveries of gold of any importance; on the contrary, though similar geological conditions extend from the Alaskan peninsula to the corresponding Siberian land about East Cape, the rivers, gulches and beach-sands of the Russian side have proved comparatively barren of gold.

2. That the successors to the East Siberian Syndicate, Limited, did develop some salmon fisheries to such an extent that these fisheries became the main asset of the new company; and it must be these same fisheries that were gracefully conceded by the Imperial Russian government to Japan by the terms of the memorable treaty of Portsmouth.

"In the interests of all parties concerned" it is well to give warning of the trickery that is thinly veiled in the formal communication of the consular servant of Imperial Russia.

FORBES RICKARD.

Denver, August 27.

'GUDGEONS' are the metal journals of a horizontal shaft, such as of a water-wheel. For moderate speeds we may calculate,

Diameter in inches for cast-iron = $\frac{\text{weight in pounds on the gudgeon}}{20}$

If the gudgeon is to be of wrought-iron add one-twentieth to this diameter. The pivot, or lower end of a vertical revolving shaft, should be flat, and both it and the step or socket upon which it rests, should be of hard steel. If it has to revolve rapidly and continuously, it is well to proportion its diameter so that it will not have to sustain more than 250 lb. per square inch; otherwise it will wear quickly. Dust and grit should, for the same reason, be carefully guarded against. Pivots which revolve but seldom and slowly, as those of a railroad turntable, may be trusted with half a ton or even a ton per square inch. As a general rule cast-iron pivots should be trusted with but half the load of steel ones. A steel one may be inserted partly into its cast-iron shaft, and the whole strengthened by bands shrunk on.

TRULY it has been said, that to a clear eye the smallest fact is a window through which the Infinite may be seen.

Directions for Working Rock-Drills.

The rock-drill, above other machines, is the most subjected to rough treatment, the more so underground, where, because of the bad light and want of space, and also from the inexperienced hands in which it is often placed, it gets more knocking about than is good for any machine, not constructed on the soundest model and of the strongest material.

In some kinds of rock the bit is very liable to stick, and then the workman hammers at it or upon the body of the drill with whatever first comes handy. A blow from a hammer is the quickest way to release a drill, and will do no harm to a first-class machine, but the blow should be given to the steel, and not, as often happens, on the piston rod or machine itself. To illustrate; an instance is given by Davies, who in using machine-drills in a mine in the south of France, where the miners were a hot-headed mixture of Spanish and French blood, had trouble, arising from the men, when the bit stuck, striking the front-head (stuffing-box) of the drill and often breaking it, perhaps accidentally, perhaps maliciously, since such a break would create a delay arising from the necessity of changing machines. In that particular mine it happened that the miners were much against the introduction of machine labor for stoping. In fact such was their opposition that the drills were set to work under police protection, but, notwithstanding all precautions, the first man who undertook to run one was assassinated, and the roof of the underground superintendent's house was destroyed by dynamite. This opposition arose from their idea that they would be thrown out of employment as soon as rock-drills were set to work.

It is difficult to find and train men well fitted to the work of running a drill. What is wanted is a man of an energetic, ingenious turn of mind, possessed of much patience, who will take pride in overcoming difficulties in his way, and who will not be happy until he has done so. At first, such a man may lose time by puzzling over the job, but, once he gets to know his machine, he will not readily be put in a fix. It is always advisable to have a man available to instruct others when they begin this work. As soon as a drill needs repair, or refuses to work, it should be sent to the surface, as it is a loss of time to undertake to repair it underground, and one is liable, in so doing, to lose some of the fittings.

The machine-man must know how to point his holes and how to fix his support where it will enable the drill to command the greatest number of holes. In operation, if a column or shaft-bar is to be used, place a block of wood between the rock and one end of the bar, though a block at each end is always to be preferred. Fix the bar firmly and rigidly between floor and roof or the walls by means of the jack-screw. Now clamp the drill tightly on it in the required position and square off the rock, where the drill is to enter, at right angles to the travel of the bit. This should be carefully attended to, especially in hard fissured rock, since the bit, under the heavy blow, will glance aside, and not cut down the edge of the hole in line with the travel of the bit. This deviation, if not attended to, will gradually carry the bit so much out of line as to waste the whole effect of the blow in friction, whereupon a bit of smaller size must be inserted. In fissured and troublesome rock, when the drill is allowed to get out of line at the start, it will often cause trouble throughout the entire hole, while *a hole well started is half drilled*.

When the face of rock has been squared, and everything is ready for a start, put in the shortest bit, which will permit a good travel of the feed screw, draw out the piston-rod until the piston strikes the bottom of the cylinder, and screw forward the drill until the bit touches

the rock, then give the feed-screw a couple more turns. To fix the bit in its chuck all that is necessary is to force back the piston-rod, then draw it smartly forward, striking the bit against the rock. Then tighten the U-bolt nuts. Permit air to blow through the hose to remove any dirt or grit which may have accumulated, close the throttle-valve, pour two tablespoonfuls of oil into the coupling, bend the hose and connect it to the machine. Oil the rotating gear by removing the screw-plug upon the top cover and the machine is ready to start.

Turn air into the hose from the mains, half-open the valve, when the machine will start and at once begin to cut the rock, and, as the bit penetrates the rock, the machine must be correspondingly fed by the feed-screw. When four to five inches have been drilled, turn on full air, pour water freely into the hole and keep turning the screw-feed as the hole advances. When the short drill has cut as deep as it will reach, shut off the air, get the machine back by means of the feed screw, remove the bit and replace it by the next longer one. Strike the first few blows at half-pressure to bring the bottom of the hole to the shape of the drill, then proceed at full speed as far as that bit will allow, when it in turn must be replaced by a still longer one, and so on to the depth desired.

In running a new machine-drill *with steam*, it may happen that it will not start readily, or at first to work slowly. This is caused by the unequal heating of the cylinder and will disappear as soon as the machine becomes uniformly heated. When starting either a new machine, or one which has been laid aside, pour a half-pint of coal-oil into it to remove the gum of the old oil, and, after a few minutes' run, oil with a good suitable oil. Keep the machine properly oiled, take care of it, and you will find it the miners' most useful tool, and one which will last for years with trifling repairs.

To those who are practically conversant with metallurgical operations no argument need be offered as to the value of properly made calculations concerning the running of a process. If ever rule-of-thumb is to be placed in a metallurgical process by scientific operation, the change must be based upon experiments, classification of results, and calculations therefrom. The principles involved are physical, chemical, and mechanical; the scientific metallurgist must master these, use them as tools, and overcome brute nature by their skillful employment. Every metallurgical problem is an exercise in pure logic and mathematical reasoning; the premises are observed facts—all that can be learned of the process by direct observation and measurement; the conclusions desired are everything which can be deduced from the process by hook or by crook, by direct logical process or by inference. In this way data and information are obtained, which cannot be directly observed or measured, and which are of the most essential value for thoroughly understanding the process.—Jos. W. Richards.

THE MOST POWERFUL LOCOMOTIVE.—What is said to be the heaviest passenger engine ever built has been delivered to the Lake Shore & Michigan Southern Railroad. It weighs 244,700 lb., of which 170,000 are on the driving wheels. The engine and tender weigh 403,700 lb. and the capacity for water is 7,800 gal., while that for coal is fifteen tons. This powerful locomotive was designed as a step in the development of large passenger locomotives on the Lake Shore road, which began about seven years ago, as a result of which this road has a series of successful designs. The Walschaert gear has been generally adopted because of favorable experience in both freight and passenger service. The new locomotive is entirely free from untried devices or principles.

Three Weeks in Mexico---IV.

Geology of the Mines at El Oro.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

From Mexico City I went to El Oro. This mining district is 90 miles northwest and while most of it is within the State of Mexico, its northern portion extends into the adjoining State of Michoacan. At the time of my visit (October, 1905) El Oro was attracting much attention; a new orebody in the Esperanza had sent up the shares (of the company owning that mine) in London; El Oro Mining & Railway Company shares had risen in sympathy; Dos Estrellas was making a boom market in Mexico City; and Victoria y Anexas was fluctuating in a manner beloved of speculators. As a foundation for such financial activities, I found lodes of unusual geologic interest

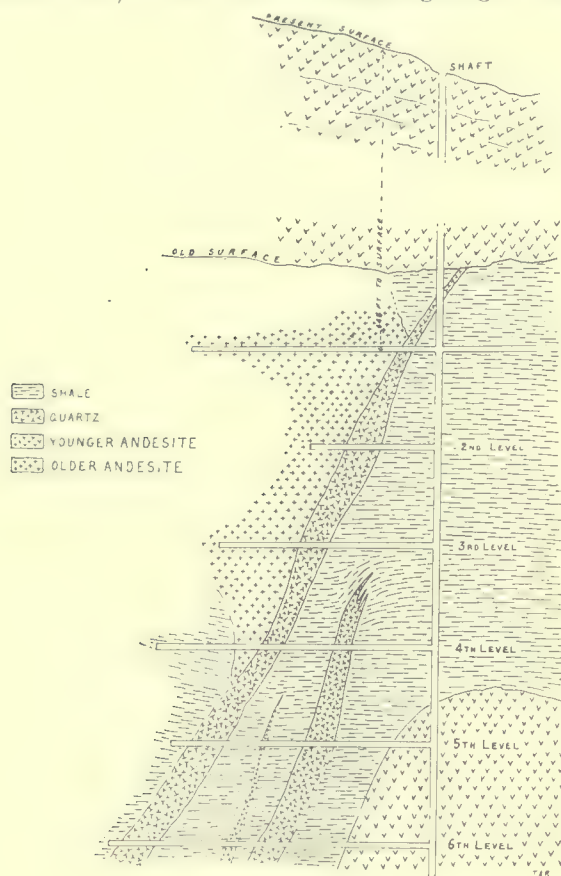

Fig. 1.

and a metallurgical practice that represented the sum of great technical ability.

The mines are situated on the slopes of a ridge that rises 600 ft. above the valley, through which runs the old main line of the Mexican National Railway. On the near (eastern) side are the Mexico, Esperanza and El Oro mines; on the further slope is the Dos Estrellas. The three mines first mentioned follow a series of veins of which the San Rafael is chief; these dip into the mountain. The Dos Estrellas on the other side also dips to the west. The bush-covered summits of the ridge consist of an andesite lava, while the mine workings are mainly in shale. A covering several hundred feet thick of (probably Pliocene) andesite is spread over the ancient eroded surface of a (probably late Cretaceous) shale, in which occurs a series of quartz lodes, containing gold and silver. The cap-rock forms part of an extensive extrusion of volcanic material, the main vent of which is not known; although in the mines there have been encountered tongues and irregular bodies of the same rock, suggesting many minor places of emission. The shale is thinly laminated, black, and calcareous; it contains occasional layers of limestone. According to Robert T. Hill, it is

the formation in which occur many of the best mining districts of Mexico. The relation of the cap-rock, the shale, and the quartz lodes is seen best in the Mexico mine, which, being a young property, is easily accessible throughout. The accompanying cross-section (Fig. 1) through the main shaft is based upon a tracing given to me by Mr. Fergus L. Allan, superintendent of the mine.

The shaft goes through the andesite of the cap-rock for nearly 600 ft. and then penetrates the shale. After passing through this shale for 450 ft., the shaft encounters andesite and continues in that rock to the bottom, just below the sixth level. This andesite, in the foot-wall country, is the same rock as the cap, and is evidently younger than the vein and, therefore, later than the other andesite which overhangs the San Rafael vein, as seen in the first four levels west of the shaft. Some distance west of the San Rafael vein in the Nolan mine, narrow

Fig. 2.

intrusions of this younger andesite have been found running at right angles to the course of the vein. The deeper levels have not found the older andesite on the hanging wall; it antedates the vein, for mineralization extends into it. The same tongue of andesite occurs in the northern workings of the Esperanza and in the same position relative to the vein. In some places ore has been found in this andesite, where it is adjacent to an orebody in the vein.

The lode consists mainly of banded quartz, built largely of rock in place, which has been shattered and silicified, the whole body attaining a width of 30 to 50 ft. The ore occurs in pay-streaks along the walls of the vein, in some places combining and occupying the larger part of the space between. This quartz contains just enough iron oxide to color it; when banded it is always good, the poor portions of the vein being characterized by massive white quartz. The shale adjoining the vein is bent and shattered, it shows numerous streaks and small veins lying parallel to, and running into, the main vein. That portion of it which is found at the old surface of the shale has a width of 30 to 40 ft.; it had evidently undergone erosion before being covered by the later andesite capping.

As a rule where the apex has been thus exposed to weathering, the San Rafael vein is richer than usual; it has undergone a noteworthy concentration. In the southern portion of the Mexico mine the apex of the vein is found at the surface of the shale, but further north the vein stops 100 to 250 ft. below the old surface of the shale. When the vein does not reach the old surface, it frays out into stringers, bent over at their ends, as shown in Fig. 2. This particular vein carries an average assay-value (11 dw't. gold and 6 oz. silver) right from the start; it widens until, at the fourth level, there is 25 ft. of quartz; on the second level, only 25 ft. above its blind apex, there is no indication whatever of the proximity of a vein.

The conditions just described as occurring in the Mexico mine are found in the Esperanza and El Oro workings, which extend in sequence southward.

As seen in El Oro mine, the veins really constitute one big lode-channel with portions of country between, that

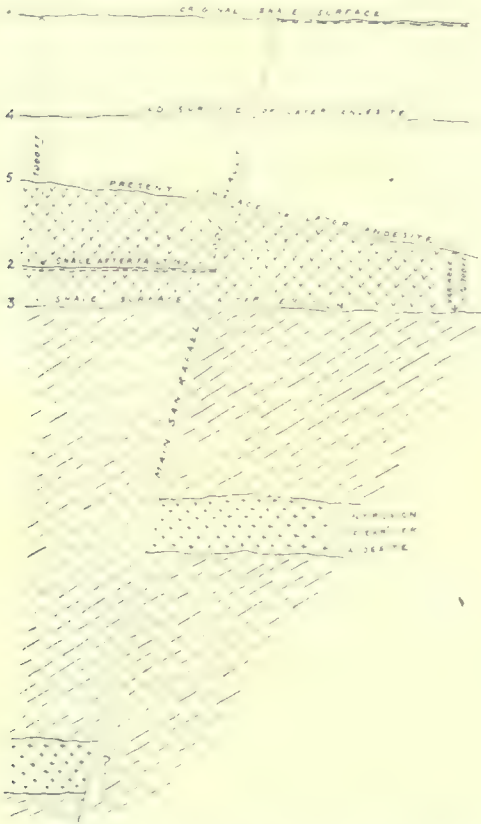

Fig. 3. Diagram Showing the Series of Geological Events Which Brought About the Present Structure. Cross-Section of Northern Portion of Esperanza Mine.

is, the distinction between what is ore and what is worthless quartz is purely commercial, based on assays, and not upon geological or structural distinctions. At first the Branch vein, one member of the system, was found to be rich enough to exploit; then a smaller streak on the hanging wall of the big Main vein (the San Rafael) was worked, and finally the foot-wall portion of the San Rafael was stoped, to be followed by various subordinate members of the series, as they were determined to be rich enough in gold and silver, to more than meet the costs of mining and milling. A typical cross-section of the lode-channel shows sundry branch veins, then the foot-wall orebody of 35 ft., then streaks up to 3 ft. wide between the foot-wall ore and that of the hanging, which is 40 ft. wide; finally, beyond these there is the Branch vein, 5 to 18 ft. wide.

At the north end of the mine the orebodies of the foot and hanging are separate; they come together in a distance of 700 ft. and form one width of 80 ft., which

is maintained nearly to the south end of the shoot, in the vicinity of the incline shaft. The ore on the hanging is fairly uniform in value across its full width, the foot-wall ore is best on the hanging side; even after they unite the individuality of the streaks is maintained. When the bands of pay-ore in this mine terminate they do so first by narrowing and then by the splitting or fanning out of the mass of quartz that contains them. Divergent streaks connect the various orebodies, and some of them are rich enough to be stoped. The whole lode-channel is

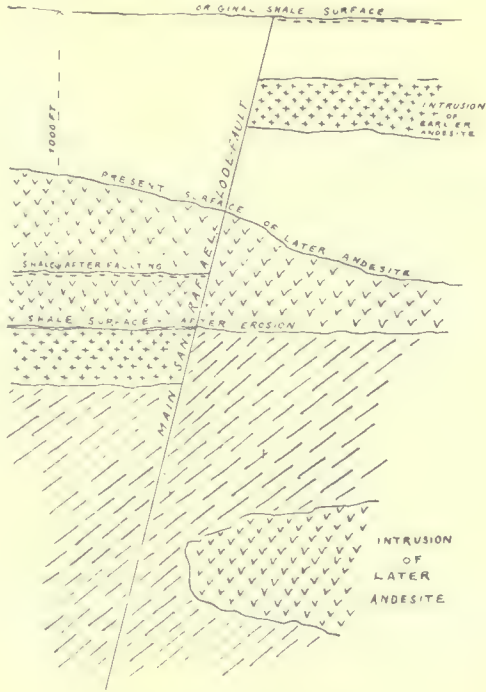

Fig. 4. Lode Fault, San Rafael Vein. Cross-Section of Southern Portion of Esperanza Mine.

interrupted at intervals by a succession of faults dipping at 65° to 70° except the southernmost or diagonal break which is 35°; all of them dip north.

Water was first struck in El Oro mine at 425 to 430 ft. below the cap—for all measurements are made from this old surface. Maximum water was encountered at 1,200 ft. The Somera shaft began to show a heavy inflow be-

Fig. 5. The Esperanza Fault. After J. E. Spurr.

tween 786 and 1,000 ft., especially from 900 ft. down; the water came in along stringers on the hanging-wall side of the lode. At 1,000 ft., the cross-cut (90 ft. long) to the lode cut more water along other veins, so that when the lode was finally struck there was no great addition to the inflow. The water in the workings on the main lode remained at the 786-ft. level until the lode itself was cut at 1,000 ft. The faults appear to be impervious and serve as barriers; each block has to be drained

separately. At the end of the rainy season, surface-water makes itself felt in the mine, but only in the northern workings, where it seeps down through cracks in the cap-rock caused by mining operations, more particularly the large stopes on the San Rafael lode made by the Esperanza and El Oro companies near their common boundary. The rainfall apparently does not affect the inflow of water in the deep workings, the mine-water (except in the case above noted) having no direct connection with surface.

In the Mexico and El Oro mines there is some geology, which is not particularly complicated; but the ground between, occupied by the Esperanza mine, presents many intricate problems.

There is a good deal of geology in the Esperanza, and there is a good deal of rich ore. The geological features have been carefully studied by Mr. J. E. Spurr, and the data embodied in my notes are largely the result of his work, in association with the management. The accompanying diagrams (Fig. 3, 4, and 5), and the geological plan of the second level, as given in Fig. 6, are based on sketches and a blue print given to me by Mr. W. E.

with the shale, as is suggested by a tongue of that rock indicated on the diagram. In Fig. 4 the same sequence is exhibited as is seen in a cross-section of the southern end of the mine. In this case a higher intrusion of earlier andesite is shown and also a tongue of later andesite.

The lode, therefore, follows a big fault; but it is itself faulted, as shown in Fig. 5, which is a longitudinal projection N. 60° E., magnetic. On the first level at a point 525 ft. north of El Oro boundary, this fault cuts through the country and displaces it, as measured by broken ends of intruded older andesite, 500 ft. vertically. This same fault is evident at the surface of the shale (now buried under later andesite), for there is a drop of 160 ft. in the bottom of the cap-rock. This would appear to indicate that the movement transverse to the lode continued after the later andesite overflow, so that in the main fault, the total dislocation is measured in two parts, two-thirds or about 340 ft. of which occurred before the cap-rock was formed, and one-third, or 160 ft., after that event.

In the mine the lateral displacement of the San Rafael lode is 130 ft. to the right. At the south shaft the cap

Fig. 6. Plan of Second Level of Esperanza Mine.

Geology by J. E. Spurr. Drawing prepared by the author from map by W. E. Hindry, mine manager. The apparent anomaly in geological conditions—the andesite being absent on the south side of the fault—is explicable by the fact that there has been a vertical displacement, as well as the horizontal movement indicated. Comparison should be made with Fig. 1, this section of the Mexico mine being taken 800 ft. north of the ground shown in Fig. 6.

Hindry, the manager. To him and to Mr. W. H. Haynes, the assistant manager, I am much indebted.

The main geological events, the results of which are evident in the mine workings, are:

1. The deposition of the shale.
2. Intrusion of andesite in the form of dikes and sills.
3. Faulting, involving several dislocations, one of which became the channel of the San Rafael lode, and later movements that displaced it.
4. Deposition of ore by waters circulating along the channels made by the previous fracturing.
5. Eruption of a later andesite that overflowed at surface and penetrated the shale formation.
6. Cross-faults.

In Fig. 3 the San Rafael lode is shown as seen in cross-section, looking northwest, in the northern portion of the mine. The sequence of geological events is indicated by the numbers 1 to 5. First, the shale was ruptured and dislocated at least 1,000 ft.—from 1 to 2. Then it was eroded and on it was spread the andesite, the original surface of which at 4 was reduced by erosion to the present surface at 5. The thickness of this andesite cap ranges now from nothing up to 700 ft. In the meanwhile the intrusions of earlier andesite were also faulted

is 284 ft. thick; near the north shaft it is 165 ft. higher (by reason of the rise in the ground in a length of 1,600 ft.—the distance between the shafts) plus the fault (160 ft.), plus the elevation, making the present thickness 165 + 160 + 284, or 619 ft. South of the fault the lode is entirely in shale all the way down to the fifth level; just below that horizon there is andesite on the foot-wall and shale on the hanging. North of the fault, the first level penetrates cap-rock, while the second has shale on the foot and the older andesite on the hanging. The third and fourth levels repeat the conditions observed on the second. At the fifth (still north of the fault) there is a change; at about 100 ft. in the foot-wall the newer andesite (which is the cap-rock) appears at 500 ft. north of the fault and thence to the boundary of the Mexico mine. At the sixth level the older andesite shows in the foot-wall south of the fault and appears to be the top of an intrusion, while north of the fault shale appears on both foot and hanging, that is to say, we have the conditions which exist south of the fault 500 ft. overhead—which is the measure of the dislocation. On the seventh level the older andesite appears along the foot-wall up to the fault, shale showing in the hanging. North of the fault the lode is in shale as regards both walls, with the

newer andesite in the foot-wall country (150 ft. east of the lode) near the Mexico boundary. At this same level—the seventh—the newer andesite (or cap porphyry) occurs

Mexico, Esperanza, and El Oro mines. The interesting problem, during my visit, was whether the new West vein is faulted (See Fig. 6) in a manner similar to the San

El Oro.

El Oro, Mexico.

Esperanza.

Mexico.

No. 1 Sulphide Vein. Third Level. Esperanza Mine.

In the form of an east-west dike, 153 ft. thick, at a point 825 ft. west of the lode, but its real shape has not been ascertained.

All this refers to the San Rafael, the main lode of the

Rafael or whether this bonanza vein is younger than the fault itself. If the latter be the case, the vein would go into the andesite north of the fault at the third, fourth, and fifth levels. The ore of the San Rafael extended up

to the fault, the break being clean. At the fifth level pay-ore was broken almost up to the fault-line. The San Rafael is generally more broken on the north side, the ore not reaching up to the fault as clearly as it does on the south side. If the West vein be later than the fault, it is likely to be weak where crossing the latter and probably it will be less rich in the andesite than in the shale, the bonanza portions of the veins of El Oro district being in shale country. With the limited data at my disposal, it seems to me unlikely that the new vein is younger than the fault, because there is no evidence of its existence in the northern workings.

The new Esperanza orebody was a sight to gladden the eyes of a miner. It is 680 ft. long, with an average width of 9 ft. and an average yield of 75 grams gold (or \$49.70) per ton and 1,150 g. silver (\$19.55) per ton. The shape of it is roughly lenticular; it is widest about the centre and comes nearly to a point both north and south; in depth it is shaped like the bottom of a boat, with protruding keel. Where first cut on the fifth level, there were two veins close together—the first assayed \$1.50 to \$2 per ton, while the other, No. 2, to the west, went \$75 per ton. Subsequent stoping gave a different story; the No. 2 has been payable only for 50 ft. above this level, while the No. 1 gets into rich ore three feet above and only 15 ft. south of the cross-cut.

At about 45 ft. south, the two veins come together and make a width of 35 ft. of ore worth over \$100 per ton. The moral is: If you find absolutely nothing by drilling, do not cross-cut; if you find any encouragement whatever, cross-cut. In the workings that I visited there were stopes four feet wide of ore worth \$500 per ton; where the quartz was rich, even the adjoining shale (penetrated by small stringers of quartz) was good enough to stope, for it assayed 15 to 40 grams gold.* Small bands of shale included by the vein assayed equally with the quartz. It seemed to me that, as compared with the San Rafael lode, this bonanza vein was particularly definite; there was no gouge and the shale at the walls was broken off clean, without shattering or twisting, the bedding of the outer country lying flatly right up to the ore. The vein is apparently younger than the San Rafael, because there are few signs of later movement, such as slips or gouge-seams. The ore itself is beautifully ribboned; minute crystals of pyrite encrust the quartz, especially in geodes or vugs; the richest ore is *moscado*†—that is, speckled with argentite.

On the seventh level there is an interesting vein occurrence; this is a sulphide streak, 26 in. wide, in the foot of the San Rafael lode, which here is 22 ft. wide. The sulphide streak crosses the San Rafael and is therefore younger. The foot-wall country in this part of the mine is porphyry (andesite) and the sulphide streak is built up of brecciated porphyry, the hanging being irregular and penetrated by quartz veinlets, while the foot-wall carries a gouge, beneath which the fragmentary character of the vein-stuff is evident. This vein carries a pyrite which is coarser than that of the new West vein and in the ratio of 12%; the West vein yields one ton of concentrate to 16 tons of crude ore, that is, over six per cent.

In speaking of ore at El Oro as being worth so many dollars, it is meant that it contains so many pennyweights of gold, for the silver is not included. This is largely a habit inherited from the days when the silver was not extracted to any considerable degree. A \$7 to \$9 (or 7 to 9 dwt.) gold ore will carry \$1.50 to \$2 or 2.5 to 3.3 dwt. silver per ton. The gold is free and in fine particles, rarely visible, while the silver occurs chiefly as the sul-

phide (argentite), with some chloride in the upper levels. The quartz is extremely hard and flinty, beautifully ribboned in lines parallel to the walls of the lode. In this respect and in its general appearance it often reminded me of the ore produced by the Amethyst and Last Chance mines at Creede, Colorado. Argentite occurs along the lines of ribboning in minute streaks between seams of opalescent quartz; the natives call these *hilos*, or threads. The ore is largely a replacement, by silicification, of the enclosing country and this holds true no less of the andesite than the shale. The Esperanza is sending mineralized porphyry to the mill and mineralized shale to the smelter. Beautiful pseudomorphs of quartz after calcite are frequent, they appear as sharp scalenohedra and resemble the 'water quartz' of Cripple Creek. The best specimens occur in the small horses (or included fragments of country) within the vein and on the outside of the big pay-streaks. All the surrounding shale shows effects of mineralizing activity and the outside andesite will often yield traces of metal; for instance, the old decomposed andesite on the fifth level of the Esperanza assayed 0.29 oz. silver and traces of gold.

At the time of my visit, at the end of October, 1905, the rate of production of El Oro district was slightly over \$1,000,000 per month, distributed thus: Esperanza, \$650,000; Dos Estrellas, \$240,000 and El Oro, \$200,000. An output of \$12,000,000, 82% of it gold, made El Oro the second most productive gold-mining centre on the American continent.

TRANSFER OF MATERIAL BY LAUNDERS.—The Butters' cyanide-plant at Virginia City, Nev., is situated some two miles below the town, and was placed there in order to work a large tailing dump which had been acquired by the company. The plant has no facilities for crushing ore, though a stamp-mill annex is now being built, consequently, when custom ore, as for example, Tonopah ore or low-grade ore from mines in town, was sought for treatment, the question of crushing and of delivery to the plant had to be considered. There is a mill in town containing eight Kinkead stamps, and of a capacity of 60 to 70 tons daily; it is conveniently placed for receiving and crushing the above-named ores, so that the cost of delivery would be low. Here the ore is crushed to pass a 40-mesh screen, and then passed over Frue vanners to remove the concentrate, which has as high a value as \$1,000 per ton, while the tailing, constituting the bulk of the ore, is put in excellent condition for cyanide treatment. The next question was how to deliver this at a distance of two miles to the plant situated several hundred feet vertically down the gulch. To do this a 12 by 12 in. launder was constructed conducting the tailing, containing twelve times its weight of water, to the plant. This it has done very effectively, the contained slime serving to stop the leakage at the numerous joints of the launders. The chief expense has been the maintenance of the line. While satisfactory in warm weather this plan has, however, failed in winter owing to freezing. In a country such as Mexico there would not be this difficulty to encounter. The alternative plan, about to be carried out, is to put in a two-mile aerial tram-line, delivering the coarse ore to the plant, and crushing it there.

THE causes which have combined to cast a single grain of sand upon the shore are infinite, and the infinite can neither be surpassed nor understood. We cannot understand what it is or how it comes to be where it lies, and yet we can make geology useful. Also, it is a maxim of science that results are obtained by approximation through error, and that the truths of one generation are the errors of the next.

* A gram of gold is worth 66.4c, and a gram of silver 1.7c. My description of the orebody is based, it must be remembered, on notes made at the end of October, 1905.

† From *mosca*, a fly.

Useful Definitions.

By S. F. EMMONS.

MATERIALS.

Ore.—*Ore may be defined as a natural association of minerals from which one or more of the useful metals may be profitably extracted. That such profitable extraction should be possible under existing conditions is not essential. Ores that do not pay to work today may become of great economic value a year or ten years hence without any change in the character of the ore itself. In describing an ore deposit the ores may be classed as payable or nonpayable. The common term for the latter in German mining literature is the prefix *taub*, signifying sterile or barren, but 'nonpayable ore' seems to be preferable to 'barren ore.'

Gangue.—This term is properly applied only to the earthy or nonmetallic minerals that are of common occurrence in ore deposits, such as quartz, barite, chlorite, fluorite, calcite, dolomite. The practice of regarding as gangue any metallic minerals that may happen to be of no economic value is not advisable, even if they be called metallic gangue, for it permits no uniform distinction between ore and gangue.

In describing the various minerals found in an ore deposit, it is well to distinguish the gangue minerals which are exogenous, or have been brought in from some outside source, from those which are the product of alteration of the wall or country rock.

Vein material.—As a collective term to describe the aggregate of materials which make up the orebody the phrase 'vein material' or 'vein stuff' may be used. 'Vein stone' is less desirable, for the reason that 'stone' is widely used among mining men as a technical term for valuable ore, and in England 'vein stone' is synonymous with 'gangue.'

Gouge.—Gouge or selvage is a soft, clayey material sometimes found between a vein and the country rock, and usually formed by the trituration of the latter by motion subsequent to the formation of the vein. The term should not be loosely used for any soft, crushed material.

Country or country rock.—'Country' is the miner's term for the rock which incloses an ore deposit. The term 'country rock' has been criticised as tautological; nevertheless, it is sanctioned by very general usage, and its use is considered advisable where the single word 'country' might lead to confusion in the mind of the non-technical reader.

FORMS.

Vein, lode, vein systems.—A vein is a single ore-bearing fissure generally, though not necessarily, with one or two well-defined walls.

When several veins are so closely spaced that the ground between them becomes in places ore-bearing and in its whole width constitutes an orebody, the assemblage is spoken of as a 'lode.'

'Vein system' may be used for a larger assemblage of vein fissures, which may include several lodes. The fractures of the earth's crust that admit of ore deposition are so multiform that it is not possible to give a stricter definition. Usage may vary somewhat in different districts, but the general order from simpler to more complicated fractures will be 'vein,' 'lode,' 'vein system.' The more subordinate fractures, such as little veins that cross the material included within vein walls, may be called 'veinlets' or 'stringers.'

Shear zone.—It is well to avoid a too general use of the term 'shear zone.' In one sense any vein could be called

a 'shear zone,' since its fissure was probably formed under some sort of shearing stress. On the other hand, 'shear zone' is more properly a term belonging to general geology, used to define the zone along which the rocks have been sheeted or laminated by a shearing stress with some lateral movement, but which is by no means necessarily or even frequently mineralized. If the term is used to designate mineral-bearing fissures in general, this distinction is lost sight of. It is therefore advisable to restrict its use to deposits formed along geological shear zones where the resulting water channels were so irregular that they can not be defined under any of the preceding heads.

Sheeting or sheeted zone may be used in cases where the movement has resulted in parallel fissures that have left thin sheets of country rock between them.

Bedded vein.—As rock fractures are independent of and generally cut across the bedding, the alternative form of deposit, as contrasted with a vein deposit, is one that conforms with the bedding, and has hence been called a 'bedded deposit.' Among miners the term 'blanket vein' is usually applied to any nearly flat deposit.

Gash vein is a term employed by Whitney to describe a vein that fills joints or fissures in limestone in the lead deposits of the Mississippi Valley region. It is a vein that does not extend beyond a given bed or similar rock mass.

True fissure vein.—This term was originally used by Whitney to describe a true vein as distinguished from a gash vein, the latter being limited in extent, whereas the former, according to him, "may be presumed to extend for an indefinite distance downward." From this statement apparently has sprung the idea common among miners that a true fissure vein is the most desirable form of mineral deposit, because of its indefinite extension. This is a popular delusion that it is not desirable to perpetuate; hence the use of the term should be avoided. 'True vein' was the term in use before Whitney's publication, and among the earlier writers on ore deposition signified a vein deposit filling a fissure; hence the term 'fissure vein' is in a strict sense pleonastic and should not be used in classification.

The following forms of structure may be recognized in the material filling a fissure opening:

1. **Banded structure**, where the vein materials show a banding approximately parallel to the wall. This may be subdivided, according to origin, into—

a. **Banded structure by filling**, where the filling is evidently the result of successive deposition of vein materials on the walls of an open space. If the layers are symmetrically arranged on either side of a central band containing druses with crystals pointing inward, this is called **comb structure**.

b. **Banded structure by subsequent movement**, which is produced by a simple sheeting of the vein material after original deposition, and is called **ribbon structure**. Sometimes such movement results in a re-opening along the new plane of movement and the deposition of new material in the opening.

c. **Banded structure by replacement**, where the original fissure consisted of a number of parallel openings separated by thin bands of country rock and where, during or subsequent to the filling of these openings, the intervening bands of country rock have been more or less completely replaced by vein material.

2. **Breccia structure**, where the friction breccia or dragged-in fragments of country rock constitute a considerable portion of the vein filling, and the ore has been deposited in the spaces between the fragments, often in more or less concentric shells or layers around them. Breccia structure may occur in any vein; hence it is not

* Abstracted from 'Suggestions to Authors of Economic Papers' by S. F. Emons. United States Geological Survey.

desirable to use 'brecciated vein' as a term of classification.

Some of the variations of the vein deposit are as follows:

Linked veins.—These are deposits filling approximately parallel and overlapping fissures, arranged en échelon, and connected or linked by small, irregular cross-stringers. As the deposit pinches out on one fissure it is taken up on one of the overlapping fissures.

Stringer lode.—A lode made up of irregularly branching and anastomosing stringers or veinlets. The rock between the veinlets is frequently so much mineralized as to constitute ore, when the whole is worked as a single vein.

Chimney, stock.—'Chimney' is applied to orebodies which have not the tabular form of a vein, but are rudely circular or elliptical in outline horizontally and have a very considerable vertical extent. 'Stock' is applied to a similar body of still greater irregularity of outline.

*Ore-shoot, pay-shoot.**—An ore-shoot is the richer portion of a deposit. A pay-shoot is that which is rich enough to exploit. While its outlines are not generally well defined, one can usually determine that it has a longer axis which forms a large angle with the horizon. The inclination of this longer axis is called the 'pitch' of the shoot, a term originally used to signify the inclination of the axis of a fold. It is not synonymous with 'dip,' though in a vein deposit the pitch necessarily partakes of the inclination of the vein or its dip. It has, however, a further inclination within the plane of that vein.

The true dimensions of such a shoot would be given by the length of its longer axis and the area of one or more cross-sections normal to such axis. Inasmuch, however, as its true form can rarely be determined, it is common practice to speak of its vertical extent, and of its length and width or thickness, as those of a horizontal section of the body on a given level of the mine. These are evidently not true dimensions unless the longer axis of the body is strictly vertical. It is advisable to follow the usage adopted by Messrs. Lindgren and Ransome in their Cripple Creek report and call the longer axis 'pitch length,' and the horizontal dimensions along the level 'stope length.'

Contact deposits.—It is advisable to restrict the term 'contact' veins or deposits, as has been suggested by Lindgren, to those which have been formed by contact-metamorphic agencies and which carry the minerals characteristic of such action. This use eliminates from this category many forms of deposit that are so termed simply because they happen to occur at the contact of two different kinds of rock without regard to their origin. Contact deposits, as thus restricted, occur mostly in limestone at or near its contact with an intrusive igneous rock. They are supposed to have been formed by gaseous or aqueous emanations from the cooling intrusive mass. They are very irregular in form and are often cut by eruptive dikes. Mineralogically they differ from other deposits by the contemporaneous formation of oxides and sulphides, principally of iron, and the association of the metallic minerals with the various lime-silicate minerals that ordinarily result from contact-metamorphic action. It must be borne in mind, however, that this mineral association may also result from regional metamorphism, but the resulting deposits differ from contact deposits in that the metamorphic processes have not introduced new or foreign material, but have simply altered or concentrated that which is already present.

Fahlband, segregated vein, impregnation.—As a general

rule care should be taken to avoid using the name of a process as the definition of a type of deposit. A number of terms that are useful in descriptions can not for this or for some other reason properly be used in defining types of ore deposits. Such are 'fahlband,' 'segregated vein' or 'segregation,' and 'impregnation.'

'Fahlband' is a local Norwegian term not generally applicable nor easily defined. It was originally used by German miners to distinguish certain bands of schistose rocks which are impregnated with finely divided sulphides and not in themselves rich enough to work, but which were thought to have exerted an enriching influence on the veins that cross them.

The other two terms define processes that may take part in the formation of many different deposits, and hence can not properly be used to characterize a single type.

'Segregated vein' has been used, for instance, to define materials that have been concentrated in a given sedimentary bed. The term would be more appropriately used for the material gathered together from a molten magma. In either case, it is not sufficiently distinctive to be used to characterize any single type of deposits.

The term 'impregnation' has been used by different writers in many and conflicting senses. It properly signifies the introduction of mineral substances in a finely disseminated condition into rocks, either as a filling of open spaces or as a replacement of certain minerals. To describe the occurrence of ore in small, irregular, disconnected patches throughout the mass of a rock 'dissemination' or 'disseminated deposits' is a preferable term, since it has no genetic signification.

PROCESSES.

Metasomatism.—This may be defined as the process by which, through chemical interchange, a mineral or an aggregate of minerals undergoes partial or complete change in chemical constitution. The term 'metasomatism' is of wider application than 'pseudomorphism,' in that it does not necessarily involve the preservation of the crystalline form of the original mineral. In large rock masses, as, for instance, in the metasomatic replacement of limestone by dolomite or by metallic sulphides, it often involves a change in volume, the resulting mass being more or less cavernous.

Replacement.—As a general term synonymous with 'metasomatism,' 'replacement' is preferable to 'substitution,' since the latter is a chemical term strictly defined as "the replacing of one or more elements or radicals in a compound by other elements or compounds," a restricted usage to which 'replacement' is not confined. Replacement may be either partial or complete, according as only a part or the whole of one rock or mineral has been replaced by another.

Alteration.—The term 'alteration' applies to the partial change of substance in a rock or mineral which does not necessarily involve its replacement by another. It is a purely chemical process.

Decomposition.—This term signifies a dissolution of a rock or mineral into its component parts, which involves a physical as well as a chemical change. It occurs most commonly during the process of weathering.

Weathering.—The term 'weathering' should be confined to changes in cohesion and composition of rocks near the surface that are due to the decomposing and oxidizing action of surface waters. Its tendency is to destroy the rock as a geological unit. The German usage of *verwitterung* to cover all changes due to weathering, thermal action and other causes, is objectionable, since it is liable to lead to misconceptions.

* Sometimes wrongly written 'chute' which is a French word signifying fall and properly applicable only to the artificial passages through which ore falls to a lower level.

Developing a Prospect.

Written for the MINING AND SCIENTIFIC PRESS
By ARTHUR LAKES.

One of the mistakes in mining that has ruined many promising young properties, is the attempt to prove and

Fig. 1.

develop a vein high up on a mountain, by a long and costly cross-cut driven from the cañon far below. Hundreds of abortive 'tunnels' of this kind may be seen lying idle in our steep mining regions, the majority having never reached half way to their intended goal. A few have gone beyond, and missed the vein. Most of them are failures. The explanation may be as follows:

No. 1. The distant stockholders of the company grew tired of hearing nothing about ore or of the development of their claim except the costly slow progress of an indefinitely long adit, and therefore failed to send more money.

No. 2. The ground proved harder as the adit was advanced, more costly to work, and longer than originally estimated.

No. 3. The vein sought for was mistaken for another which proved barren.

No. 4. The real vein was passed without being recognized, and the adit was carried into the country rock until a halt was called.

Fig. 4.

No. 5. In the progress of the work the miners wandered here and there, tempted by this and that sign of ore until the adit lost its direction, or the direction may have been altered by contractors who were seeking soft rock and shunning the hard.

No. 6. The company found, as the work progressed, that it was being assessed for things not originally con-

templated, such as air-compressors, machine-drills, etc., to continue the work and maintain ventilation.

Of these various difficulties and disasters in long cross-cuts one of the commonest is the failure to meet the vein in its entirety or to recognize it or its representative when actually cut at the point where, on the assumption

Fig. 2.

of a uniform dip from the surface, it might reasonably be expected. The vein when struck may appear at the point of section, so small, insignificant, and barren, that

it is assumed not to be the same as the large promising vein on the surface. Or instead of a vein, only a barren narrow crevice, a watercourse, a mud slip, or a zone of crushed rock, may appear as its representative and the adit is advanced into the country, groping blindly for the expected ore.

Suppose that the angle or degree of dip should change with depth, either by steepening or lessening, or by a series of steeps and flats, or be materially deflected by faulting, then a calculated point where the vein should be cut may be considerably off, especially at so great a depth as between 500 and 1,000 ft. Under any hypothesis, the distance to

the vein is almost sure to be greater than estimated or even surveyed, and if there was no accurate survey the distance to the vein will certainly be exaggerated, for the slope of a mountain to the unaided eye is

Fig. 3.

Fig. 5.

exceedingly deceptive in calculating underground distances. While the prevailing mistake is to aim at getting too great depth, we have known adits being run a thousand feet to get a depth of less than one hundred.

The vicissitudes of a vein, such as change of dip, faulting, pinching, widening, splitting by 'horses,' long intervals between ore-shoots, and the like, are familiar to

any miner who has worked in our deep mines, and he knows the 'hit or miss' possibilities which such involve in the case of a long cross-cut 'tunnel' to the vein.

In the steep cliffs on either side of the profound cañons of the San Juan region in Colorado, there are excellent opportunities of observing the downward course of great fissure veins for a thousand feet or more, and such object lessons might well intimidate the projector of long deep cross-cuts. These great veins as they descend the precipice are seen to be split by 'horses'; to wander or branch off into the country rock; locally, or for long stretches they pinch almost to nothing, and widen again; their downward dip and course may be irregular, sinuous, or materially broken and deflected by faults, by cross-courses or by other veins.

In veins in schistose or thin-bedded strata nearly conforming to the sinuosities of the bedding planes, veins occur in lenses along ill-defined lines and at irregular distances, separated from one another by barren ground or connected by slight uncertain traces of vein-matter or by no trace at all other than the slickensided walls of a narrow crevice. It is obvious how perilous would be the task of striking the particular vein desired when the country abounds with veins and mud-slips, by a long 'tunnel' driven at great depth below the upper workings.

In some districts veins showing well and producing heavily near the surface are notorious for giving out in their orebodies at moderate depth. Long adits to tap at great depth such uncertain veins have, for the most part, failed.

Apart from variability in direction and inconstancy of ore-shoots in fissure veins, there is a risk from change of rock formation. Thus, in the San Juan region, the productive fissure veins for the most part occur in, and are confined to, a very thick mass of volcanic breccia resting on up-tilted sedimentary beds (Fig. 4). On leaving the breccia and entering the sedimentaries the fissure may cease abruptly, or if continuous, be exceedingly poor or totally barren. A cross-cut driven below into the sedimentaries would fail in its object and a raise would have to be run a long way into the breccia to find a productive portion of the vein.

Omitting the extremes, such as developing an unproved hilltop prospect by a long adit a thousand feet or more below it, let us take the common and more moderate one of development by a 'tunnel' 1,000 ft. long with a projected upraise 500 to 600 ft. on the vein. This scheme, in my opinion, is 500 ft. too long and the upraise 300 ft. too high.

One of the principal difficulties of such an undertaking is that of air and ventilation. Naturally air from the entrance, augmented by a furnace and pipe, and later by a fan, may answer for a while, but when great length is attained and when it comes to rising on the vein this will not suffice. The difficulty may be overcome partly, by using an air-compressor and machine-drills.

Suppose the vein to be struck eventually and a raise begun. In such work a hoist, either by steam or air, becomes a necessity, and it is soon found imperative to get an outlet to the surface either by driving along the vein or by a cross-cut. If such short cross-cuts from the vein become necessary, would it not have been better from the first to have attacked and proved the vein by a series of short 'tunnels' driven from the surface at moderate intervals successively down the hillside than to have recourse to the expense of the long adit, with all its cost, risk, and difficulties? One of the advantages of the short cross-cut at shallow depth is that in case of missing or failing to cut the vein, raises can easily be made to the vein where it is in place. In the long deep adit such experiments are too costly.

In a young property the aim is not to plan the future

development of a great mine, but to prove and show what you have, whether the vein and ore go down, whether or not the property is prospectively valuable, and is worth working. The mistake of the long adit is that it plans for the future development of a mine on a grand scale before it is actually known with any degree of certainty what there is in the prospect or whether it has any chance of becoming a mine at all. Obviously, the best way to proceed with a young property is to begin above and work gradually downward, whether by shaft or short cross-cuts at intervals, or by both shaft and tunnel. This plan keeps the operator close to the vein and brings to the minimum the risks of losing the vein.

No hard or fast rules will fit all the circumstances and positions of prospects in the field. What might fit in one case would not do in another. What might be excusable in one case would be folly in another. Long adits may serve their purpose in the maturity of the mine when compelled for drainage purposes.

The accompanying illustrations show conditions sometimes encountered by cross-cuts to the vein.

Fig. 1 shows a fissure vein dipping into the mountain away from the slope and contour of the hillside. At first the dip is deceptively gentle, but it soon steepens. With depth, faults are encountered; these deflect the vein and cause the adit to be longer than anticipated.

Fig. 2 shows a vein conforming more to the slope, but in depth deflected inward by a fault. A cross-cut misses the vein by striking the line of fault.

Fig. 3 shows a big fissure vein like those in parts of the San Juan. A large 'horse' occurs part way down, and the thickness of the vein is reduced to a minimum. Lower down its course is deflected by a cross-vein, and below that the vein splits up into three branches, which may eventually come together.

Fig. 4 shows the risks of a cross-cut in lenticular veins. The cross-cut aims at reaching the contact with the igneous rock, but though there is sometimes a vein or ore deposit at such a contact, there are intervals of barren ground or 'tight' contact.

Fig. 5 shows fissure veins in one formation, as in the volcanic breccia of the San Juan region, becoming barren in an underlying sedimentary zone.

THE SUEZ CANAL is being deepened to give 31 ft. of water so as to allow of taking vessels of greater draft; at present the depth prevents any material increase in the size of steamers of the various lines between British and Oriental ports, while some large battleships have to transfer their guns to lighters and go through with coal-bunkers almost empty. In 1902, the permissible draft was increased from 25 ft. 7 in. to 26 ft. 3 in. In connection with the deepening, the curves are being improved and widened, and at certain points the bottom width is being increased from 102 ft. to 128 ft., while in the Bitter lakes the channel is being widened to allow ships to pass. The average width at the water surface is from 300 to 360 ft. in the northern part and from 240 to 300 ft. in the southern part. It is suggested that the entire canal should be widened to a bottom width of 150 ft., so as to enable ships to travel continuously in opposite directions instead of having to wait at passing places. One reason for this is said to be the promotion of a scheme for a rival canal. — *Engineering News*.

THE grandest, apparently most solid, eternal mountains, seeming so firm, so immutable, are yet ever changing and crumbling into dust. The shattered ridges are evidence of their sufferings. Every ridge of the Alps and every summit is surmounted by a piled-up heap of fragments.

In the Andes.

We are indebted to Mr. W. H. Shockley, now at Tonopah, Nevada, for the accompanying photographs and notes on an interesting mining region. They were obtained in the course of a journey to the Montebello mine in Carabaya, Peru, in Lat. 15° south and Long. 70° west. This portion of Peru was long renowned for its rich gold mines and in the days of Pizarro a mass of gold the size of a horse's head is said to have been sent to Spain. The trails to the mines cross the Andes at a tremendous height above sea-level; in this case the crossing was at Aricoma pass, at 17,000 ft. The character of the

many times on suspension bridges, made of rope as shown in Fig. 3. Two horses are in the act of crossing, one ridden and the other led; on the trail the remainder of the expedition is proceeding in single file. In the distance, up the valley, the clouds obscure the high peaks. These mists rise from the eastern side of the Andes and rise to the summit, where they encounter the warmer air of the Pacific slope and become dissipated. The trail connecting the Santo Domingo mine with the low country is only a narrow shelf blasted out of the solid rock, overhanging the river. In going to the Montebello mine, the trail at the highest point is 600 ft. above the ravine and for miles a stone dropped from the hand of a rider

Fig. 1. Glacier on the Aricoma Pass, 17,000-ft. Altitude.

Fig. 2. Summit of the Aricoma Pass.

climate is suggested by the glacier shown in Fig. 1; it being remembered that this body of ice is within the tropics. A large cairn surmounted by a horse's skeleton marks the summit of the pass, as shown in Fig. 2. In this province of Peru, near a place named Poto, is a mine

will fall 200 ft. vertically into the stream. The Montebello mines are at about 5,000 ft. altitude in the verdant montaña, or lower mountain land. They were worked many years ago, but the forge shown in Fig. 4 is about all that remains of the old buildings. Many 'tunnels'

Fig. 3. Rope Bridge on the Santo Domingo Trail.

Fig. 4. Blacksmith Forge at Montebello Mine.

that is probably the highest in the world, for it is close to a glacier at about 18,000 ft. We remember being told at the Sunrise mine, near Skipper's Point, in Otago, that that was "the highest in the world," though it was actually only 7,200 ft., or lower than any mine of importance in Colorado. But in Colorado they think they hold the record in this respect, the fact being that the highest mine is the Present Help, on Mt. Lincoln, at a few feet above 14,000. Our readers may be able to contribute other data on this question.

The trail that Mr. Shockley followed descends in 50 miles to 3,000 ft., on the Inambari river, which is crossed

now tenanted by the vampire bats are the only record of the work done long ago, but as modern energy spreads into these remote parts of Spanish America, they are destined to be explored and exploited.

It is worthy of remark that not only do fragments of such rock as limestone often present the characteristic forms of the cliffs from which they have broken, but that pieces of mica schist will represent, in a wonderful manner, the identical shape of the peaks of which they had formed a part.

Submarine Coal-Mining.

It is an interesting fact that there are now in Cape Breton six collieries working under water. The largest is the Princess or Sydney pit on Cape Breton Island. This colliery was the first in North America to mine coal from beneath the bed of the Atlantic ocean. The seam of coal averages between $5\frac{1}{2}$ and 6 ft. thick, of best quality. The angle of dip or inclination seaward is 5° . The working of the whole coal under the sea by the bore-and-pillar system was commenced in 1877, under an overhead cover at the shore line of 690 ft. of solid measures, although part of the workings driven to the rise under Sydney harbor, was operated under a cover of 500 ft. or less. The present workings are distant from the shore line 5,800 ft. on the dip. At this point the overhead cover is 1,140 ft. thick, with 33 to 40 ft. depth of water above it. The under-sea workings in the whole coal cover 1,620 acres. No sea water has yet found its way into the workings as the result of removing the pillars. A feeder of a few gallons of water per minute was encountered in some whole-coal workings driven to the rise, as also at the face of the water-levels driven in the direction of the outcrop to the south, but this water evidently followed the seam of coal downward from its outcrop under the water of the harbor. There has been no water known to come from overhead across the measures. This immunity from overhead leaks from the ocean is probably due to the presence in the superincumbent strata of beds of fire-clay or under-clay of a total thickness of 39 ft., as well as to the numerous beds of shale. The subsidence of the overhead strata caused by the removal of a bed of coal 6 ft. in thickness, would probably, under these conditions, soon choke itself, so that there would be no further actual motion or settling of the strata for more than, say, 100 ft. upward. Above that point the elasticity of the beds of shale and fire-clay mentioned would prevent any rupture. Fire-clay when brought into contact with water soon forms soft, plastic clay impervious to water. Out of the submarine area there has already been taken some 5,250,000 tons of coal from the main seam, while the company has also commenced the working of another and thicker seam in the same area, from which in all likelihood they will secure as much as has already been taken.

ELECTRIC SMELTING.—At a recent meeting of the Faraday Society, at London, Dr. Eugene Haanel presented a report on experiments made at Sault Ste. Marie on the smelting of Canadian iron ores by the electro-thermic process.

The furnace, which is fully described and illustrated, was of the Heroult type; it absorbed 5,000 amperes at 35 to 40 volts (power factor 0.919), being fed from a transformer of 225 kw. capacity. The official experiments, of which a selected number are explained in detail with full chemical, electrical and thermal data, lasted nearly two months, and during that time 150 casts were made, yielding 55 tons of pig iron. The experiments indicated that under normal conditions about 11.5 tons were produced by an expenditure of 1,000 e.h.p.-days; with an improved furnace of, say, 1,500 e.h.p. capacity, a figure of 12 tons should, it is stated, be reached. The mean figure provisionally adopted by the Commission was only 7.8 tons per 1,000 e.h.p.-days. The consumption of electrode was about 18 lb. per ton of pig iron; it was greater for white than for gray iron.

The results obtained are summarized as follows:

1. Magnetite (which is the chief Canadian ore) can be as economically smelted by the electro-thermal process as hematite.

2. Ores of high sulphur content not containing man-

ganese can be made into pig iron containing only a few thousandths of one per cent of sulphur.

3. The silicon content can be varied as required for the class of pig to be produced.

4. Charcoal, which can be cheaply produced from mill refuse or wood that could not otherwise be utilized, can be substituted for coke as a reducing agent, without being briquetted with the ore.

5. A ferro-nickel pig can be produced practically free from sulphur and of fine quality from roasted nickeliferous pyrrhotite.

6. The experiment made with a titaniferous iron ore containing 17.82% titanic acid permits the conclusion that titaniferous iron ores up to perhaps 5% titanic acid can be successfully treated by the electric process.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The red mineral from Spokane, Wash., marked M. H. H. is mostly earthy clay stained with iron oxide and including scales of mica.

The sample from Bodfish, Kern Co., Cal., is Magnetite—magnetic iron oxide—with a little earthy iron oxide and a small amount of argillaceous mineral.

The white rock from Glens Ferry, Idaho, marked H. W. B. is Rhyolite-tuff, a firmly compacted volcanic ash, including many rounded grains of quartz.

The rock from Eldora, Colo., marked J. K. D. is Granite with scales of specular iron ore. The black piece is principally specular iron, which is a variety of hematite (iron oxide).

The rock from Mazama, Wash., is Quartz-porphry, but is much altered and contains abundant calcium-carbonate, some of which has crystallized on the fracture planes of the rock.

The rocks from Sacramento, Cal., marked C. M. B. are from a basic dike, but its original character is completely obscured by alteration, the rock being serpentinized. It was probably originally gabbro.

The rocks No. 1 and 2 from Terrazas, Mex., marked D. G. are brecciated felsite, and contain a little iron ore, particularly No. 2. No. 3 is Feldspar-porphry and also contains ore. No. 2 and 3 should be tested for precious metals.

The minerals from Denver marked W. J. M. are: No. 1, Zinc-blende tarnished blue by copper salts; No. 2, Marcasite (iron sulphide); No. 3, Zinc-blende, pyrrhotite and chalcopyrite; No. 4, Quartz-mica-diorite-porphryrite; No. 5, Garnet.

The rocks from Naco, A. T., are: That marked A, Quartz, evidently the result of replacement of silica for the constituents of some intrusive rock—possibly rhyolite. It has now the appearance of being an ore. B is similar, though containing more iron.

The rocks from Penticton, B. C., marked A. J. D. are: No. 1, Feldspar with a few scattering bunches of fibrous hornblende; No. 2, a very silicious fine-grained greenstone; No. 3 is similar to No. 2, but somewhat darker, due to greater amount of hornblende present; No. 4 is coarse Biotite-granite.

La Mina Marques Manzanal.

This old Spanish mine, which has recently been re-discovered and opened, lies about 40 kilometres (25 miles) south of Cananea in Sonora, Mexico; it is in the Manzanal mountains, a group of hills taking its name from the mine. The mine was re-located on December 24, 1905, by Gaston Schwab of Cananea and is being cleaned out and explored. The ore is rich, and at a vertical depth of 160 ft. the vein is nine feet wide. Mr. Schwab has just purchased a good hoisting plant, sufficient to sink to 500 ft. There has been no stoping done but 400 sacks of high-grade ore assaying from 300 to 2,000 oz. silver and about 1 oz. gold and 30 to 50% lead per ton, besides a large amount of low-grade ore, has been extracted. The property is to be developed by an adit on the vein which will cut the shaft at a depth of about 300 ft. The old workings are remarkable from the fact that instead of the usual Mexican shaft (with notched log ladders) inclines were driven, one under the other (zigzag) at a convenient grade for walking up and down and carrying out the ore and waste in baskets on the backs of the miners, who were Indian slaves or prisoners. A number of old mining tools of iron and copper and the remains of an old copper lamp were found at a

depth of 120 ft. in the old workings, the copper of the lamp being in pieces and almost eaten away by corrosion; the iron drills and chisels are reduced to about one-quarter of an inch in diameter, the supposition being that they were originally about one inch in diameter. There was also another remarkable find, namely, the skull of a *jabali* or Mexican wild boar, on which was carved the following inscription: *Mina Marques Manzanal MDCCCLXII* (1812), and on the side a sketch of a chalice or communion cup used in the Catholic churches. The mines seem to have been hurriedly abandoned about this time, 1812, as the skeletons of two men, supposed to be Indian miners, were found in the first of the old workings opened at about 100 ft. from the surface. It is supposed they were killed while at work and left there by hostile Indians who no doubt caused the closing of the mines. The old workings have not been opened to any extent on account of being badly caved and full of debris.

*La Mina Marques Manzanal.*

INSTEAD of the surface of the earth being that stable, fixed thing that it is popularly believed to be, being, in common parlance, the very emblem of fixity itself, it is incessantly moving, and is, in fact, as unstable as the surface of the sea, except that its undulations are infinitely slow and very high and deep.

*Old Copper and Iron Relics Found in the Manzanal Mine. The Horn is Supposed to Have Been Used for Carrying Powder for Blasting.*

The Geologic Day.

By ALFRED C. LANE.

*It has been vigorously impressed upon us recently that 5:13 A. M. of April 18, San Francisco time, is not the same as Washington time, but about three hours later. Therefore the day ends and begins later at San Francisco than at Washington. The sidereal day is a little different from the solar day, the astronomical year from the civil year.

There is no reason to be surprised, therefore, if we find this to be true in dividing our geological time. We measure it generally by some slow change: the evolution of life, or orogenic movements, or the accumulation of salt in the sea, the changes in sedimentation consequent on elevation of continents, or changes in climate, like the passing away of the glacial epoch.

The post-glacial time for an illustration. It is clear that the ice must have retired from the valley of the Ohio before it retired from the Straits of Mackinac some time, and perhaps a very long time. Therefore the post-glacial epoch begins later at Mackinac than at Cincinnati. Yet I do not think it necessarily should have a different name, any more than April 18 has a different name for Europe and America. Of course there are difficulties, just as there are difficulties in saying what is the birthday of a child born near midnight, or near the date-line in the Pacific. But they are inherent in the facts, and are not lessened by introducing new terms, which indeed may lead one to overlook the realities of the case.

Difficulties have arisen from the fact that the lithological evidences of contemporaneity do not always agree with that furnished by fossils, and the early assumption (really a relic of the old cataclysmic theory, according to which God made one set of created beings, then wiped off his slate and began over again) was that fossils were the best and surest index of contemporaneity, in comparison with which all other factors or means of determination were of no weight.

No competent paleontologist now holds this extreme view, and many of them, like Williams, have shown clearly that fossils are not absolutely inerrant evidence of contemporaneity. Yet the influence of the old views, and the idea that the lines of a division of geological time must be lines separating different faunas, has so persisted that the tendency has naturally been, where the faunas proved misleading, to give up the idea of time entirely, and refer merely to homotaxis.

This will be a mistake. The idea of time is present in our geological divisions and their names, and though our divisions be imperfect expressions of our ideal, for that reason to throw away the ideal would be to make the same mistake as Hobbes, to whom a straight line was merely the straightest line he could draw, and who accordingly thought he had squared the circle, because he found a construction which was correct, so far as he could see.

It does not follow, however, that we should give a new name every time we find evidence of real difference in geologic time in the beginning of one of our geologic divisions. It should be carefully noted, and left to be weighed and compared with other evidences, until we are ultimately able to place each division at each place accurately on a true scale of time, which shall be to the common scale as is astronomer's time to the local times and seasons of everyday use.

Of these various evidences, fossils are by no means the best evidence of strict contemporaneity. Other evidences, as good or better, are:

1. A shower of volcanic ash like that which has

recently come from Vesuvius, if it can be identified, is the best evidence of contemporaneity. The same remark applies to a surface lava-flow. Individual lava-flows of peculiar character, like the foot of the Kearsarge lode, have been traced many miles in the Keweenaw, and great floods out West may, I presume, be equally contemporaneous. In time to come, geologists of the future may use volcanic ash-beds, among the series of shales and muds, which are overlooked now, as horizon-markers of the first importance.

2. The whole nexus of mud-flows, lavas, ash-beds, and the like, which make up an eruptive epoch, would not make so exact an index of contemporaneity, but in many cases are of considerable value. Keweenaw, and Triassic of the Atlantic coasts are illustrations both of the value and of the danger of such correlations. While indicating real contemporaneity, if the correlation is correctly made, there is likely to be an eruption of undistinguishable rocks at widely different times.

3. A change of climate may extend with great rapidity over a province or over a very large part of the world. The glacial period in Europe and America is one glaring illustration. Another is the change in the Carboniferous from the hot dry climate of the Mississippi to that of the Pennsylvanian. The change may, of course, have occupied considerable time in its spread, but probably only a fraction of the duration of each period. Salt beds, whether formed in desert wastes or inlets of the ocean, point to a dry climate.

4. If one could only get samples of water in which the strata were buried which had not changed in the meantime, one might, in the case of open marine strata, be able to date them from the progressive change in the character of the sea water. This may be of more value in the future than in the past, as it probably can be used only on water carefully preserved from deep borings in slightly disturbed synclinals where numerous beds are impervious.

5. Changes in the elevation of the land, and consequently in the shore-line, produce changes in the sedimentation in which climate may co-operate. These changes in the sediment-determining factors may be slow, like the tilting of the basin of the Great Lakes, now going on. But even in such cases they may be nearly simultaneous over long stretches of shore-line. They may also be sudden, like the uplifts of the South American coast described by Darwin. In general, it may be said to be likely that a sudden change, involving the injection of fine mud in the ocean water, is not likely to be extremely local.

The great advantage that fossils have is that they never come back to their original combinations. The course of life has never really gone backward, whereas sandstones, limestones, and shales of recent times may be undistinguishable from those of earlier times. Thus, when it comes to determining the general place in the geological column, to deciding whether the Lake Superior sandstone was 'New Red,' 'Old Red,' or coeval with the Cambrian fossils, if obtainable in sufficient quantity, far outclass other kinds of evidence.

If objection is made to using paleontology for the larger and broader time-determinations, and using various other methods for details, and not always drawing the line at the same place in using terms applied to these divisions in the different regions, we can again fall back on the analogy with the divisions of common time, where the sun rules the year and the moon long ruled the month, while the finer and more exact divisions depend on other data, and the year does not begin or end exactly at the same time at every place.

Editorial.

THE letter from Mr. E. A. H. Tays on conditions in Mexico states the facts plainly. It will prove satisfactory to those who want to see quiet maintained in Mexico, and to that increasing number of energetic men to whom our southern neighbor affords a profitable field of industry.

THE position of amalgamating plates in the stamp-mill is one which is open to discussion; the usual practice of attaching them to the front of the mortar causes vibrations, the usefulness of which is questionable. Mr. Percy Morgan discusses the matter in this issue.

MR. LEWIS T. WRIGHT gives us, in this issue, his final paper on 'Pyrite Smelting Without Coke.' He finds that, when using cold blast, rather less than one-third of the calorific power of the sulphur volatilized in smelting is effective, while with warm blast it was possible to diminish the percentage of coke in accordance with the heat developed by the increasing quantity of sulphur burned off, and finally with as much as 25 per cent of sulphur in the charge it should be possible to run without any carbonaceous fuel. In conclusion, he presents a table giving the heat requirements of a blast-furnace working without coke and shows that of the total heat developed the escaping gases carry off 39 per cent while the slag requires 25 per cent, the remainder being lost by radiation and by various minor causes. Another point brought out is that nearly 350 cubic feet of air is needed per pound of charge, which brings down the temperature quite close to the point of solidification of the molten materials of the furnace, approaching that temperature so closely that a hot, or at least a warm blast, is needed to bring the furnace above the critical temperature. This contribution from the pen of so well known a metallurgist is a distinct addition to our heretofore meagre information on these matters, and combines at once a profound scientific study of the subject with the results of prolonged practice in the treatment of low-grade sulphide ore, a practice worked up by Mr. Wright until he has eliminated the roasted ore heretofore considered a necessary constituent in blast-furnace operations.

WHEN one hears of so many new and large copper mines being opened up, it seems a wonder that the market is not glutted with the metal. As a matter of fact old mines are becoming exhausted as new ones are developed and accidents at one compensate for rich strikes in another. There is less said about the funerals than the births, for mines usually end their lives in a quiet unobtrusive way, however loudly their sponsors may sound the horn when they begin their career. Thus, in the Lake Superior copper district, where mining is conducted as successfully and on as sound a business basis as anywhere in the world, there have been several hindrances

to an increased production, although these are not heralded as freely as the good news from the great mines. In the first place, there have been labor strikes at the Quincy, Michigan, and Adventure mines, all of which have interfered with regular production. At the Tamarack a fire in No. 2 shaft has curtailed the output ever since January and the copper yielded by that mine for the larger part of the year is only three-fifths what was estimated. At the Atlantic the settling of the ground, due to an enormous extent of stopes, has finally caused a subsidence so general as to destroy the usefulness of the shaft and compel the abandonment of the workings, started thirty years ago. Another lode, known to exist on the property, is to be prospected, but this will not become a source of metallic wealth for an indeterminate period. These mishaps—strike, fire, and caving—are all among the ordinary chances of mining. The result is that the gain in production expected during 1906 from the Lake Superior mines will be cut in two. Even then the total yield will represent nearly one-sixth of the copper produced in the world.

Reformed Spelling.

On another page we publish a sensible and scholarly criticism of the reformed spelling by Mr. Benjamin Ide Wheeler, president of the University of California. The attempt to introduce new methods has provoked ridicule and even anger; it is now meeting with thoughtful opposition. Of course, a technical journal cannot assume any authority in such matters, for it is our duty to give information on scientific and industrial matters in whatever language is easiest understood by our readers; we accept what is considered the best usage and simply say what there is to be said with as little fuss about it as possible. To a certain degree the technical man stands between the hierarchy of science, which uses language the intelligibility of which is not required to extend among the unlettered, and those occupied in industrial pursuits, to whom language is simply a convenient tool, to be used, abused, or vulgarized, at will. Therefore, we only ask that the forms employed shall be understood among all those who speak the English language; for the engineer, metallurgist, or geologist is a man who makes the entire globe his field of action and he wants a vehicle of writing of the largest utility. He objects to peculiarities that may obstruct the exchange of ideas in America, Canada, England, Australia, Africa, India—in fact, wherever Anglo-Celtic energy is searching for metallic wealth and developing the waste places of the earth. The engineer is a citizen of the world and he wants no provincialism to hamper him. It is all very fine to say that Shakespeare spelt his name in 26 different ways, and that standardized spelling is a comparatively modern institution. We are glad to have emerged from such an orthographic chaos. Why revive it? Of course the 300 forms first launched by the Spelling Board are only the forerunners of other more numerous innovations, until the whole language has been modified to suit phonetic requirements. At the best we shall have twenty or thirty years of confusion, for only the next generation

will use the new spelling consistently; and if they do, in America, it is quite certain that other people speaking the English language will refuse to do so—partly from prejudice—, with the result that we shall return to the confusion from which we have only lately emerged. The early translations of the Bible are printed with spellings so diverse as to suggest different dialects, indicative of the locality where the translator lived. It is this provincialism of speech that printing has slowly overcome, until people who read and write have reached a uniformity sufficient to render them intelligible to each other, even though they retain differences of accent and pronunciation in their spoken language. The Englishman who pronounces 'here' like *hee-awe* and the Irishman who gives it the sound of *hearre* unite in signifying the same thing when they write *here*. Phonetic spelling will not induce uniformity of pronunciation because the signs used, namely, the letters of the alphabet, do not possess a constant value and for the most part people are not as conscious of their own peculiarities of pronunciation as are those who listen to them. Hence the attempt to secure phonetic spelling is destined only to make confusion, destroying the safe ground of existing conventions and substituting forms that are inconsistent among themselves and contradictory to their origin. We shall have an uneasy compromise between custom and phonetics. Neither Professor Skeat nor Dr. Murray, neither the wealth of a steel magnate nor the approval of a high executive, will succeed in dictating usage. Thank Heaven, matters of such world-wide importance cannot be settled except by world-wide agreement and when the Public Printer sets the example, we can afford to be patient. "It is to laugh." Who ever reads what he prints? It is true we mining engineers read a great deal of valuable matter emanating from the Geological Survey, at Washington, but this is all edited by cultured men in whom we repose confidence that they will not give way to a vulgar temptation. As for the rest, the political and industrial documents of the Public Printer reach the average citizen only through the medium of his newspaper, the editor of which edits it to conform with an established style. In this connection we note that one of the first to fall in with the President's order—or suggestion—was a New York attorney, who, in sending specifications to the Patent Office, adopted the 'reformed spelling.' There is exquisite humor in the notion of the Patent Office setting any sort of example, it being notorious that for curious spelling, bad grammar, and confused language, the records of the Patent Office are distinguished by a lonely splendor. Spelling must abide by the arbitrament of usage, and the printed matter most used is that of the newspaper. It is a fact, unfortunate in some cases, that among grown men ten newspapers are read for each book, and in many cases business men read the papers only. When the *London Times*, the *New York Evening Post*, the *Melbourne Argus*, the *Montreal Star*, and other representative newspapers adopt the new spelling, then the MINING AND SCIENTIFIC PRESS will accept the inevitable. Until then we are content to see changes come slowly, without fuss and without confusion.

By the Way.

In a recent address at the Commencement of Stanford University, Mr. Benjamin Ide Wheeler, president of the University of California, said:

The definition of language as voice expressive of thought is doubly inadequate. In the first place, it is far less a means of expression than a vehicle of communication. Historically it takes its form almost entirely, not from the prompting to express what is within one, but from the suggestions of hearing as to what will be intelligible to others. It is a means of communication; it always takes into account the other man; it is pre-eminently a social instrument. In the second place, it is, in modern civilized society, addressed more to the eye than to the ear. Most of us read every day more language than we hear, even if we limit our reading to newspapers and text-books, but if we turn to the higher intellectual life, there can be no doubt that our acquaintance with the larger range of powers and possibilities in language is determined immeasurably more by reading than by hearing.

The modern State is national by virtue, not of unity of blood or faith, but pre-eminently by virtue of unity in the medium of intercourse, primarily by writing, secondarily by speech. Germany has one recognized standard language overlying various shrinking dialects of speech; likewise France, Italy, Holland, Spain. Norway is held aloof from Sweden by a distinct standard of Scandinavian speech, and is turned toward Denmark. Austria-Hungary fails of nationality from lack of a common idiom.

I come now to speak of the English language. This has made more than a nation and more than an empire. The one instance in history of a single language serving two great empires; it has dedicated a broad region belting the globe to free intercourse and equality before the law. Historically it is a dialect of the English Midlands elevated by natural processes to supremacy above its colleagues and gradually extended with the spread of the English empire throughout the world, being enriched and cosmopolitanized, lifted out of its provincialism, and fitted for its broader tasks by materials absorbed from multifold sources, and being simplified in its structure and mechanism by submitting to use in the mouths of men of various minds and various tongues.

The many inconsistencies that are frozen into the mass of English orthography are undoubtedly a barrier to the acquisition of the language now extending itself as a common vehicle of intercourse beyond its natural habitat. In the inevitable discussion of its reform, however, a sober consideration of all that is involved must warn against the rash imperiling through shallow judgment of the greater good for the lesser benefit. Here follow certain points of view:

First—Uniformity in the written language throughout its entire territory in any given period, as the present, is a prime demand of civilized intercourse.

Second—The establishment for the United States of a standard of written English different from that recognized elsewhere in the English-speaking territory is an isolating and divisive movement promising loss and waste to intercourse and culture, and introducing consciousness of contrariety where the opposite is desired. The needless irritation caused by the minor differences already existing points ominously to what would result from greater.

Third—The English language is not the property of the people of the United States, still less its Government; it is a precious possession of the English-speaking world, and the moral authority to interfere with its regulation

must arise out of the entire body and not from a segment thereof.

Fourth—Every person who is born to the use of the language inherits thereby a definite advantage in the world for intellectual gain, for influence and effectiveness, yes, even for commercial success, by very reason of its extension of use in uniformity of standard. This inherited advantage constitutes a vested interest and must not be trifled with.

Fifth—Any radical change, such as for instance would be involved in phonetic writing, would have the effect of cutting us off from the language of Shakespeare and the English Bible, making of this a semi-foreign idiom, to be acquired by special study. Indeed, our entire present library collections of English books would be placed beyond the reach of the ordinary reader, and be as Dutch to his eyes. The bond uniting all the product of the language from the Elizabethan period to the present day creates a very precious heritage for every speaker of the English tongue.

Sixth—The adoption of a phonetic writing, it should furthermore be remembered, would involve initiation of the various dialectal forms of the spoken language—all of which is highly interesting to phonologists, but to the plain reader anathema.

Seventh—Print is addressed to the eye, and the reader's eye, taking in whole words or even the composite form of whole phrases in rapid glance is disturbed and hindered by abnormal forms of spelling.

Eighth—The proposal gradually to introduce through the co-operation of volunteers a certain number of new spellings, and then, when these are well under way, presumably certain others, seems to promise an era of ghastly confusion in printing offices and in private orthography and heterography, as well as much irritation to readers' eyes and spirits.

Ninth—The list of three hundred words proposed by the Simplified Spelling Board is a somewhat haphazard collection following no very clear principle of selection. One hundred and fifty-seven of them, such as *color* for *colour*, are already in their docked form familiar to American usage. The remainder seem to owe their inclusion in the list to their having been misspelled a number of times in English literature; thus, the *y* is tabooed in *pigmy* (for *pygmy*) not in *synonym*; the older spelling is resumed in *rime* (for *rhyme*), but not in *gest* for *quest*, or *tung* for *tongue*. There is no excuse, however, for *thru* (for *through*) from any point of view. The symbol *u* carries generally in English the value *ru* (in *use*) or *u* (in *but*); only very rarely, as in *rural*, *rumor*, has it the value *oo*. *Thru* has not even the authority of error.

The interests here involved are too serious to be treated craftily, or on the principle of the entering wedge. If these are all the changes to be made, they lack system, and are unworthy. If more are to be exacted, let us know what we are doing. The English tongue is our priceless heritage whereby we as a people and as individuals are made members of the widest community of intelligence and freedom in the records of mankind and sharers of the amplest traditions of vigor, integrity, and self-government, and it behooves us to deal considerably with it, and keep it in honor. This possession furthermore we hold in joint title with many peoples in many lands, and we may not ask for the portion of goods that is ours without injuring the rights of others and likewise impairing our own estate and the inheritance of our children. In the jealous keepership of our children and our children's children, the tongue in which our fathers spoke, the freedom of the individual man shall become with the unfolding of the years the chief instrument of unity and peace among all men.

Copper Mining in Ireland.—Interesting Revival of an Old Industry.—

Good News from Cornwall.—Annual Meeting of Camp Bird.—

A Fine Showing for Four Years' Work.—Milling at the Dolores.

Tube-Mill Practice.—Record Output from the Transvaal Fails to Move the Share Market.

A recent issue of the *Irish Times* contains some interesting particulars concerning the antiquity and resuscitation of the copper mining industry in Bonmahon, County Waterford. Smith, in his 'History of Waterford,' calls attention to a manuscript of the Bishop of Clogher in Trinity College, in which mention is made of valuable mines in the neighborhood of Annestown or Bonmahon in the sixteenth century. The mines were worked in 1745 by a syndicate which had obtained a 31-years' lease, conditional on rendering an eighth-part of all the ore obtained to Lord Ranelagh. According to Smith, "the works were carried on with great spirit and tolerable success; but a want of union among the members of the company, injudicious arrangements, and, above all, unfaithful men as managers, checked the progress of the undertaking, and it was at length abandoned." Redmond, in his 'South-East of Ireland,' continues the story as regards more recent times, and tells us that The Mining Company of Ireland was formed in 1824, with a capital of \$500,000, of which, roughly speaking, about quarter of the amount was paid up. The success of that portion of the undertaking relating to the working of the copper mines was so great at first that the shareholders received in dividends more than twice the value of their shares. But as time rolled on, competition so increased that the value of copper fell, and as it was found unprofitable to work the mines they were closed down in the year 1870. Coming to more modern times, the two companies which early in the present year took in hand the Bonmahon mining work are being rewarded with success. A considerable amount of rich copper ore has already been won and dispatched, and it is reported that a thorough survey has enabled the engineers to trace lodes inland from the sea for three and a half miles in the direction of the Comeragh mountains, and it has also been ascertained that the lodes extend beyond the town of Kilmacthomas, five or six miles away, which village is the nearest place on the railway.

The news from Cornwall is looked upon by the local correspondents as encouraging. Wheal Kitty, St. Agnes, lying to the east of West Kitty, is to be floated on the limited liability system, under the name of Wheal Kitty and Penhall's United. Several local men are said to be taking up some thousands of shares, and it would appear that no difficulty will be experienced in raising the necessary capital. In various parts of the county mining is being prosecuted with vigor. A small syndicate, operating in one shaft on the Great Consols sett at St. Agnes, has raised a valuable quantity of ore during the past few weeks, but, owing to the scarcity of water, will have to postpone stamping until the early part of the winter. At Dowgas underground work is being pushed forward, and already there are indications of riches. A plant sufficient to treat 100 tons of ore per day is being laid out. The Wheal Grenville 'bob' at Goold's Shaft which snapped in two the other day and very seriously damaged the engine and other machinery, was 29 years old, and weighed 23 tons. The split took place in the thickest part and the huge piece of iron went in two, like matchwood. Per contra the Grenville new tin-dressing plant has just been completed. Your Redruth corre-

spondent hits the mark in his reason for new capital not flowing more freely into the county. In plain language, however, there is not sufficient inducement to the promoter. People who are willing to take the trouble and risk of finding capital for such a highly speculative venture as Cornish tin mining expect due consideration. They do not see why all the money should "go into the mines" for the sole benefit of the stockholders.

At the fifth ordinary general meeting of Camp Bird Ltd. last week, Mr. A. M. Grenfell, the chairman, was able to make a good showing for the mine. According to Mr. A. C. Beatty's report the gross earnings during the last four years amounted to \$8,153,000, out of which £676,000, or 82½%, had been paid on the total capital, without counting the £115,000 now in hand, which is equal to a further 12%, that is, nearly 95% of the capital had been earned during the last four years without taking into account an estimated profit on the ore in sight of £881,000. From the balance of £115,020 will have to be provided £70,000 for the reconstruction, leaving an undivided surplus of about £45,000. It is expected that crushing will be resumed before December 1, the date originally estimated by the engineers. Mr. Beatty and the Chairman came to the conclusion that, provided it did no harm to the future working of the mine, it would be advisable to start by attacking some of the richer stopes and put high-grade ore through the mill, thereby making larger profits than the average, and so recover the company's financial position as soon as possible, provided that Mr. W. J. Cox, the manager, would adopt such a policy and that it can be carried out without in any way injuring the mine. It is hoped to resume dividend payments soon after the first period of crushing. In passing the usual vote of thanks to the staff in America and their assistants, special reference was made to the services of Mr. Thomas Woods during the fire at the mill.

Dolores circular just issued brings up the information about the mine to the end of July. The tonnage milled for that month is reported as 1,350 tons. Of this total 368 tons came from the mine for amalgamation. The bulk of the remainder came from the dump for cyaniding, while some 200 tons odd of old tailing were re-treated. The total production as called for by the assays is estimated at about \$49,500 for the month. As pointed out in the May report, a part of this extraction, some \$7,500, would remain in the cyanide plant, a condition which is not expected to be obviated until after August. From the \$42,000 value of the bullion recovered, a profit of \$22,000 is reported for July, after deduction of \$20,000 for operating expenses. In explanation of the milling not having reached the full running capacity Mr. John B. Farish reports as follows:—"The principal delays in the mill have been caused by the continual choking of the cone-classifiers. These were designed and built according to the best possible usage, but the ore of the Dolores seems to require in this respect, and in the tube-mill a different arrangement from that of our practice. We are now installing a mechanical classifier which we hope to have running in September, and which I think will give us better results than we have been able to obtain with the most improved cone classifiers. The tube-mill has proved a disappointment in one way. The engineers, and our own experience, indicated that it would have ample capacity to handle all of the pulp from the 15 stamps. This was apparently confirmed by the tests made at the Creston Colorado; but the tube-mill erected at the Dolores was in one way an experiment, being the first sectional one ever built. It has performed its work excellently, but has been unable to slime the total pulp produced by the 15 stamps. Our crushing facilities are ample to take care of more ore than the 50 tons daily of

crude material for which the mill was designed, but as indicated above, the tube-mill and the cone-classifiers have not yet been able to take care of the product turned out by the crushing department. To remedy this we shall either install an additional tube-mill or grinding pans for sliming the material. I have already pointed out that one of the most important features in opening and equipping a new property has been satisfactorily solved, that is, the treatment of the ore. Upon the completion of this additional machinery, namely, concentrators, mechanical classifiers, an additional tube-mill, or grinding pans, and possibly an additional agitating-tank, the mill will have the capacity originally intended—1,500 tons per month—or what is more probable a capacity of over 1,600 and, possibly, 1,700 tons per month of crude mine ore." The development of the mine appears to be proceeding satisfactorily although slowly, owing to shortage of skilled labor. The main shaft has almost reached the depth of 550 ft., at which point the fourth level will be extended. In Mr. Parish's opinion the opening of the fourth level at the above-mentioned station in such ore as is shown on the third level, and with a width corresponding to that shown in the drift and cross-cut No. 1 will place in sight an additional tonnage and value of ore almost or quite equal to the amount figured by the experts as being in sight in the mine, at the time of the purchase of the property. Meantime he believes that a conservative estimate of the ore already opened in connection with the third level will equal the amount extracted and treated during the time the mill has been in operation; in other words, the ore reserves above the third level were not less on July 1 than they were at the time the property was taken over.

Another record output of gold in the Transvaal—509,115 oz. for August—has not served to lift the market for Kaffir shares out of the rut into which it again fell after the recovery during the holidays. A correspondent of the *Spectator* endeavors to find a new terror for South Africa in the possibility of the initiation of the black man by the Chinese coolies into the mysteries of the secret societies so much in vogue amongst the Asiatics. So far such knowledge, on the dark continent, is believed to be limited to West Africans.

Denver, Colorado.

Milling Methods at Idaho Springs.—The Yak Tunnel and its Increasing Output.—Dredging at Breckenridge.—Confused Politics in Colorado.

After several years of experimental work at Idaho Springs it seems probable that a large custom mill will be erected. The experimental work has been done by several different parties. Lafayette Hanchett, manager of the Newhouse tunnel, was one of the pioneers. He proved that many improvements could be made, but went to the Cactus mine in Utah before his idea for a large mill had been carried out. Then William E. Renshaw, manager of the Gem Consolidated, took up the investigation and built a mill of 40 stamps on the most approved modern lines. This mill did better work than anything built before, but still it did not quite solve the problem. Then Tanner & Anderson built a little mill and added a cyanide department. They showed that cyanide would work well on Clear Creek county ores if very carefully handled, but their unit was so small that they could not make a success of the low-grade material around Idaho Springs and turned their plant over to the treatment of Empire ores, where they secured contracts for higher grade stuff. There seems to be an immense tonnage of ore in the immediate vicinity of Idaho Springs that is generally spoken of as \$5 stuff. It probably goes a little less. All

well-informed men agree that the tonnage is enormous. Most of this low-grade ore has been developed while extracting bodies of higher grade ore, so that the cost of development need not be charged against it. The problem then is, to stope, haul and mill this stuff at a profit. Henry B. Clifford & Co., of New York, are said to be heavily interested in the Gem Consolidated and they have under consideration the plan of building a very large mill at Idaho Springs for the Gem ores and for custom work also. They have studied carefully the results already obtained locally, and have conducted experiments independently. It is said at Idaho Springs that plans are now being prepared for a mill of 1,000 tons daily capacity.

Another mine has become tributary to the Yak tunnel at Leadville. This adit is fast becoming a great artery of ore production. Electric haulage enables the ore-cars to rush along the adit at express train speed every few minutes. I believe each car holds three tons and nine to twelve cars go out in each train. The outer terminal is as busy as a city freight-yard. Ores from a dozen different workings are assorted and dumped with business-like system. Here is a car of high-grade carbonate for one shipment, there a car of low-grade iron for another shipment, here a car of zinc and lead for one part of the big mill, and there a car of low-grade galena for another department. Truly, as one stands at the portal of the great adit, the bug-bear of mining, that of finding the ore, seems to have been entirely eliminated from the problem and the only question seems to be that of systematically handling the product. The owners of the Louisville, Hanifren & Reynolds have arranged a connection with the Yak tunnel on their 600-ft. level. The shaft is 950 ft. deep. The water and ore will be raised from the lower levels to the adit level by electric power. The Yak tunnel put down two diamond-drill holes which revealed a body of iron sulphide 40 ft. thick on the lower contact extending into Louisville ground. There are large bodies of zinc ore already exposed in the old stopes of the Louisville and this ore will be taken out at once.

At Breckenridge, Ben Stanley Revett's dredge, the Reliance, which is working a small acreage in the midst of the big French Creek placer, is on the home stretch of a very successful run. The dredge did not get well started last season before it had to shut down. This year everything seems to have been favorable. There was plenty of water and good rich ground was encountered. The manager, Mr. McDonald, late of Oroville is enthusiastic and says the enterprise is an unqualified success.

Denver politicians were given a shock on September 18 by Philip B. Stewart, who resigned the nomination for governor. Politicians do not generally resign nominations, particularly when their party looks like the winner. Stewart does not like his running mate, Judge Gabbert, who is nominated for the Supreme bench. Gabbert took a prominent part in the cases arising from the late Cripple Creek labor troubles, and was so emphatically on the side of law and order that he got the name of being an enemy to organized labor. It would have been good policy to have left Gabbert off the ticket, but the way tickets have been cut to pieces in this State the last few years ought to have shown Stewart that his running mates could neither help him nor hurt him to any great extent. Henry A. Buchtel, chancellor of Denver University, has been nominated to take Mr. Stewart's place on the Republican ticket. Judge Ben Lindsey announces he is going to go it alone for the governorship. The judge has made himself famous by his Juvenile Court work. Many men will vote for the judge, because he is a good, honorable man, but people who know him think nature built him for a Juvenile Court and not for a governor.

Butte, Montana.

Butte Men Operating in California.—*North Butte Increasing Output.*—*Important Discovery in the Ophir.*—*Good Ore in the Simons Mine of the East Butte Co.*—*The Lexington is Being Pumped.*—*Taxes Paid by the Amalgamated Company.*—*Repairs to Several Shafts Curtail the Output.*

The organization of the Furnace Creek Extension Mining Co. has been perfected in Butte. It has been incorporated with a capital stock of \$5,000,000, divided into 1,000,000 shares of the par value of \$5 per share. Officers have been elected as follows: President, George W. Irvin; vice-president, John MacGinniss; treasurer, R. B. Nuckolls; secretary, H. F. Collins; board of directors, in addition to the three officers named, J. D. Slemons, A. J. Campbell, and Fayette Harrington. The company has 11 copper claims in Inyo county, California, adjoining the property of the Patsey Clark Co., and a few weeks ago a large vein of copper ore was cut in the course of exploratory work.

The North Butte Co. is at present shipping an average of 1,000 tons of ore per day to the Washoe smelter at Anaconda, and is employing 700 men. The company each month uses 650,000 ft. of lumber, but the amount will be increased to about 1,000,000 ft. within a short time. Since it began operations the North Butte Co. has paid \$57,618 for machinery. It paid out for labor during the six months ending June 30, \$383,656, but the payroll has been increasing since then, and in August it amounted to \$70,000.—The Red Metal Co., a subsidiary of the Butte Coalition, produced 1,500 tons of ore daily until the first of September, when one of its big producing mines, the Minnie Healey, was shut down to permit repairs to be made to the shaft. Since then the company has been shipping about 1,100 tons per day. The company employs 988 men.—The Butte & Bacon Co., which is developing a group of copper properties in the new district north of Butte, has reached a depth of 400 ft. with the shafts on the Belinda and Calumet claims. The Colleen Bawn shaft, which is on the principal claim of the company, is in bad ground and the company has had a great deal of difficulty with it, progress in sinking being slow.

A large body of silver and gold ore has been discovered on the 200-ft. level, 500 ft. east of the shaft, in the Ophir mine, owned by the newly organized Butte Central & Boston Copper corporation. A cross-cut is 40 ft. in the orebody, all of which is shipping ore, assays showing 60 oz. silver and \$4 in gold per ton. The vein is 60 ft. wide at that point and the indications are that the orebody fills the vein. It is apparently one of the largest silver deposits ever discovered in the Butte district. About 100 ft. east of the shaft on the 300-ft. level a bunch of ore was discovered a few weeks ago which carries a good percentage of copper, and the opinion of Manager McConnell is that both discoveries belong to the same orebody, and that the vein will be found to turn into copper at greater depth. The mine is being worked by lessees. The company's work has been confined to sinking the shaft, which has been sunk from a depth of 300 to 500 ft. A station, 16 by 30 ft. and 10 ft. high, has been put in at the 300-ft. level.

The East Butte Mining Co. has resumed work on the cross-cut being ran north and south from the 400-ft. station, and it is expected that some of the known veins will be encountered within a month. Work was stopped some time ago because of the proximity to the veins and the fear of a flood of water, which the company was not at the time prepared to handle. A large pump has been installed at the 400-ft. station. Lessees working the Simons mine of the East Butte group are extracting some

of the richest copper ore mined in the Butte district, assaying 20% copper. James W. Neill, consulting engineer to the company, has been in Butte several weeks inspecting the work and exploration being done, and has made a report, of a very encouraging nature, to the stockholders. He says one of the biggest sources of revenue is the precipitating plant built on the company's ground by lessees who are paying 25% royalty on the copper recovered from the old Parrot smelter tailing which covers about eight acres of East Butte ground to a depth of 5 to 25 ft. The plant, which was built at a cost of \$30,000, will revert to the company at the expiration of five years, after which it will be operated by the company itself. Mr. Neill says it will earn a big profit for at least 20 years. The company also expects to be mining ore on its own account within a few months.

La France Co. has lowered the water in the old Lexington mine to the 1,000-ft. station, which leaves 450 ft. more to be pumped out. As the workings are extensive, the work of unwatering will be slow. It will be several months before the mine is completely cleared.—The Davis-Daly Estates Co. is now sinking on the Silver King, Mt. Moriah, and Colorado claims, and it is announced that exploratory work will also be done through the Smokehouse shaft, which is situated at the corner of Broadway and Wyoming streets. It has been the intention of the company to use the Smokehouse only for purpose of ventilation, but recently workmen engaged in excavating for a cellar about 150 ft. west of the Smokehouse shaft cut a large copper vein, which prompted the company to explore the ground thoroughly through the Smokehouse. The shaft is 500 ft. deep and Manager Palmer expects to hoist ore from it within two months.

—The Butte-Milwaukee Co. is raising some ore from the 250-ft. level of the Pollock mine, and will go after the vein also on the 350-ft. level. The Pollock is equipped with a fine hoisting plant.—The East Butte Extension Mining Co. is shipping about 40 tons of ore per day from its four producing shafts. The ore assays 7% copper.

The Amalgamated Copper Co. owns property in 16 counties of Montana and pays taxes on a total assessed valuation of \$26,911,857. The Washoe smelter, built at a cost of \$9,500,000, is assessed for only \$3,100,000, and all of the company's properties are assessed at the same ratio to their actual value. Its greatest assets are, of course, its mines, which are assessed and taxed only at \$5 per acre, but the company pays taxes on the net proceeds of the mines. The Amalgamated pays one-third of all the taxes collected in Silver Bow (Butte) county, and one-half of all taxes in Deer Lodge (Anaconda) county. The company's mines are situated in Butte and its smelter at Anaconda.—A report circulated in the East and telegraphed from Boston to the effect that John D. Ryan and Thomas F. Cole are to be added to the board of directors of the Greene Consolidated Co. is emphatically denied by Mr. Ryan. "I am not even a stockholder in the Greene Consolidated," he said. "So far as I am concerned there is absolutely no truth in the rumor. I feel certain that Mr. Cole has no intention of going on the board or I would have heard of it."

The Mountain Consolidated mine of the Anaconda Co., the Clear Grit of the Washoe Co., the West Colusa of the Boston & Montana Co. and the Minnie Healey of the Red Metals Co. are still closed and will not be reopened until late in October. The shafts of all except the Clear Grit are being repaired, and the Clear Grit had to be closed because it was mined through the Mountain Consolidated. The suspension of the four mines reduced the daily output of the Butte district about 1,200 tons daily during September. The Minnie Healey will use the old shaft, when repaired, only temporarily, as it is unsafe. A new shaft

is being sunk on the Tramway by the Red Metals and Butte & Boston companies, and eventually the Minnie Healey will be worked through that property. The new shaft on the Leonard, a Boston & Montana property, has been opened to a depth of 1,200 ft. and is ready for use, but the surface equipment has not yet been completed. —The shaft on the Butte & London property, the Greendale, is 620 ft. deep. Nothing has yet been encountered to indicate the close proximity of a vein. The shaft may be sunk to a depth of 1,500 ft. before any cross-cutting is done. —The Farrell Copper Mining Co. has elected the following officers: President, W. C. Lewis; vice-president, Carlton H. Hand; treasurer, J. D. Slemmons; secretary, Proctor Barclay. The company has secured title to 17 acres of ground in East Butte. It is capitalized for 400,000 shares at \$2.50 each. The company will work the property through the shaft of the Alliance Copper Mining Co. —Work has been suspended on the property of the Butte Hill Copper Co., because of a hitch in the negotiations for floating the company. Some St. Louis capitalists are willing to put up the money to develop the property, but not on the terms proposed by the promoters.

Toronto, Canada.

A Useful Bequest.—Dredging on the Yukon.—The Laurentian Mine.

The will of the late Aeneas McCharles, of Sudbury, Ont., bequeaths \$10,000 to the University of Toronto as a fund, the interest from which is to be given from time to time: (1) To any Canadian inventing any new and improved process for the treatment of ores, of practical value; (2) for any important discovery or device by a Canadian for lessening the danger in connection with the use of electricity for power and light; or (3) for any marked public distinction achieved by any Canadian in scientific research in any practical line.

F. E. Folsom, of Toronto, who has recently returned from the Yukon, where he is interested largely in mining properties, states that dredge mining is proving very successful in handling the gravel of the rivers. A dredge is at work about half a mile up the mouth of the Klondike, with buckets of over 5 cu. ft. capacity, turning over 3,500 yd. of gravel per day. The ground is so rich that a new dredge, with buckets of 15-ft. capacity and equal in size to the giant dredge at Folsom, Cal., will shortly be installed. It is proposed in the near future to substitute electric power for steam in the operation of the dredges.

When sinking the main shaft at the Columbus mine, Cobalt, a cross-vein running at right angles from the main vein was struck at 52 ft., which was found to improve rapidly down to the 60-ft. level. The management is installing a complete steam-power plant, consisting of boiler, steam drills, pumps, and air blower. —John Ernst, of Ernst & Gowman, who published a map of the Cobalt area, blew out his brains at Haileybury on the 15th inst. He had been lately engaged in developing three claims, but his applications for location were thrown out by the mining inspector and he had suffered from despondency for some days. His home was in Detroit.

Anthony Blum, principal owner of the Laurentian gold mine in the Manitou Lake district, states that a million dollars worth of ore has already been blocked out. The working force has been increased by a large number of Finlanders. It is proposed to have a thorough examination of the mine made this fall by a prominent American mining engineer with a view of more extended development operations. —The will of the late Thomas G. Blackstock, of Toronto, has been entered for probate, showing a net estate of \$350,000.

Mexico.

Meeting of the Geological Congress.—Its Truly International Character.—Lack of Discussion, Owing to Entertainments.—Defeats Purpose of a Scientific Gathering.—A Brilliant Affair.

The tenth session of the *Congres Géologique International*, which was held in the City of Mexico, September 8 to 14, was in many regards a notable meeting. The attendance was unusually large, over 600 members being enrolled. About one-third of this number was in actual attendance. The Congress was truly international in make-up, all the continents and most countries being represented. Mexico naturally furnished the largest delegation, followed in turn by the United States and the German Empire. Canada, France, Austria, Great Britain, and Russia were fairly represented, while one or two were present from Australia, Japan, the Philippines, Italy, Spain, Sweden, Hungary, and a number of other countries.

The social features of the Congress were particularly well carried out, the hospitality of the Mexican Government and citizens being so lavish as to be almost embarrassing.

Ten sessions were held for the reading of papers, but the variety of subjects proposed for discussion, and the number of titles submitted left practically no time for the active interchange of ideas and criticism which ought to have been one of the features of the occasion. This difficulty is one of growing importance in all scientific and technical meetings, and it is hoped that some way may be found to remedy it in future congresses.

Since the work for which the *Congres Géologique* was first called together has now been largely accomplished, the reading of papers and scientific discussions must in the future be given more attention unless the organization be devoted wholly to social purposes. There is evidence that it has already made dangerous progress in the latter direction. The elaborate and attractive excursions and banquets, which it has become customary to offer gratuitously or at nominal charge, attract the dilettante more than the worker and the very large numbers present defeat the main purpose of the gathering. The local committee in each case has no really adequate means of determining who among the applicants are worthy, and has customarily given all comers the benefit of doubt. A result is the enrollment as members of a large number whose chief qualifications are the possession of a vigorous appetite, an insatiable thirst and an ever present kodak.

The present Congress was no worse than several of its predecessors, if as bad, and yet there were present an English undergraduate who is not even studying geology, a Russian botanist, the secretary of an obscure natural history society in New York, and several others equally out of place. The presence of many of these was a simple abuse of the generous hospitality of the Mexicans, and it is to be regretted that Americans, as well as others, were guilty. Steps already have been taken to prevent a recurrence of this at Stockholm, where the Congress of 1909 is to be held. It is hoped that means may also be found to make the sessions themselves more interesting and valuable.

In the main the Mexican Congress will be remembered as a brilliant affair, reflecting great credit on Messrs. Aguilera, Ordoñez, and other members of the committee who contributed so much to its success. The excursions before and after the Congress were so arranged as to afford the visitors a generous sight of the mines and mining districts of the Republic, and from El Paso on the north to Tehuantepec on the south, there was a cordial welcome to all—Americans included.

Bisbee, Arizona.

Discoveries in the Huachuca Mountains.—Important Transfer Made.—Compressed-Air System at the Copper Queen.—Increased Output From the Shattuck-Arizona.—Encouraging Reports From Tombstone.

During the past week ore has been found at the Butte & Arizona property in the Huachuca mountains, and the Warren Realty & Development Co. is reported to have been taken over by the Calumet & Arizona Co. Formerly the Huachuca mountain mining district has not been looked upon favorably on account of the unreliability of a number of companies which operated there, but within the past year or two a number of responsible companies have entered the district, and good results have been obtained. The Butte & Arizona Co. opened up a rich sulphide orebody on Wednesday night. About two months and a half ago this company, composed of men prominent in the Amalgamated Copper Co., purchased the property. They immediately put a force of men to work, and decided to drive an adit, to find out in the shortest possible space of time if the property had any merit. This adit had been driven about 350 ft., when the face showed a full front of sulphide ore. A test was made, and it was found that the ore carried nearly 27% copper. Up to the present the drift is still in the same formation. The place for sinking the shaft has not been selected as yet, but the management states that no time will be lost in opening up the property.

It was rumored in Bisbee several days ago that the Warren Realty & Development Co. had been absorbed by the Calumet & Arizona. L. W. Powell, manager of the Cole interests in this district, left the city for Duluth on Wednesday afternoon, and it is stated on reliable authority that he will meet Thomas F. Cole and Hoval A. Smith there and arrange the details of the transfer. It is known that a large body of ore has been encountered on the Warren property, but the management will not give any details to the public. It is also stated that the American-Saginaw Co. will be absorbed by the Calumet & Arizona, but it is not likely that this will be consummated before the next meeting of the American-Saginaw directors.

A number of the delegates to the International Geological Congress, which was held at the City of Mexico, visited the mines of Bisbee, when returning from Mexico.—On the Copper Queen property the new Nordberg compressor is being erected at the Lowell shaft. At the present time compressed-air mains are being run from the Gardiner to the Czar shaft, to connect with that system, and as soon as this connection is made the entire air system of the Copper Queen mines will form a complete circuit. The steel work on the new machine-shop is practically completed, and the carpenters will be put to work this week. The raising of the new Holbrook shaft is being rushed, and will probably be completed within the next sixty days. The new electric pump for the Czar shaft was lowered into the shaft, and the work of installing it will be commenced this week.

At the Superior & Pittsburg properties everything is about the same as usual.—At the Calumet & Arizona most of the attention is being directed to the perfecting of the hoisting and pumping machinery.—At the Shattuck-Arizona the output was increased this week from 175 tons to 200, and from this time on the output will be increased steadily. The tramway is working satisfactorily. The new assay-office is being erected and will probably be finished within a couple of weeks. The new Allis-Chalmers hoist is expected to arrive this week, and as soon as it is placed in position the engine-house will be built and the Junction hoist returned to the owners. On

the 600-ft. level the drift is showing up very well in a limestone formation. On the 700 two new stopes are being worked; one sulphide and the other oxide. On the 800-ft. level a new sulphide orebody was encountered on Friday. Both of the raises from the 800 to the 700 are in oxidized ore, and are being stoped.

At the Denn-Arizona, the drift on the 1,000-ft. level is showing up very well in manganese and iron. The cross-cut that is being driven from the drift to the diamond-drill bore is progressing rapidly, with no material change from the formation in the drift. The new Prescott pump is expected to arrive this week, and will be installed at once. — Reports from Tombstone are to the effect that since the new boilers were placed in position the water has been taken care of, making sinking of the shafts possible. At the present time 4,000,000 gal. water are being pumped every 24 hours. The main shaft will be sunk to the 1,000-ft. level, and a new pump, which is now on the ground, will be installed there. At the mill everything is running smoothly, 40 stamps dropping continuously, and crushing about 200 tons of ore per day. A tramway has been built from the tailing bed to the upper side of the mill, where the ore is hoisted into the bins.

Salt Lake, Utah.

Economic Mining at Mercur.—News from Tintic.—New Sampling Works at Salt Lake.—The Interstate Commerce Commission Investigating Railroad Rates.—Important Testimony.

The annual report of the Consolidated Mercur Gold Mines Co., operating at Mercur, for the fiscal year ending June 30, has just been issued and shows net earnings of \$112,787, out of which were paid four quarterly dividends of \$25,000 each; also \$8,104 for construction, while the surplus at the end of the year amounted to about \$126,000. The average of the ore treated was \$3.76 per ton, which is an average of 19c. lower than last year, due to the handling of 75,000 tons from the Magazine vein valued at about \$2.50 per ton. An average of 830 tons per day was mined at a cost of \$1.41 per ton, while the mill costs showed an average of \$1.07 per ton, making the total expense of mining and milling \$2.48 per ton. Wherever practicable the management has been driving by contract, or piece work, and all such contracts have averaged \$3.27 per shift, while miners have received from \$2.50 to \$2.75 per day. The mill tailing ran lower than last year; in September 1905 it was the highest, namely, \$1.06; and in February 1906, it was lowest, 88c.; the average for the twelve months being \$0.956 per ton.

The machine-men at the Grand Central and Victoria mines, in the Tintic district, have been granted an increase in wages of 25c. per day. They now get \$3.25.—The shaft at the West Mammoth mine is down 300 ft.—An effort is being made to effect a permanent organization among the mine owners and operators of the Tintic mining district. The interests of that camp have been acting in concert for some time in working with the railroads to grant a reduction in freight-rates to the Salt Lake smelters.

An important strike has been made on the 1,000-ft. level of the New Stockton mine at Stockton. Copper is appearing in the Leopard vein, indicating that as depth is attained, that metal will cut an important figure. — Last week's ore and bullion settlements aggregated over \$500,000, while during the same period on the Salt Lake Stock & Mining Exchange, 442,500 shares were sold, for which was paid \$213,997. — Excavations have been made for a new sampling mill near Salt Lake, the same to be built by the Taylor & Brunton Sampling Co. — The plan of the Continental Mines & Smelters Corpora-

tion, which acquired a right-of-way from the Rio Grande Western railway, to build a railroad into the camp of Alta, seems to have fallen through.

The gasoline engine at the hoist of the Magnolia St. Louis mine at Park City is being replaced by a larger steam-plant.—The mill at the Cactus mine of the Newhouse Mines & Smelters Co. in Beaver county is giving treatment to 800 tons of ore daily. Forty per cent of this tonnage is mined through the square-set system and the balance by the steam-shovel or glory-hole method.—Encouraging reports have come from the Sevier Consolidated mine in the Gold Mountain district, which the management has announced is now self-sustaining. An additional conical classifier is being added to the mill, which will bring the plant up to its capacity of 125 tons per day. Conditions in the mine are most satisfactory. Some exceptionally high-grade goldore for this district has been recently developed.

The Interstate Commerce Commission has begun an investigation at Salt Lake. The hearing started on the 24th inst. and up to this time it has been centered on the alleged discriminations of the Harriman railroads in favor of the three big coal companies of southwestern Wyoming. Many witnesses have been subpoenaed and indications are that some sensational testimony will be brought out and that the railroad management will be placed in an unfavorable light, as well as those who have directed the management of the coal mining concerns. The coal companies involved thus far are the Kemmerer Coal Co., Diamond Coal & Coke Co., and Union Pacific Coal Co. An attempt is being made not only to show that these coal mining concerns have acquired vast areas of coal-land by fraud, but that the transportation companies have discriminated against certain dealers in Salt Lake and elsewhere by a secret system of rebates and other means. One Salt Lake dealer, D. J. Sharp, who had been in the retail business in Salt Lake for a number of years, gave some interesting testimony to the effect that because he had advertised to sell coal at \$1.75 per ton during the past summer, giving the customer the benefit of the summer storage rate, amounting to 50c. per ton, he was forced out of business by the railroads refusing to haul coal consigned to him. The investigation will not be confined to the Wyoming field alone, but the Gould lines and the closely allied coal companies are charged with offences equally grave. The hearing will probably not be completed for some time.

Cripple Creek, Colorado.

Steady Output from El Paso.—The Lonaconing Doing Well.—Transfer of United Gold Mines to Golden Cycle Co.—The Christmas Making Steady Shipments.—Rich Ore in the South Dante.—Telluride Mill Rebuilt for Cyanide Work.

An average of two cars of ore per day has been shipped this month by the El Paso Gold Mining Co., on Beacon hill. The ore runs about \$10 as shipped and is obtained from the upper four levels of the mine. This steady production accounts partly for the rise in the value of the shares which has taken place recently.—Carlton and associates, leasing on the Lonaconing mine, situated on the west slope of Beacon hill, have shipped eight cars of ore this month, which have averaged better than 1½ oz. per ton. Work is being carried on by machine-drilling both north and south of the shaft at a depth of 300 ft., the orebody averaging four feet wide.

The most important news of late is the transfer of the properties of the United Gold Mines Co., formerly controlled by the Woods Investment Co., to the Golden Cycle Gold Mining Co. The purchase price is said to be in the neighborhood of \$350,000. These properties, which in-

clude the Wild Horse, Deadwood, Damon, Hardwood, Trachyte, Silver Tip, and the W. P. H., will be extensively worked by the Golden Cycle Co., which is one of the most progressive in the district. It is said that the above properties, and those under lease to the Western Investment Co., will be run in conjunction, as several of the latter company's officials are also directors of the Golden Cycle Company.

Low-grade ore is being shipped to the Van Fleet cyanide plant near the town of Goldfield from the Carper lease on the War Eagles mine, on Bull Hill. This mill was formerly a sampler, but has lately been converted into a cyanide mill for the treatment of low-grade oxidized ores.—A lease has recently been obtained by Sherman Bell on the Apex claim, on Bull hill, belonging to the San Juan Company.

A small two-drill compressor is about to be installed on the West lease of the Free Coinage Co. near the town of Altman. Lessee West recently opened up a body of ore in the Pinto shaft of the above property.—The indebtedness of the City of Cripple Creek Gold Mining Co., amounting to approximately \$3,600, has been paid off by the shareholders, who intend to start active development work on company account. A cross-cut driven on the 450 ft. level is said to be within 40 ft. of the Abe Lincoln vein, which is expected to yield pay-ore.

The Christmas mine, under lease to Becker, Travell & Co., is yielding a car every other day of good average grade ore, which is being obtained from the 700, 800 and 900-ft. levels. Next month a five-drill compressor will be installed, owing to the La Bella lease, which has up to the present supplied the Christmas mine with air, closing down their compressor plant. When the drills become available, it is expected that a car of ore per day will be shipped.—The British American Mining Co., Ltd., leasing on the South Dante, situated on the south slope of Bull hill, is shipping ten cars of ore per month. The stope from which most of this ore is being obtained and which is approximately 60 ft. long, is showing up well in both the north and south ends. On the east wall of this stope a cross-vein 6 ft. wide was encountered, which has been followed for 15 ft., the ore averaging \$25 per ton. Good ore has also been opened up 40 ft. south from the raise on a north and south vein, the average grade here being \$30 per ton. The winze under the stope, where the main part of the work is being carried on, is down 20 ft. and the assays at the last sampling ran as high as \$150 per ton. The sinking of this winze has been stopped, as enough ore is being broken in the stope and cross-veins to keep the ore-house full. Driving from the Cody shaft, at a depth of 125-ft., on the north Granite property, on Battle mountain, by Fry, Becker & Co., is progressing in a north and west direction to the boundary lines. It is hoped that several veins, which should extend through the claim, will be cut.

The old Telluride mill at Colorado City, known now as the Golden Cycle mill, is rapidly nearing completion and will be running by November 1. This mill formerly belonged to the General Metals Co., the bromide process being used for treating the ores of the Cripple Creek district. The process was a failure, the company going bankrupt. The plant was then purchased by the Golden Cycle Gold Mining Co., who have remodeled it, installing the cyanide process under the direction of Philip Argall. The cost of this work has been in the neighborhood of \$200,000. The capacity of the mill will be approximately 250 tons per day, of which amount the Golden Cycle mine will furnish 150 tons when the improvements that are now being made on the mine shall have been completed.

Mining Summary.

ARIZONA.

(Special Correspondence).—The Storm Cloud mine in Hassayampa district, Yavapai county, is reported to have over two feet of ore worth \$60 per ton, and 1,200 tons of such ore on the dump, all of which was taken out in development work. E. E. Breeden and other parties sold seven claims in the vicinity of the Storm Cloud mine lately to a close corporation of Eastern capitalists, who will start work right away on a double-compartment shaft of 1,000 ft. The purchase price is said to be \$35,000. — Eli Hilty, of Kingman, is in Yuma looking for a lost mine, but so far has been unsuccessful in his quest. Many years ago Hilty found more than a ton of float, but could not find the vein. This float netted himself and partner several thousand dollars. With many years of experience in mining, the plucky prospector believes he can find the source of the rich float, and will put in several months making a systematic search.

Prescott, September 22.

COCHISE COUNTY.

The Tombstone Consolidated 10 by 24-ft. shaft is down 900 ft. and is being sunk as rapidly as three 8-hour shifts can do the work. It is the intention to push the work to the 1,000-ft. level before any other stations are cut or new drifts run. When that level is reached another pump will be added. At present the pumps are handling 4,000,000 gal. daily. In the shaft there are two sinking pumps that send the water to the 700-ft. level whence it is pumped to the surface by the station pumps; the pump on the 800 raises the water to the 600-ft. level, where another pump sends it to the surface. The steam-plant consists of a battery of eight marine boilers with 1,600 h.p. A new air-compressor furnishes power for the machine-drills. A tramway is being built from the big shaft to one of the old dumps so that the ore can be delivered into the ore-bins and then run through the mill. There are several thousand tons of this ore that was taken out when the shaft was sunk that can now be milled at a profit. At the mill 40 stamps are crushing 200 tons of ore per day and the cyanide plant is handling the same amount. Superintendent Tyndall is making arrangements to handle the old tailing bed. A tramway has been built to the upper side of the mill, where a small hoist will haul the loads of tailing and deliver into the ore-bins.

It is reported that the Butte & Arizona Copper Mining Co. has found rich sulphide ore after driving its adit 350 ft. in its Huachuca mountain property south of Bisbee. Thomas E. Stafford is superintendent.

COCONINO COUNTY.

The Hance Asbestos Co., of New York, will resume operations at its asbestos mines in the Grand canyon on October 1. H. H. Smith, resident manager at Grandview, says that the mines will be worked with 20 men, and the product will be shipped as rapidly as possible.

GRAHAM COUNTY.

The Gold Belt Development & Reduction Co. is shipping ore to the Shannon smelter at Clifton, as the wagon-road has been finished. About 100 tons of high-grade copper ore is on the dump and arrangements are being made to put men in the mines. Another strike has been made on the Comstock in addition to the first big strike. — The New England & Clifton Co. will start a development shaft on the Antietam mine, near Metcalf, as soon as a hoist can be installed. The company is now shipping daily 45 tons of ore to the Shannon smelter from the Old King mine. It is likely that the shipments will soon be increased to 50 tons daily.

YAVAPAI COUNTY.

The Tiger Gold Co. at Harrington has 125 men on the payroll. The company is putting in a large double-drum hoist and 200-h.p. boiler. It is continuing its double-compartment shaft, which is now down 350 ft. The 20-stamp mill has been in operation continuously for two years. The concentrate is shipped to the smelter at Humboldt. As soon as the new hoist and boiler are installed it expects to double the

milling capacity.—The Sepoy Mining Co., formerly the Apache Panther Co., is working a full crew of men and is driving the tunnel with compressed air. The company has built a wagon-road from Crown King, about two miles north, to its mine.

It is reported that a five-foot vein of good ore has been found at a depth of 250 ft. in the shaft of the Pittsburg-Jerome mine, near Jerome. — Diamond-drill holes are being sunk on the Verde Chief and the Harryhausen mines near Jerome, and late reports indicate promising results.

CALIFORNIA.

An interesting demonstration of a new explosive was made on September 21 near Berkeley, at the quarry of the Spring Construction Co. The series of tests were of the usual character, to demonstrate safety features, insensibility to shock or concussion, absence of noxious fumes, and perfect security in case of combustion. This new explosive is manufactured for shipment, in two separate compounds, designated respectively, No. 1 and No. 2. The former is a white substance, not unlike fine table-salt; the latter is of a golden yellow color. The safety features were exploited by vigorously pounding the compounds separately; and again, after the two compounds had been thoroughly mixed. In neither of these tests were there any explosions. Burning the compounds separately, and then combined, was the next test, which demonstrated that there were no noxious fumes or unpleasant odor after combustion. A pistol bullet was then fired through a cartridge containing the combined compounds, without exploding. The same powder that had been put through these tests was then placed in a paper cartridge, and successfully detonated in the open. The disruptive energy of the new explosive showed most excellent results in 'bulldozing.' A five-foot horizontal hole was charged with ten $\frac{7}{8}$ by 6-in. cartridges, and set off with most excellent shattering results. Among those in attendance who witnessed these tests were Prof. W. B. Rising of the University of California, F. F. Thomas of the Gwin mine, Louis T. Wright of the Mountain Copper Co., T. A. Rickard of the MINING AND SCIENTIFIC PRESS, R. Gilman Brown of San Francisco, Louis Rosenfeld of the Eagle-Shawmut Mining Co., M. J. McDonald of the Keystone Consolidated Mining Co., Wm. Sharwood of the Soulsby mine, E. T. Blake of the Oakland Paving Co., W. H. Shockley and B. F. Edwards of Tonopah, Wm. Schmidt, John E. Porter, and John Brown of the Spring Construction Co., W. P. Doyle, F. L. Little, John Mason, the inventor of the new powder, and A. B. Murray of the American Safety Powder Co. The opinion of all those present was most favorable, and the demonstration was satisfactory in every way; it was given under the direction of George W. Myers, of Berkeley, the contracting agent.

KERN COUNTY.

(Special Correspondence).—The Kern County Consolidated Gold Mines, Ltd., has bought the Old Piute mine from H. B. Chase and associates, and has commenced to develop the property on a large scale. A new hoist, air-compressor, sawmill, etc., have been installed. Twenty men are working, and more will be added as fast as they can be obtained. The purpose of the company—composed mainly of French stockholders—is to enlarge their scope by acquiring other worthy properties in this district. F. W. D. Gwynne is manager for the company, and Wm. L. Cobb consulting engineer.

Piute, Cal., September 24.

MONO COUNTY.

A prospecting drill is to be placed on the Dondero ranch north of Mono lake and the ground tested for oil.—The Masonic Mining Co. will start work on the recently acquired True Friend claims at Masonic under the management of John Philips.

SHASTA COUNTY.

The 700-ft. raise at the Midas mine, Harrison gulch, has been completed after nearly a year's work. A new hoist will be put in, as this is to be made the main working shaft.

SISKIYOU COUNTY.

Over 300 mining location notices have been filed for record in this county during the last two weeks. Nearly all the no-

tices concern locations of claims on the copper belt along the Klamath river, extending from the mouth of Humbug creek to the State line.

TUOLUMNE COUNTY.

(Special Correspondence).—A boiler and pump have been purchased for the Louisiana mine, one mile north of Tuolumne. When installed the work of unwatering the mine will be begun again. After having lowered the water to the 300-ft. level the work was abandoned several months ago, owing to lack of machinery. — Unwatering the shaft of the Crystalline mine was begun three weeks ago and is now half done. It is the intention of C. W. Ayers, the superintendent, to drift south on the vein from the bottom of the shaft. — J. Ross Clark, J. S. Davies, and R. A. McWilliams have assigned their interests in the Patterson mine to the Pyrenees Gold Mining Co. in consideration of 600,000 shares of the capital stock of the latter concern. The deal is simply the formation of a new corporation to better handle the business of the Patterson mine. Mr. Clark is president of the Pyrenees Gold Mining Co., and Mr. McWilliams, secretary. — Sinking has been resumed at the Longfellow mine at Big Oak Flat. The force has been temporarily reduced. The mill is kept in steady operation. — The Springfield Tunnel & Development Co. has been organized. The principal place of business is Springfield, Tuolumne county, and the directors are W. M. Hall, W. A. Roth, A. G. and A. L. Horner, all of Oakland. — A 25-drill air-compressor has been installed at the App mine. — At the Harvard, on Whisky hill, 60 men are employed, and 30 stamps are dropping. — Operations have ceased at the Black Oak mine, near Soulsbyville. — It is reported that rich ore has been uncovered at the 1,500-ft. level of the Jumper mine. — At the Columbia mine, near Columbia, sinking is in progress. The shaft is over 100 ft. deep, and when it has reached a depth of 200 ft. driving north and south on the vein will be commenced. A cross-cut adit will also be run east to tap the Plummer shoot and another will be driven to cut the west vein. A tramway from the shaft to the mill has recently been completed and the mill was started up a few days ago.

Tuolumne, September 24.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Georgetown Loop Mining Co., owning 25 claims on Republican mountain, has its main adit in 300 ft. A good lode is exposed in the breast; this is believed to be the South America, which produced largely from surface workings many years ago. — B. J. O'Connell, leasing on the Frostberg lode of the Mendota mine, shipped 74 tons of lead-zinc ore to the Independent mill last week for concentration, the result being 20 tons of clean blende concentrate, 25 tons galena and 5 tons pyrite. Mr. O'Connell has also a 65% lead ore, which is shipped direct to the smelter through the Independent Mill Company. — Charles Schragger and Theodore King shipped 700 lb. ore from their Rainbow property near Hale valley which netted them \$1,000. Besides this extraordinary ore they have a 10-in. vein of galena which runs 238 oz. silver per ton and 50% lead. An assay made of some specimens from the property gave 19,604 oz. silver per ton. Buildings are now being erected and everything will be put in shape for continuous winter work. — At the Arapahoe group, covering 11 claims northwest of Argentine pass, owned by Charles Gilleen, Tom Cunningham & Co., although no extensive work has been done, an orebody 35 ft. wide has been exposed in the upper adit, all of which is first-class concentrating material. Near the mouth of this adit there are 12 inches of rich ore. The outcrop of one lode is 30 ft. wide, samples assaying from 50 to 200 oz. silver, $\frac{1}{2}$ to 12 oz. gold per ton and 40% lead. — The Alaska Tunnel & Mining Co., operating on Leavenworth mountain, has been driving on the Germania vein. In the upper adit the Queen lode is 26 ft. wide where cut at 450 ft. from the mouth; it carries many small streaks of mineral in a fine gangue. — A 70-ft. bridge across Clear Creek above Silver Plume to the Josephine mine has been completed, also a boarding house and ore-bins. The adit is in 1,000 ft. and for 100 ft. back from the breast

there is a continuous vein of galena, varying in width from 6 to 18 in., and carrying lead, gold, and silver in paying quantity. — Wm. Jacobs has given a two years' lease and bond on his Star group in Geneva gulch to John O'Day & Co. No work has been done on the property since 1894. The ore is said to assay 480 oz. silver per ton and 25% copper. The lessees have started a new adit which will cut all the four veins of the group in 500 ft. and give a depth of 250 ft. — The Lebanon is another old property which has recently re-commenced shipping. Mr. Maxton, the present lessee, shipped 25 tons of \$40 ore to the Independent mill this week. Shipments will probably be continuous from now on, as the water-power has been put into service to operate the air-compressor, and the workings are in fair shape.

Georgetown, September 21.

MINERAL COUNTY.

(Special Correspondence).—While there is no boom in this district, yet the mining industry is as prosperous as it has been for many years. The output from this point is close to 6,000 tons per month. A large percentage of this is concentrate. — The East Willow Mining Co., Charles Loughridge, general manager, is installing a 20 by 24-inch Norwalk compressor, which was furnished by the Hendrie & Bolthoff Co., of Denver. Mr. Loughridge is making preparations to do a large amount of work as soon as the machinery is in position. — Dewey & Co., of Denver, has a lease on the Mexico. This mine has been idle for a number of years. At present considerable zinc ore is being produced from the old workings as well as some lead which is being put through the mill on the property. David D. Dewey has charge of the mine and mill. — The Crude United Mines Co. is handling 125 tons of ore per day. The ore is sorted in the mine before being brought out for treatment through the mill or for shipment to the smelter. — The new Amethyst mill is also handling a large tonnage.

Creede, September 12.

OURAY COUNTY.

(Special Correspondence).—Sometime during last July, Walter H. Bunce, general manager of the Chipeta Tunnel Co., started operations about 175 ft. below the old workings of the O. and N. property; he will drive a 7 by 7 ft. tunnel 2,000 ft. At this point he expects to make an upraise to the American Nettie quartzite, where a search for mineral will begin. Mr. Bunce formerly operated on the O. and N. and American Nettie properties, and is of the opinion that by driving a tunnel this distance and raising he will be able to open up some fine ore similar to what was taken out in former days. These old properties have produced approximately \$2,000,000. Mr. Bunce is installing a plant of machinery consisting of boiler, Ingersoll-Rand compressor, etc. The plant will be placed several thousand feet below the tunnel portal, where it will be convenient to secure fuel from the railroad. Eastern parties with ample means are behind the enterprise. Michael Collins, foreman for Mr. Bunce, will have charge of the active operations. About 40 men will be employed when the machinery is installed.

Ouray, September 20.

SAN JUAN COUNTY.

(Special Correspondence).—Mining conditions are certainly improving in this district. During the past few months a number of mills that were started last year have been completed and are now producing. The Gold Prince mill, at Animas Forks, is now under cover and the machinery is being installed as rapidly as possible. The foundations are of concrete and the building is made of steel. The machinery is being furnished by the Denver Engineering Works Co. When completed, this mill will be one of the finest and most up-to-date in Colorado. — The Sunnyside mill at Eureka is being enlarged and it is expected that the capacity of it will be doubled when the improvements and alterations are completed. — The Consolidated Eureka Co., operating in Niagara gulch, is driving an adit to tap the veins on its property some 1,500 to 2,000 ft. below the surface. The adit is now about 1,000 ft. long and a contract has been let to Samuel Davis to drive another 1,000 ft. As soon as the mine is properly developed, it is the intention of the manager, Nathan Gregg of Denver, to erect a mill suitable for the handling of the ore. It is

estimated that there is sufficient water coming from the adit to supply a good-sized mill. The power necessary to operate could be secured from either the Animas Power Co. or the Telluride Power Co., both of which are doing business in the vicinity.

The Old Hundred Mining Co., of which Howell Hinds, of Cleveland, Ohio, is principal owner, is doing a large amount of development work in the mine and operating the mill, which was erected last season. The aerial tramway which connects the mine and mill, is made in three sections on account of the grade. The first section is 1,700 ft. long and reaches from the lower terminal on the line of the Silverton railroad to No. 1 tunnel with a vertical rise of 829 ft; the second section is a jig back 750 ft. in length on the slope from No. 1 to No. 2, with a rise of 525 ft; and section No. 3 extends from No. 2 to No. 7 tunnel, a distance of 1,700 ft. with a rise of 1,081 ft. This tramway was built in the dead of winter and anyone familiar with the San Juan country at that season of the year can comprehend the difficulties that had to be overcome in the construction of this tram. It was necessary to build a trail from the gulch some miles in length on the side of a precipitous mountain to a point 500 ft. above the upper terminal, where the material was packed on burros and afterward lowered in a chute by ropes to where it was to be used. The tramway passes through the crusher building at the top of the mill, and after the ore is dumped it passes over a grizzly, the fine going over a Robins belt-conveyor to the ore-bins to be distributed by a mechanical distributor to the various bins above the stamps. The coarse ore passes through a No. 5 McCully crusher and thence to the belt-conveyor. The stamps are fed by suspended automatic feeders. The mill contains forty 1,350 lb. Boss stamps of eight batteries, each battery containing five stamps. The ore is crushed to pass through a 20-mesh screen and passes over 12 ft. of plate in front of each battery; after leaving the plates it passes through quicksilver traps and through sizers to a row of eight Card tables. The middling from these tables is carried to the floor below, where it is re-concentrated on eight more Card tables. The concentrate from the tables descends through pipes to dewatering tables in the lower part of the mill, where a large percentage of the water is taken out and the concentrate goes to automatic driers and from the driers to bins below, where they are sacked for shipment. Arrangements are being made to run the slime from the tables to settling-tanks and thence over Sperry slime-tables. The mill is handling 100 to 125 tons per day and making three to five tons of concentrate. Robert W. Davis, Jr., is general manager.

Silverton, Colo., September 17.

SUMMIT COUNTY.

(Special Correspondence).—A combined London and New York syndicate has been making drill-tests at the North American placer on Swan river. The work has been going on for three months with three drilling-machines constantly in operation. Mr. Tuttle is superintending the work. The ground owned by the company is known to contain some rich patches, but affairs have been badly managed for some years. Most of the ground can be dredged to advantage.—The Reliance Dredging Co. is continuing operations in French gulch under the superintendency of M. McDonald. The water supply of French creek is holding out well and operations can be continued for two months longer.—The outlook for the lessees on the Country Boy is improving every day. The big body of high-grade zinc ore is continuing to open out in width, as it is followed in the winze. This is one of the largest bodies of zinc ore in the West.—The Wellington Mines Co. has now agreed upon the purchase of the Oro mine and the title to that old time producer will be transferred to this company about the end of September.—The assays from the new strike in the upper workings of the Wellington on the West lode, reported last week, gave returns of 1 oz. gold, with about 25% lead and 21% zinc per ton. The erection of the new mill will in all probability be started next month.—The Bay State Co.'s property is situated on North Star mountain, near Hoosier pass, and has lately come into prominence owing to the discovery of a vein of rich ore. Arthur C. Howard, the super-

intendent, has lately made some concentration tests on the ore and has produced a concentrate assaying \$1,832 per ton. An adit is being run to cut this vein at a good depth.—Frisco camp, as well as Montezuma, is adding to the general activity of the county.—The Mary Verna and North American Mines companies resumed control of their properties and will in future conduct all operations themselves. Up to the present the large main development adits have been run on contract by the Southwestern Brokerage & Investment Co. which has now ceased this work. The large power plant at Curtin, which runs the air-compressor, drills, and electric light, passes into the hands of the two mining companies.—The cross-cut in the North American ground will cut at least eight known veins* and the Mary Verna adit is headed to intersect four veins.—The Fisherman mine, at Montezuma, is opening up well, supplying ore for the Lenawa mill. It is capable of producing 100 tons per day, and will have no difficulty in keeping the mill fully supplied for some time.—The Clarion mine is being worked by Chas. Campbell and associates, who are taking out a large shipment of high-grade silver-lead ore.—The Orizaba mine is in bonanza, the pay-streak being now 3 to 6 ft. wide, all of shipping grade. The ore is rich in black sulphide of silver and also carries wire silver. Assays have given 100 to 500 oz. silver and \$4 to \$12 gold per ton, in addition to 20 to 60% lead and 10 to 20% zinc. Shipping will be commenced as soon as the ore-bins are completed and the wagon-road made to the mine.

Breckenridge, September 20.

IDAHO.

BLAINE COUNTY.

Fine-grinding mills and more tables are to be added to the new mill of the Dollarhide Co., at Carriatown, near Hailey. There are 6,000 tons of tailing to be treated. C. C. Ruthrauf has charge.

MONTANA.

MISSOULA COUNTY.

The Monitor mine, near Saltese, has this month shipped 100 tons of copper ore to the Tacoma smelter. The ores are said to net \$59.50 per ton and average 20% copper. A shaft being sunk from the 300-ft. level is down 340 ft. All the ore thus far taken out has come from the 200 and 300-ft. levels during the course of development. The company has 15 men at work.

NEVADA.

ESMERALDA COUNTY.

The new town of Blair at the mines of the Pittsburg Silver Peak Gold Mining Co. threatens to eclipse the old mining camp of Silver Peak, as it is the terminus of the railroad being built from the main line of the Tonopah & Goldfield railroad. On June 1, this year, the preliminary surveys for the line were begun and on the first day of October trains are expected to be running over the 17½ miles of line. Grading for the 100-stamp mill has been started, and the mill will be completed within the next six or eight months. An aerial tramway is being constructed so that the ore may be carried direct to the mill with but one handling of the ore. Two 10-drill compressors are being put in at the mine.

W. H. Fenn of the Evans & Fenn lease on the Palmetto and Death Valley Co.'s ground at Palmetto has returned to Goldfield, as the Walters, Franks-Nesbitt, and Evans-Fenn leases have been consolidated and John Franks has been made superintendent. The consolidated firms have begun work on the Franks-Nesbitt lease, where there is a shaft 150 ft. in which there is good ore. The company is to treat its own ore, having secured the old mill for that purpose. As now arranged, with many improvements, the mill will be able to handle the ore.—A new 20-stamp mill at Pigeon Springs is being constructed by the Buster Mining Co. It is understood that the mill will treat custom ore while not at work on the company's products. When it starts and demonstrates that it will save the values, other properties in the vicinity will begin operations and have their ores treated at this mill.

The richest carload of ore in bulk ever sent out of the Goldfield district was settled for on September 17. It was purchased by the Nevada-Goldfield Reduction Works, and

came from the Frances Mohawk lease on the Mohawk. The car weighed 175 lb. more than 36 tons and ran \$22,861. The net return was \$20,943. The average was \$688 per ton. The ore was shipped in bulk to the mill in a coal car to divert suspicion of its richness. Ore on this lease on the Mohawk was opened a month ago, and already the shipments have exceeded \$225,000.

LINCOLN COUNTY.

(Special Correspondence).—Work on the Barnwell & Searchlight railroad is being rapidly pushed to completion. The power house of the Searchlight Light & Power Co. is completed; the town has been strung with wires and the machinery is on the road.—In the Colorado Mining & Milling Co.'s property, a 20-ft. vein has been cut at a depth of 70 ft., which averages \$10 gold per ton. The shaft will be continued as originally planned to 200 ft. A gasoline hoist has replaced the whip.—The Parallel mine which adjoins the Cyrus Noble Extension on the north has ordered a large pump, and a mill will be installed before the first of the year. The Searchlight Mining & Milling Co. is installing a 70-h.p. steam-hoist, using oil as fuel.—William Usrey, Edwin Beal and Charles Elgin Erdonda, of Los Angeles, have been examining the San Pedro group in which they are interested. The shaft is down 32 ft. in good ore. Their intention is to sink another 100 ft.—L. E. Bamberger, of the Bamberger-De Lamar mine, was here last week and secured some property. He will shortly commence active operations.—In the Annette shaft an important change has occurred at a depth of 100 ft. What appears to be a cross-vein has been cut, effecting the general character of the ore.—The main shaft on the Nevada Searchlight is now down 100 ft. It is the intention to sink for an additional level and cross-cut. There are four veins cropping and the work underway is on the most northerly. Where uncovered by the recent rains fine ore is exposed.—The Searchlight Con. Mining & Milling Co. will install a hoist and begin active operations. Ore has been exposed at the 100-ft. level.—The shaft of the Cyrus Noble Extension Co. is down 104 ft., the first 50 ft. having been timbered. A drift has been run from the bottom, 46 ft. north and cross-cut drift southeast for the same distance. A hoist will soon be installed. Ore is similar to that of the Cyrus Noble, the main shaft of which is only a few hundred feet to the south. Searchlight, September 19.

The recent heavy rains which damaged railroads to the extent of several thousand dollars in Searchlight had the effect of exposing numerous croppings whose existence had hitherto not been known. It also stimulated prospecting, and during the past few days many outfits have gone out to find new veins in the clean-washed gulches. Directly in front of the hotel at Searchlight croppings were uncovered in the street which showed a fine body of quartz, heavily copper stained and carrying some galena. Further down the street another cropping was exposed, from which specimens of free gold were taken. Both these discoveries are within the limits of the Original Searchlight townsite.

LYON COUNTY.

B. B. Hennessy and C. J. Durbrow, who have a lease and bond on the Emerson galena property in Red Canyon, 26 miles from Wabuska, have men driving an adit. The ore that has been taken from near the surface carries lead, silver, and gold. As soon as a road can be built to haul the ore to Wabuska, shipping will be started.

NYE COUNTY.

(Special Correspondence).—Johnnie is having a boom. Real estate has shown remarkable activity. The townsite was sold by the Johnnie Con. Gold Mining Co. to some Los Angeles capitalists for \$50,000, and they have since then sold a number of lots at high prices. The mines throughout the district are showing remarkable improvement. Operations have been resumed in the Johnnie Consolidated and men have been at work on the 700-ft. level to cut the vein. The drifts both north and south on both the 500 and 600-ft. levels are in good milling ore, with occasional rich stuff.—The Globe-Johnnie has made a most remarkable showing. In the bonanza shaft a lode was exposed that gave sensational assays and it was the intention of the superintendent to tap this

rich lode by shallow adits. The first of these is now advanced about 18 ft.; ore $3\frac{1}{2}$ ft. wide has been found and samples taken clean across the face in several places assay between \$700 and \$800 per ton. On the Bullfrog-Johnnie a double compartment shaft was started that will be sunk two or three hundred feet on a body of ore that has been proved to be 200 ft. long and from three to five feet wide. One portion of this vein assays \$126 for three feet wide, but assays from the whole body runs between \$30 and \$65. To the south of this orebody is a shaft 50 ft. deep in ore assaying between \$6 and \$12. Besides this there are two 50-ft. shafts connected by a drift 175 ft. long, disclosing an orebody four and a half feet wide assaying between \$8 and \$42. On the Bullfrog there are three parallel veins. Between these three there are a number of small stringers which are rich.—On the Leadville-Johnnie a shaft is being sunk, from which ore is being sacked that is almost solid galena, assaying 70% lead, 20 oz. silver and \$4 in gold.—Work will soon be started on the Pittsburgh-Johnnie, which is surrounded by the Bullfrog, the Globe, and the Johnnie Consolidated.

Tonopah, September 24.

SOUTH DAKOTA.

LAWRENCE COUNTY.

(Special Correspondence).—The Golden West mine, on Castle creek, seven miles southwest of Rochford, is running full force, and it is said by E. J. Kennedy, the manager, who has brought the proposition to its present successful stage, that mining and milling are being accomplished for 50c. per ton. It is thought that the main fissure vein has been discovered. It stands nearly vertical and was found capped by a flat diorite intrusion to the depth of six or eight feet. The large orebody in the open-cut is now exposed 40 ft. wide and no walls in sight. This rather remarkable ore deposit was described and illustrated in the MINING AND SCIENTIFIC PRESS in the early part of October, 1905.—At the Standby, at Rochford, 20 men are employed blocking out ore and preparing for an extended winter campaign. New battery-blocks are being placed under the mortars of the 60-stamp mill. J. B. Baker is superintendent.—At the Montezuma, two miles north of Rochford, a five-stamp sampling mill is running, testing ore from all parts of the mine. There is more activity in mining now about Rochford than in many years past.

Rochford, September 18.

WASHINGTON.

CHELAN COUNTY.

The Chelan Electric Co. has filed a petition asking for the condemnation and the determining of the compensation to be paid for riparian rights on Chelan river and lands which will be overflowed in developing the water power of the Chelan river. Agents of the electric company have been busy for the past two months buying property and were successful in coming to terms with nearly all of the owners. The acquisition of the rights demanded in the present suit would give them all the power in the river, estimated at 120,000 h.p. If this plant should be put in, it will aid mining near Lake Chelan.

BRITISH COLUMBIA.

YUKON TERRITORY.

Word has been received from the Klondike mines railway that the owners in England are to extend the line next season from Sulphur Springs to Granville on lower Dominion creek, and perhaps as far as Flat creek. Surveyors have been instructed to locate a permanent route this fall, so that work of grading can start early next spring. A preliminary route has been selected to Flat creek. The line will be operating to Sulphur Springs, on the highest ridge of the Klondike camp, two weeks hence. The Government is building a system of fine wagon-roads, radiating to Heads, Gold Bottom, Hunker, Quartz and Sulphur creeks. The extension next year will follow down Caribou gulch, thence down Dominion creek to opposite the mouth of Gold Run. It is believed that the English backers contemplate extending this road up the ancient beds of the Stewart and Pelly rivers, across the Rockies to connect with the transcontinental railway from Edmonton to Dawson.

Personal.

W. H. WEED is at Salt Lake City.

H. DEC. RICHARDS is at Los Angeles.

F. LYNWOOD GARRISON is at Denver.

F. L. BOSQUI is at Lead City, South Dakota.

THEO. F. VAN WAGENEN is at Zacatecas, Mexico.

WILLIAM DEL. BENEDICT has returned to New York.

W. L. HARDY, of Inde, in Chihuahua, is visiting El Paso.

C. A. MOLSON is at Ogilby, San Diego county, California.

M. A. WOLFF has returned to England from Wei-hai-wei, China.

E. A. H. TAYS is examining mines in the Nacosari district, Mexico.

HENRY BRATNOBER has returned to San Francisco from Nome, Alaska.

CHARLES E. BUNKER is visiting the City of Mexico on mining business.

J. W. PALMER, president of the Shannon Copper Co., is at Clifton, Arizona.

F. C. BOWMAN is engaged as constructing engineer at Telluride, Colorado.

KARL EILERS will make New York his headquarters instead of Salt Lake.

FREDERICK BURBIDGE is general manager for the Frisco Mining Co., at Gem, Idaho.

A. E. MAY is the new manager of the Guadalupe mine, at Inde, in Chihuahua, Mexico.

EDMUND SPARGO has returned to Liverpool from the examination of mines in Norway.

FREDERICK GRUNDY, of Los Angeles, is examining mines in Kern county, California.

H. H. CLAUDET is visiting Denver and Nacozari (Mexico) in the interest of oil concentration.

THOS. H. LEGGETT has returned to London from Siberia. He will visit California in November.

GEORGE WILLIAMS has resigned as superintendent of the smelter of the B. C. Copper Company.

G. W. CAMPION is returning to Western Australia, as mining engineer to the Red Hill mines.

F. WALLACE WHITE has left Cleveland to investigate claims in Searchlight district of Nevada.

C. W. PURINGTON is examining mining property in southeastern Idaho and notheastern Utah.

W. H. STORMS has been appointed superintendent of the Yellow Aster mine, at Randsburg, California.

DAVID H. LAWRRANCE, of Denver, is at Silver City, New Mexico, making some important mine examinations.

R. B. NICKERSON has accepted an appointment as superintendent of the Laurentian mine in Ontario, Canada.

GEORGE H. EVANS is at Mexico City. He will examine several mines in the Republic before returning to San Francisco.

S. F. EMMONS is in the American hospital at Mexico City, having been taken with malaria while attending the International Geological Congress.

AMONG American geologists who attended the International Geological Congress at Mexico were: F. D. Adams, H. F. Bain, F. Basom, G. F. Becker, S. Calvin, H. D. McCaskey, T. C. Chamberlin, H. F. Cleland, A. P. Coleman, H. P. Cushing, N. H. Darton, W. M. Davis, E. T. Dumble, S. F. Emmons, H. L. Fairchild, C. W. Hayes, A. Heilprin, E. O. Hovey, J. F. Kemp, C. R. Keyes, H. B. Kummel, A. C. Lawson, C. K. Leith, W. Lindgren, A. P. Low, Marsden Manson, A. M. Miller, W. G. Miller, F. L. Ransome, H. F. Reid, J. W. Richards, H. Ries, R. Ruedemann, C. H. Schuchert, E. C. Shepard, G. O. Smith, W. H. Weed, Olof Wenstrom, J. E. Wolff, and J. B. Woodward.

Books Received.

SYMMETRICAL MASONRY ARCHES, by Malverd A. Howe. This octavo volume of 170 pages, well illustrated, presents in a simple form the method to be employed in the designing of masonry arches according to the elastic theory. It is published by John Wiley & Sons, New York, and is for sale by the MINING AND SCIENTIFIC PRESS, the price being \$2.50, postpaid.

MINERAL LAND SURVEYING, by James Underhill. A technical treatise on the surveying and patenting of mineral land, designed for the use of deputy mineral surveyors and students of mining engineering. It is a practical handbook prepared by an experienced surveyor well known in Colorado, and ought to prove of great service to those engaged in this branch of engineering. It is published by the *Mining Reporter*, at Denver, and is for sale by the MINING AND SCIENTIFIC PRESS; price \$3, postpaid.

PORTLAND CEMENT is the title of the newest book on this important and increasingly interesting subject. The use of hydraulic cement is increasing largely every year, and any treatise which gives the latest information on the subject is welcome. This book, by Richard K. Meade, is a second edition, which shows clearly that it is a work in demand by practical men. It treats of the raw materials employed in cement making, its manufacture, analysis, tests, and uses. Sent by the MINING AND SCIENTIFIC PRESS upon receipt of price, \$3.50. The Chemical Publishing Co., publishers, Easton, Pennsylvania.

THE CALIFORNIA DEBRIS COMMISSION HAVING RECEIVED applications to mine by hydraulic process from Nelson Contracting Company, in Calaveritas Hill Mine, near Calaveritas, Calaveras County, California, draining into O'Neill's Creek; and from Wm. McGuire, in Camden Mine, near Nevada City, Nevada County, California, draining into Greenhorn Creek, gives notice that a meeting to receive any protests will be held at No. 1733 Pine St., San Francisco, Cal., October 15, 1906, at 1:30 P. M.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

MANY tailing piles would contain less value if the mill practice were carried on with more care.

THIRTY new postoffices have been established in Nevada since the first of the year, all of them in mining camps.

CRUDE petroleum makes a satisfactory rope grease for either standing or running ropes on the surface or underground.

IT IS SAID oil-burning locomotives on the Southern Pacific railroad consume three barrels of oil to accomplish what they did formerly with one ton of coal.

LARGE quantities of ore are stored at the various working mines at Cobalt, Ontario, awaiting the time when the Canadian smelters are ready to receive it.

LIMESTONE screenings are superior to sand as a concrete aggregate. Screenings that will pass a 4-mesh sieve, but not finer than an 8-mesh, are the most valuable for the purpose.

THE starting rheostat is placed in series with line and field, and it is immaterial whether it is in the positive or negative lead. Necessarily, the point of satisfactory commutation depends upon the load.

A SERVICEABLE and inexpensive flexible shaft for use in connection with electric motors and similar devices, may be made from what is known as 'tiller rope', a special make of steel wire-rope.

DOLOMITIC LIMESTONE is preferable to plain calcium carbonate as a flux, as it increases the fluidity and fusibility of the slag, while at the same time removing the sulphur as fully and efficaciously as limestone.

PORTLAND CEMENT concrete suffers no harm by freezing after the mass has fully set; its hardening is interrupted, but proceeds again without hindrance after thawing. Damage is to be feared from frost before setting, especially if an excess of water be used.

THE intrusion of dikes does not always result in pronounced metamorphism. Much depends on the character of the rock intruded by the dike. Quartzite is often little effected, while limestone is often completely changed to garnet, chert, or other minerals wholly unlike the original.

IN the operation of mines the mining engineer must learn to discriminate between veins formed by the infiltration of minerals and those which are merely the results of mechanical movement of the rocks—'crossheads.' The difference between these is not always apparent on casual inspection.

ALL students of ore deposition agree that many ore deposits derive their metalliferous content, in part, from igneous rocks and in part from sedimentary rocks, but to give any estimate of the relative amounts of metalliferous materials derived from the original igneous rocks and from the secondary rocks is impossible.

HOW MANY MINERALS may be added to steel to its advantage is not known, but among those most commonly employed are manganese, chromium, carbon,

aluminum, molybdenum, tungsten, vanadium, and nickel. The effect of these several minerals is to harden and toughen steel. They also have a beneficial effect upon cast iron, but in a less degree than upon steel.

For years European specialists, notably Germans, gave much attention to concentration of ores, and although they accomplished wonderful results, as compared with the then rough-and-ready practices of Western America, the time has now come when the best American practice is superior to that of any part of Europe, for now classification, sizing, and concentration are carried to an extreme of refinement not hitherto attempted, or at least successfully accomplished elsewhere. The processes are automatic, mechanically successful, and profitable.

No mineral is more frequently mistaken for valuable ore than garnet. Its comparatively low specific gravity, 3.15 to 4.3, should serve to distinguish it from the mineral for which it is most frequently mistaken—cassiterite, specific gravity 6.8 to 7.1, nearly twice as heavy as garnet. It is also often mistaken for zinc-blende, which some of the brown varieties resemble. The specific gravity of garnet and zinc-blende is nearly the same, that of blende being 3.9 to 4.1. A drop of hydrochloric acid on blende immediately evolves sulphuretted hydrogen, whereas it has no effect on garnet. The mineral occurs in many colors and shades including colorless to white, pale pea-green, amber-colored and honey-yellow, wine-yellow, brownish-yellow, cinnamon brown, rose, red, violet, emerald-green and black.

At Wolfram camp, Queensland, Australia, the wolfram-bearing quartz lodes traverse granite rocks, and carry quantities of molybdenite and bismuth. There most of the mines have, since they were first opened, been held by working miners whose sole object seems to have been to pick out wolfram wherever visible, but the awkwardness of this system of mining is felt as depth increases, and a diminution in the yield becomes apparent. Late advices give the price of ore containing 70% tungstic acid as £84, and the advance has proved an incentive to the miner, but it is probable that the mines at Wolfram camp will ultimately be merged in one or two combinations, with capital sufficient to work them in a systematic and economical manner. Tons of fine molybdenite await a simple and payable process of separation from the broken quartz with which the mineral is mixed.

SHOOTING STARS are distributed through space uniformly as to number and direction of motion. If the earth were at rest they would be observed uniformly as to number and direction of motion from every point of the globe. Owing to the annual motion of the earth around the sun, the greatest number of shooting stars are encountered by observers on the hemisphere directed to the point in the sky toward which the earth is traveling at the instant. The point is called the apex of the earth's motion and is always on the ecliptic about 90° west of the sun. Consequently throughout the year the apex is on the meridian at about 6 a. m. (upper culmination), and at about 6 p. m. (lower culmination). Therefore the greatest number of meteors should be seen to fall in the early morning before daylight, the least number in the evening after sunset. These conclusions are in strict accordance with observation. During its apparent motion from lower to upper culmination from 6 p. m. to 6 a. m., the apex is in the eastern hemisphere and on that account an observer will note the greatest number of shooting stars as coming from the east and neighboring parts of the sky, and the least number are coming from the west.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Unrest in Mexico.

The Editor:

Sir—Under the above caption, 'A Gringo' discusses the wild rumors of war, revolution, and general annihilation of all Americans in Mexico, in the issue of the MINING AND SCIENTIFIC PRESS for August 11; and the Editor further discusses it, in a very sane and common-sense manner in the issue for August 18. As there is more or less error in both, and as the daily press on the United States side of the Border has let its imagination run wild, and as the ides of September has passed and Mexico has not annexed the United States, I beg permission to say a few words, based on 20 years' residence in Mexico, and an intimate association with its people.

Did the troubles in Colorado a year or two ago lead anyone to believe that a revolution was threatening in the United States? When mobs murdered Italians in New Orleans several years ago, did anyone fear that all Italians were to be murdered in the United States? Someone will speak up and say that those outbreaks happened in the United States, an enlightened country. True; nevertheless hardly a month passes that the papers do not chronicle a lynching or a burning of someone by a mob in that same enlightened country, in defiance of all law, the authorities, and humanity. Let me say right here: Such a thing could not happen in *uncivilized* Mexico, without the perpetrators feeling the heavy hand of the law. Before I can be misunderstood, let me say, I am an American to the marrow; but years spent in other countries have broadened my view, I hope, though making me more an American.

The troubles at Cananea were only local, and though bad, cannot be compared with many riots that could be named, that have happened in the United States during the last ten years. That it led to bloodshed was the fault of the Americans themselves. A little tact, a little patience, with a kind firmness, would have prevented it; and the wonder is that under the circumstances and provocation it was not worse.

The papers in the United States, especially along the Border, have been harping on the uprising in Mexico for the past three months, setting the date for September 16. And, on the American side, the comment has been continuous and wilder every day. How is it on the Mexican side? Except among the Americans, one rarely hears the subject mentioned; and when the natives take it up, it is with surprise and in a spirit of ridicule. Among the masses, 200 miles south of the Border, the subject is almost unknown. The American press has harped and speculated on the subject so much that once in a while one sees an article in some of the second-rate Mexican papers discussing the matter, and the whole animus seems to be the fear that Americans are trying to start trouble that will lead to the absorption of their country by force. This is the feeling among the middle class. The educated class looks on the matter as a joke, and if there is an inner opinion, it is one of contempt; for the tone of many of the American comments would lead them to believe that the American people really feared Mexico.

'A Gringo' says, the press reports have been strangely accurate. I should say, the contrary had been the case. We must remember that Mexico, under General Diaz, has been *forced* to enjoy peace for 30 years now, and it would be almost impossible for any revolutionist to get a following. The business man is against it, because it jeopardizes his interests. The *peon* is against it, because

he is the man behind the gun, and would be forced to fall in behind either revolutionist or Government, whichever he had the ill luck to encounter. There is, at present, no known leader who would care to undertake the job, and the *people* are satisfied to let well enough alone. The *peon* is unorganized, by reason of his manner of living, and could not sustain a three days' strike. Where ill paid, he has no surplus; and where well paid he has less (to use a bull). Where well paid, the *peon*, instead of bettering his condition and spending the extra on his family (as saving is beyond his comprehension, he firmly believing it would be doubting Providence to look out for tomorrow), spends it viciously; and, besides spending his earnings, he plays his credit to the limit; hence, he is always in debt. He strikes, and where is he? He must eat, but, being out of employment, he has no salary and his credit stops. He must eat, so the second or third day sees him back at work, whether his grievance has been settled satisfactorily or not.

The educated class is becoming the governing class; the middle class is, as a rule, fairly well-to-do and contented; the *peon*, because of his general irresponsibility, is obliged to work, which keeps him out of mischief. Here you have the actual conditions. Where can you locate the revolutionary element?

Now, as to anti-foreign feeling: There is some jealousy, it is true; that is only natural; but it is not serious. Jealousy is a common human affliction. That there is any serious feeling against Americans, I doubt. The educated classes are intelligent enough to recognize the fact that their country can never be developed without foreign capital, and they, as a rule, welcome it. The middle classes are, by nature, open-hearted, hospitable, and charitable, in all its senses, and are glad to see respectable Americans come into their country. The *peon*, as a class, is the truest friend the foreigner has, and he recognizes the great advantage the coming of the American is to him; although at times he may not show due appreciation, nevertheless he is glad to have the American come; and, where treated kindly and firmly, he makes a good and loyal workman. The *peon* is simple and childlike, and is easily led, be it for good or bad, and the wise man will take advantage of this fact.

Two hundred miles south of the Border, and then only in the State of Sonora, the anti-foreign feeling is unknown, in a collective sense. Along the Border, where the common American (and as a rule he is very common) has mixed with the *peon* class of Mexican, the *peon* has a contempt for the *gringo*, and usually with good cause, and there is more or less animosity. Here, also, you have a worthless, familiar workman who sizes up all Americans as alike, and to be 'done up.' But for this condition, the American alone is responsible. Although there may be local animosities brought about by unwise management, or the over-bearing manner of a few American workmen in Mexico—and often by such bearing from men from whom you would expect better—it can be said confidently that there is no general ill-feeling against Americans in Mexico; and where the American is a gentleman and does not leave his common decency behind him when he crosses the Border, he and his family will be as safe in any out-of-the-way camp in Mexico as they would be in any camp in the United States. There may be some isolated and individual dissatisfaction in Mexico, but that celebrated uprising is a myth, concocted by the American press, and has no real foundation. The courteous, honest, decent, and judicious American is welcome in Mexico, and is as safe as at home; and I speak from a personal, social, and business experience of over twenty years.

E. A. H. TAYS.

Fuerte, Sinaloa, September 16.

Contraction of Furnaces.

The Editor:

Sir—I note in your issue of August 11 a short item as to causes of cracks in reverberatory furnaces. A few years ago when the use of the open hearth, or Siemens regenerative, furnace was not in such general use in steel mills as it is now, much trouble was experienced from the roof falling after a comparatively few heats. This was no doubt caused in many cases by faulty design or materials not the best for the purpose, but one steel-works manager of my acquaintance thought he saw another factor in the trouble.

These furnaces were operated on producer gas, and the flow of this gas was supposed to be reversed in direction through the furnace at certain intervals in the regular process of working. During the working days of the week this would be attended to with regularity, but when the mill was shut down from Saturday night till Monday morning, it was a matter of faith on the part of the superintendent and faithfulness on the part of the furnace tender, which latter seemed sometimes to be found lacking, for it was no uncommon thing on a Monday morning, for the melters to find a cold furnace—that is 'cold' from the melter's standpoint—and the superintendent put a check on this by installing a watchman's time-detector system on the furnaces so that every time the valves were reversed, the time of such reversal was registered in the office.

The result was that 'cold' furnaces soon became unknown in that mill, and whether due to this fact I will not pretend to say, but this mill became famous in open-hearth steel circles for the length of time it was able to run its furnaces without repair of roofs, and the superintendent of the mill was disposed to ascribe much of his success with his furnaces to the fact that he had eliminated from the working conditions the wide range of temperatures the furnaces had before been frequently subject to.

It is hardly likely that this remedy would be practicable on many classes of furnaces, but there is little doubt that many times more attention could be given than is to the matter of keeping furnace brickwork at a fairly constant temperature, once it is heated up, and not let it go to pieces from alternate expansion and contraction, which is one of the most troublesome factors in the wear and tear problem.

Who Is a Mining Engineer?

The Editor:

Sir—The rains are heavy in these Sierra Madres at this season of the year and the mails are frequently delayed in consequence, so your issue of August 4 is only just to hand, with its letter from 'Viator' of London and your resulting editorial, the latter under the caption of 'Who Is a Mining Engineer?' 'Viator's' letter is of interest to all having the welfare of the profession at heart, to me no less than to others, and his point is well taken, but it is the breadth of the spirit shown in your editorial that appeals most to me, who have been through the mill, from mucker at eighteen to superintendent at twenty-eight, and the purpose of this letter is to thank you for it.

While bearing the responsibilities of both married and professional life, I still class myself among those "young fellows of the profession" to whom, in the past and in different surroundings, you have often proffered a word of encouragement. I practice the combination of the mining and engineering professions, granting myself the plain title of 'Engineer,' for want of a better one bestowed on me by a college and because I have been an engineer

in embryo all my life, the attainment of that end having been instilled in my mind by my mother, to whom I owe much of my success, from the time I took my first lessons in walking and talking. I have "had charge of mines, surveyed them, sampled them, and advised clients in the purchase of them," but beyond all that, I have shoved the tram-car underground, have hammered the drill at the face and in the stope, framed the sets for shafts and adits and have had my eyebrows singed by the heat from the assay furnace; further still, I have read and experimented, have been assisted over the hilly places by a partial technical education, obtained at my own expense through force of circumstances, and yet I cannot exhibit a sheepskin bearing my name and a quantity of Latin, all certifying to the fact that I have earned the title of 'Engineer of Mines,' a title granted by the particular technical institution which I had the good fortune to attend for a short time. It has all been an up-hill fight and, now that I am on top, so to speak, it is considerable satisfaction to have you, from whose writings I have learned many a valuable lesson, confirm my personal belief to the effect that I am entitled to subscribe myself an engineer.

I have in my library a book entitled 'The Sampling and Estimation of Ore in a Mine,' the preface of which ends with the expressed opinion of the author that "there is no improvidence so pitiful as the waste of experience." I have made of those words a maxim and embellished them on my wall.

The Position of Amalgamating Plates in the Stamp-Mill.

The Editor:

Sir—The ordinary position of the amalgamated copper plates in a stamp-mill directly in front of the stamps is one which seems natural enough, but it is accompanied by a number of disadvantages.

The object of this letter is to draw attention to the advisability, in nearly all cases, of placing the plates in a room or building quite separated from that containing the stamps or other crushing machinery. Among the advantages connected with this procedure are the following:

1. The absence of noise and vibration caused by the stamps.
2. Much better lighting during daylight hours can be provided.
3. Increased space for working about the stamps, making repairs, etc.
4. Increased space also about the tables, which can be placed as far apart as desired, and built at a convenient height above the floor of the plate room.
5. Better arrangements can be made for altering the grade of the tables, etc.
6. It is easy to arrange a system of pulp distribution, so that the supply of pulp can be shut off any one table, and be distributed equally between the others, or as many of them as may be wished. This obviates the necessity of having to hang up stamps when dressing the plates or collecting amalgam. The ordinary plan of avoiding this by diverting all the pulp on one plate to a single adjoining plate is also obviously bad practice.
7. In consequence, there is no need for the amalgamator to hurry over his work. He can take his time, and do his work thoroughly.
8. By having the doors and windows of the plate room properly secured, casual pilfering by dishonest employees can be prevented, and the risk of robbery by outsiders reduced.
9. It becomes a simple matter to classify the pulp if

desired, before passing it over the plates, and to vary the mode of treatment for each class.

I do not think that there is anything to be said against the separate plate room, except the slight initial cost, the need in some cases of an elevator to give the fall required for the launder conveying the pulp from the stamp shed to the plate room, and the fact that in small mills where only one attendant is employed to look after the stamps and plates, the latter would be less constantly under the eye of the attendant. Even then the advantages in most cases would outweigh the drawbacks.

The benefits to be derived from the separate plate room are such that it should be generally adopted in all new mills. In the majority of mills of old design the change to separate plate room might be advantageously made. I may add that the system here advocated was adopted by the Waihi company some years ago, and, it is almost needless to say, with entire success.

PERCY MORGAN.

Wellington, New Zealand, August 14.

Black Sand.

The Editor:

Sir—In your issue of September 1, I note your remarks on the extravagant expectations created in some minds by reports on the investigations made by Dr. David T. Day into the values of the black sand, generally present in all gold-bearing gravels.

Dr. Day took up the same subject on behalf of the United States Geological Survey about nine years ago, and a partial summary of his report thereon appeared later in Professor Kemp's valuable monograph on the platinum metals. I do not know of any full report on the work in the same line done by Dr. Day at the late Portland Exposition, but as far as known, great results have been promised the mining industry from the laboratory work then performed for the Geological Survey.

So far nearly all the work done under Dr. Day's supervision in relation to the black sand was anticipated many years ago by the writer, being given to the public through the pages of the MINING AND SCIENTIFIC PRESS during October and November, 1894. In those articles the occurrence, distribution, composition, and relative values of the gold-bearing black sand of California were fully discussed, and some practical hints given for their economic working and the extraction of their—often high—gold values.

The impracticability of devising an economically successful use of the iron minerals of these sands had long before that time been demonstrated, and in view of later developments in the iron industry of the United States, any promise of profitable use of these sands, for the production of iron or steel, may be said to be utterly chimerical.

J. A. EDMAN.

Berkeley, Cal., September 9.

The valuable articles mentioned in the above communication did indeed treat the subject in an excellent way. We believe the matter has been overdone—like titaniferous iron ore and gold in sea-water. In regard to our criticism of the exaggerated writing resulting from Dr. Day's well-meant efforts, we quote the following:

"There may be a rich gold mine in your back yard, if you happen to be living on the site of an ancient lake. In scores of places, scattered all over the country, there are pits and mounds of black sand, out of which gold, platinum, and other precious minerals may be extracted. The National Government, itself, is the promoter of this latest mining sensation, which promises to make as many over-night gold-kings as the discovery of Alaska itself."

While the writer responsible for this stuff is prone to

yellow journalism, *The Technical World Magazine*, in which it appears, is a responsible periodical and a widely read publication. Black sand has become—to technical men, at least—an absurdity.—Editor.

Secondary Enrichment.

The Editor:

Sir—The article in your issue of August 11 by Mr. Courtenay De Kalb on 'Secondary Enrichment Upward' describes a very interesting occurrence and I have read it with much interest. While I have no better explanation to offer for the phenomenon described, I would like to ask for further light on some points which are not clear to me.

I do not quite understand how the reactions necessary to form the resulting minerals are to take place at such proximity to the surface and its superabundant oxygen; I have never come across such an enrichment as Mr. De Kalb describes, but it is commonly known that in sulphide copper mines any drift or other opening left standing for a time, without active flow of water, will be covered with crystal of the sulphates of iron, copper, and, if it is present, zinc. This constitutes also a secondary enrichment *outward*, for in my experience at Bingham, in Utah, this action is shown not to be confined to the actual surface, but to affect the ore or walls of the opening for a depth of many inches, even though there are no sulphates visible. Mr. De Kalb describes his surface rocks as being so hard as to resist the absorption of water from the surface, and this would seem to me to indicate that this material would afford little room in its pores for the reactions necessary to be carried out, and little chance for the escape of the waste products after the reaction had been completed. Under the conditions described one would naturally look for the re-concentration of the copper in the cleavage of the rocks, or (as is often the case in Butte) as a complete substitution of some one of the original rock-forming minerals, usually the mica.

Where such reactions as the article describes have taken place in the pores of an eruptive rock, it is unusual to find this rock unaffected by the solutions; some of its original constituents are usually affected, as above stated, thus making room for the re-deposition of the minerals. The finding of voids in the quartz and in the diorite at greater depth is proof of this same action going on, and it suggests to me that possibly the slower action of the solutions at or near the present surface has tended to make a replacement and enrichment *downward*, gradually re-filling these voids, while the rocks, disintegrated by the chemical activity, have yielded to the weather or ice, till the same was removed; then in late geological time, that is, since the Glacial period, the reaction has ceased and the hardening of the surface has taken place by weathering or oxidation of the iron of the mineral.

I do not think that the depth of the development on the Grattan lode was such as actually to establish its permanent poverty; the appearance of pyrite ten feet above the bottom of the shaft, even if this mineral were totally barren, seems to me to give sufficient promise of re-appearance of copper with greater depth, and the mention of the permanent values in a neighboring mine seems to bear out this presumption.

The finding of the barren zone, with voids in place of pyrite, and then pyrite again, might indicate a previous fluctuating water-level and the chance of re-deposition at some depth below.

JAS. W. NEILL.

Pasadena, August 21.

MINERS not infrequently fail to recognize a valuable ore owing to unfamiliarity with other than common minerals.

Three Weeks in Mexico---V.

Cyanide Practice at El Oro.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

The development of the milling practice at El Oro is full of interest. In 1873 a *hacienda de beneficio*, or reduction plant, was erected to crush ore and treat the accumulated tailing from a still older *arrastre*, and to this plant further addition was made in 1885. The mill then included 25 stamps with amalgamating tables. In 1890 the accumulation of tailing made by the stamps was sold to a man from Butte, named Albertson. The tailing he handled was richer than the ore being mined today. Nevertheless, the contract for the treatment of it was cancelled after the purchaser had installed four amalgamating pans with settlers and had started to ship bullion. This was under the regime of General Frisbie. In 1894 a Chilean mill was brought from Chicago, to grind the

part of the 100-stamp mill taken over by the English company, which now controls the property.

The first 100-stamp mill was designed under the Haggin-Frisbie regime and was only expected to crush 4,500 tons per month through a 60-mesh screen. When the property was purchased by the Exploration Co. in 1898, this mill was too near completion to be altered. The slime-plant was added in 1900, after the present company had been formed. W. K. Betty had conducted a series of experiments for the new owners and double treatment was then adopted for the slime-plant; it was only making the best of conditions as they were found; hence the pile of stored tailing now about to be re-treated.

The general plan of treatment was as follows: From the stamp-battery the pulp passed over copper plates and was then divided, by spitzkasten, into 'coarse sand,' 'fine sand' and 'slime,' each product receiving individual treatment. The sand underwent double treatment, in South African style; it was first cyanided in collecting

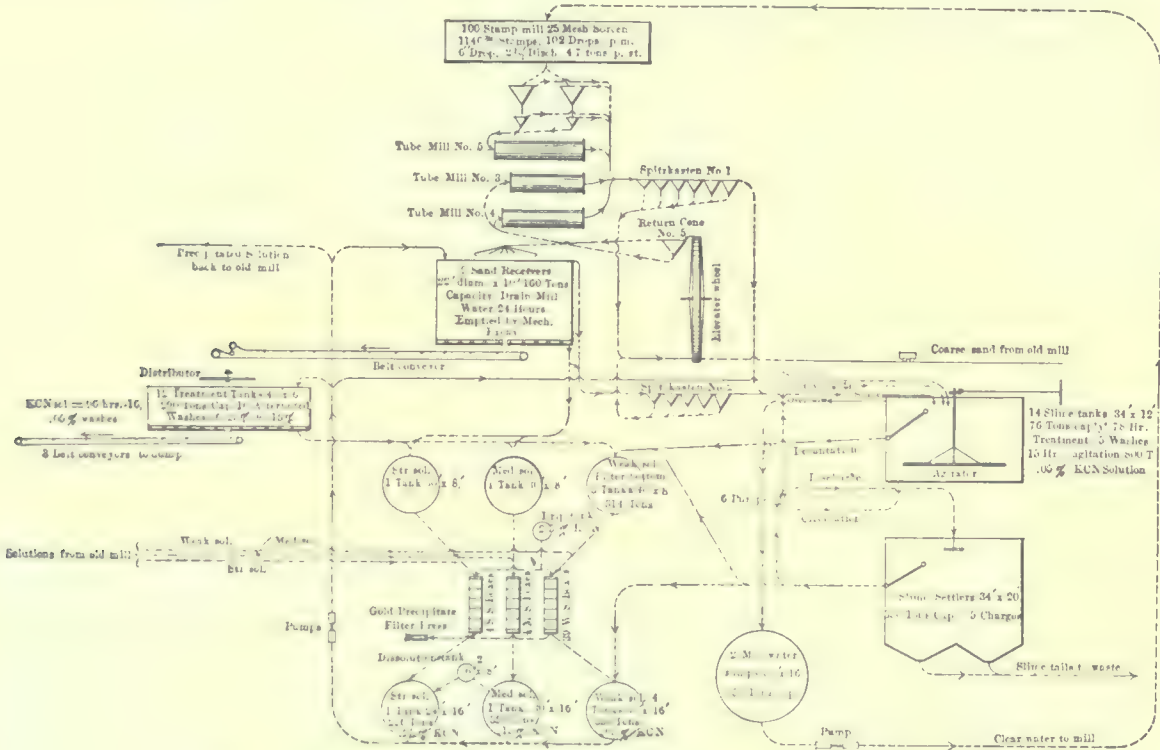

Fig. 1.—Diagram of Cyanide Treatment at Plant No. 2. (September, 1905.)

ore after it had passed through a Comet crusher. The Chilean mill did finer grinding than the stamps, which at that time were also preceded by crushers, of the Blake type. The mill in turn left a dump which, eventually, as methods improved, it became profitable to re-treat. Late in 1894, James B. Haggin bought control. In the following year the old mule-stable was converted into a cyanide annex. Redwood tanks with 4½-ft. staves and 24-ft. diameter were erected; the sump-tanks were larger, with 6-ft. staves. The tailing was carried, in boxes on the backs of *peones* and in hand-barrows, to the vats. Cyanide solution was first introduced by upward percolation through a false bottom, the succeeding water-washes being applied from above. This was followed by precipitation on zinc shaving, with acid treatment for the zinc 'shorts,' the bulk of the precipitate being carefully washed and melted forthwith. The bullion thus obtained was of extraordinary fineness—960 to 980—without the use of any nitre in the melting. This was one of the first successful cyanide plants in Mexico. With only the addition of the small cyanide plant just described, the mine paid \$1,000,000 in dividends up to May, 1898, besides meeting the cost of various installations, including

vats and then dropped into cars which removed it to the treatment vats. The slime was caught in a settling vat and thence went to the treatment house, where it was agitated by jets of compressed air. After treatment, the sand was dropped into cars underneath the vat, while the slime was flushed out with water in the ordinary manner.

In the meanwhile the capacity of the mine grew, not only by reason of the discovery of new orebodies, but indirectly through the cheapening of operations, so that further enlargement of the mill became prudent. In 1905 another, and the last, addition to the reduction plant was made. The new mill of 100 stamps, with its up-to-date cyanide equipment, differs from the old one in five respects:

1. Mechanical handling of the ore.
2. Heavier stamps.
3. Re-grinding in tube-mills.
4. Mechanical handling of sand by distributors, excavators, and belts.
5. Mechanical agitation of slime by stirrers and centrifugal pumps.

The new mill contains 100 stamps, each weighing 1,180 lb., falling 102 times per minute, with a 6-in. drop. The

depth of discharge is $2\frac{1}{2}$ to 3 in. with a new die, and $3\frac{1}{2}$ in. when the die is worn out. Woven brass wire-screens of 35 mesh are used.

The accompanying diagram* (Fig. 1) illustrates the pro-

cess. chemical treatment in the sand-receiver, the idea being to keep the mill-water free from cyanide while effecting a final separation of slime, so as to get a clean product.

The water and slime are drawn off through gates or slots on the side of the vats; these gates are closed by a roll of canvas as the vats fill. The sand, when thus finally freed from the last trace of slime, is removed by a Blaisdell excavator which drops it through a central opening onto a Robins belt-conveyor. This Blaisdell excavator is like a revolving disc-harrow and it has proved a most efficient

Blaisdell Excavator in El Oro Cyanide Annex.

Between the vats there is a belt which conveys to the Blaisdell distributor, working on the same track as the excavator.

cess. From the stamps the crushed ore goes to a system of cone-classifiers and spitzkasten which separate the coarsest sand and send it to the tube-mills for re-grinding. The fine sand from the stamps combines with the similar product from the tube-mills and is elevated by the raff-wheel to the sand-collecting vats. Any slime which may have escaped complete separation and accompanies the sand, overflows from these vats and passes to the slime-plant, joining with the rest of this product that has been eliminated from the sand by the classifiers. The sand is distributed by a revolving mechanism of the Butters & Mein type. There is no

machine. It uses comparatively little power and works smoothly. The belt-conveyor takes the sand (containing now only from 10 to 11% moisture) to the treatment vat, which is fed by a revolving distributor operated by a vari-

Interior of No. 2 Stamp-mill. El Oro.

*Borrowed by permission from 'The Grinding of Ore by Tube-Mills, and Cyaniding at El Oro, Mexico,' by G. Caetani and E. Burt. Trans. A. I. M. E., February, 1906. This is a conscientious and most valuable paper, giving a detailed account of the cyanide practice at El Oro.

able-speed motor, the centrifugal force being so regulated as to throw the sand to the sides or centre of the vat, as required. The charge is 265 tons, dry weight. Ten washes of alternately medium (0.1%) and strong (0.2%)

solution are introduced, six hours apart. This treatment is followed by no less than thirty 'weak' washes, such a lengthy operation being specially designed to extract silver. These 'weak' washes are four to six hours apart and contain 0.03% KCy. Each wash is equal to 13 tons of solution. After treatment, the residue, again using the Blaisdell machine, which moves on rails, is discharged onto a conveyor that takes it to the dump. Here the distribution of tailing is regulated, as the accumulation grows, by a hinged belt-conveyor in two lengths, the last one being swung round according to the contour of the ground.

The slime goes to a collecting vat, from which the thick mud is drawn off at the bottom and thrown into one of the treatment vats. There are twelve of these, each 34 ft. diam. and 12 feet deep. Here it is agitated with a proper proportion of cyanide solution, which is introduced simultaneously. The apparatus for stirring consists of two long and two short arms made of oak bolted to a steel star. The oak arms are solid; they taper outward from a cross-section of 4 by 6 in. to 4 by 4 in. The thick end is bolted to the steel star, which is set on a vertical shaft. When the vat is charged, lead acetate is added immediately. Tests have shown that a beneficial result ensues forthwith, particularly as regards the dissolution of the silver.

Lead salts when added in excess to the cyanide solution, give a precipitate of basic lead cyanide, but when present in small proportion the lead remains in solution, presumably owing to the formation of an alkaline plumbite (K_2PbO_2) by reaction with the caustic alkali, thus:

Mercuric chloride is sometimes employed for the same purpose, producing a reaction with the KCy so as to form a soluble double cyanide, thus:

The most useful effect of these soluble lead and mercury compounds is the removal in the form of insoluble HgS and PbS , of any soluble sulphides that would otherwise retard the solution of gold and silver, and which may even re-precipitate silver already dissolved:

The double mercuric-potassium cyanide also acts as a solvent, attacking gold more readily than simple KCy; and this action is independent of the presence of oxygen, gold replacing mercury:

Silver is similarly dissolved. These reactions have been amply verified. The action of mercuric-potassium cyanide on gold is the basis of patents secured by Keith and Hood; the latter also claims the use of lead as facilitating the solvent effect of cyanide solutions. De Wilde has a patent involving addition of lead oxide to cyanide solution. These compounds also influence precipitation beneficially if they remain in the solution up to the point of entering the zinc-box, as in that case the lead and mercury are precipitated on the zinc, forming zinc-lead and zinc-mercury couples of high electro-motive force. In this precipitation the zinc simply changes places with the mercury or lead, as is also the case when zinc shaving is dipped in lead-acetate solution.

The charge is 60 tons (dry weight) of slime; this is mixed with a solution in the proportion of $2\frac{1}{2}$ solution to 1 of slime, by weight. The solution contains 0.05% KCy*. Agitation continues for six hours. The vat is then filled until there is $3\frac{1}{2}$ of solution to 1 of slime; this is well stirred and then allowed to settle. Settling and decantation consumes eight hours. This part of the pro-

cess is hastened by the use of lime, which is added to the feed of the tube-mills.

The lime has two functions, one of them chemical, the other physical. By virtue of the first it neutralizes the sulphuric acid and decomposes the ferric sulphate contained in the ore, and due to oxidation. Such oxidation may have occurred in parts of the lode before it was mined, or it may have been developed by subsequent contact with the air in its passage to the mill or during treatment. The lime serves in this way to protect the cyanide of potassium or sodium, as the case may be. In slaking, the calcium oxide (CaO) takes up water to form the hydroxide $-Ca(OH)_2$, which dissolves in water to the extent of one part in 800. Lime is preferable to caustic soda, for this particular purpose, because the calcium carbonate is insoluble in water, while the sulphate is but slightly soluble, so that they do not accumulate in the cyanide solution, as is the case with the corresponding sodium salts where $NaOH$ is used as the neutralizing agent. Soluble carbonates are also precipitated by it, leaving caustic alkali in solution, thus:

By reason of its physical function in the mill, lime coagulates slime, so as to cause settling of the particles. The effect is complex. Much of the material classed as slime is of a colloid nature—indeed slime has been recently labeled a 'colloid hydrate.' Such matter when brought into contact with pure water becomes almost gelatinous, and therefore impervious to solution. There are several substances, notably alum, acids, soap, and lime, which, when added to the turbid water, cause the gelatinous matter to coagulate or flocculate, so as to produce a separation into distinct agglomerations. Further, minute particles of ore, whether slimy or not, if suspended in water and refusing to settle, develop a tendency to subside when lime, alum, and other substances are introduced. Although imperfectly understood, these reactions are used largely both in metallurgy and in agriculture.

The slime settles rapidly; within two minutes there is an inch of clear water. This clear solution is decanted and passes to the filter-vat the bottom of which is provided with two or three feet of sand on the top of burlap. This removes any remaining trace of slime, cleaning the solution so that it is fit to go to the precipitation-house.

Returning to the treatment-vat; the slime remaining after decantation undergoes further agitation. The vat is filled with a 0.03% solution and agitation ensues for $1\frac{1}{2}$ hours. Then follow three more successive washes. The vat is then filled for the fifth time and the mixture is thrown by a centrifugal pump into a deep settling-vat. Five of the treatment charges go to one of these vats, of which there are six, each being 20 ft. deep and 34 ft. diameter, with a capacity of 450 tons. The successive charges from the treatment-vat are fed into one settling-vat until it is full of slime, for as fast as the solution gathers on top it is run off, just sufficient time being given for clarification. This clarified solution is so poor in gold and silver that precipitation is not attempted, the solution being used as the first of the washes in the treatment-vat.

The new mill contains three tube-mills. All of them were made by Krupp, at Essen. The No. 3 mill is 19 ft. 8 in. long with 3 ft. 11 in. diameter; No. 4 is 4 ft. 11 in. diameter, and 23 ft. 9 in. long, while No. 5 is of the same diameter as the last, but 26 ft. 3 in. long. The smallest

*Sodium cyanide is used, but all calculations are made in terms of the equivalent potassium cyanide. 100 lb. $NaCy$ is equal to 128 lb. KCy , therefore in practice eight-tenths of $NaCy$ does the work of one unit of KCy . The chemical action is the same, the lesser freight on the more concentrated form of the cyanide making the sodium preferable to the potassium salt.

of the tubes is found to do most work per horsepower required. In Western Australia the tubes or grit-mills (as they are often called) have been cut down to a length of 13 ft., but the ore at Kalgoorlie is softer, so that grinding is more quickly accomplished than at El Oro. The time required is determined directly by the hardness of

silex, a natural flint with characteristic conchoidal fracture; it is whittled into shape in Germany before shipment, arriving in sections 2½ in. thick, 4 in. wide, and 6 in. long. The pebbles that do the grinding come from the coast of Denmark. They vary in size from that of an egg to that of a fist, the average being about three

inches in diameter. They wear well, 6 lb. of pebble being abraded during the grinding of one ton of sand; the consumption of lining being 1.6 lb. An attempt is being made to select some of the flinty quartz, such as occurs in the low-grade ore of the mine, to serve as grinding material. This seems wise; if the hard portions of the ore can be used to grind the soft, the economy is obvious.

At the time of my visit, No. 3 tube was being driven at the rate of 31 rev. per min., while No. 4 and No. 5 made 29 revolutions. The duty of the individual tube-mills cannot be stated; 172 tons of

the rock, for the ore is fed at the upper end and makes its exit at the lower, through a screen. Of the three types of tube-mills, the Abbé can be filled more than half full; this cannot be done with the Krupp mill because it both fills and discharges at the centre. The Davidsen has central feed but peripheral discharge, while in the Abbé mill this is reversed, the feed being peripheral and the discharge central. The last mentioned is built in sections and the driving is done on tires and by gears which circle the exterior of the shell, like a Bruckner furnace. The Krupp tube is made of wrought-iron sheets, welded; it runs on trunnions placed at one end, so that the shell does not come into play as regards the driving of the machine.

The lining of tube-mills is an important matter. Chilled cast iron, both that imported from Krupp's works and that made by El Oro company itself, has been tried; the latter costing one half the former and giving equal wear weight-for-weight. Krupp's lining is from ¾ to one inch thick, El Oro lining is 1½ in. thick. Nevertheless, it is the intention of the manager* to substitute

the coarsest sand from the new 100-stamp mill is re-ground from 35-mesh to 150-mesh, or finer, by the three tubes. In addition, 85 tons per day of the coarsest of the 40-mesh sand coming from the

Cyanide Vats.

Another View of the Cyanide Vats.

old 100-stamp mill is reduced to the same condition, making the total work of the three tubes 257 tons.

The tube-mills get everything above 150 mesh, as separated by cone classification. The aim is to grind to 150 mesh and this is accomplished as nearly as the capacity of the plant will permit. Any oversize is returned—as already described—for re-grinding. The cyanide treat-

* Robert M. Raymond, to whom I am indebted for much valuable information.

ment is based on making a product of sand as nearly 150 mesh as possible, while the 200 mesh and finer are treated as slime. This tube-mill practice has steadily gained in importance, the tendency being to treat a larger proportion of the product from the stamps and to augment their crushing capacity, while enlarging the cyanide annex. This is a proper way of meeting the necessities of a mine the output of which increases in tonnage as the grade declines.

The Value of Detonating Caps in Blasting.

By ROLAND L. OLIVER.

*Detonators or blasting caps are made in several different grades of strength, because some powders require not only a greater, but a different initial detonation than others to convey their maximum energy through a whole charge, and the detonating qualities of each powder vary

the nature and strength of which is as essential to successful results as is the powder itself.

The susceptibility of powder to detonation depends more upon the nature of its ingredients and on the physical conditions previously mentioned than on the amount of nitro-glycerine or other high explosive which it may contain. For instance, ordinary dynamite with 40% nitro-glycerine is easier to detonate thoroughly than a gelatine dynamite containing even as much as 80% of nitro-glycerine, because in the first the liquid nitro-glycerine is merely absorbed mechanically in a dope, whereas in the latter it is chemically transformed with gun-cotton into a gelatinized mass which is harder to detonate and harder to make transmit its detonation through a whole charge of it than ordinary dynamite; that is, a comparatively weak cap will detonate a longer charge of straight dynamite than of gelatine dynamite, yet gelatine dynamite when detonated with a suitable

Looking Down the Valley From El Oro.

with changes in its physical condition—whether it be warm or cold, rigid, plastic, homogenous or otherwise.

The full significance of 'detonation' as applied to high explosives will become apparent in the course of this paper, but it may be stated briefly that detonation is a very much higher degree of explosion than that produced by fire alone or by a blow. While either of these will explode powder under certain conditions, neither of them will cause it to produce its greatest effect. An explosion is merely the rapid transformation of powder from its solid or liquid state into gases which struggle to occupy a space hundreds of times greater than that occupied by the original substance; but in order that these gases produce their greatest rupturing force on the surrounding material, they, too, must be expanded suddenly to their greatest possible volume. This requires a practically instantaneous decomposition and oxidation at maximum temperature into their simplest elements, the result being the highest degree of explosion, which is called 'detonation' and which can only be produced by a peculiar combination of intense heat and concussion, such as is supplied through the agency of detonators, or blasting caps, as they are commonly called. Hence, a thorough detonation of powder is controlled by the cap,

cap is somewhat stronger than ordinary dynamite containing the same amount of nitro-glycerine and possesses greater shattering effect.

A spark will detonate fulminate of mercury; two grains of fulminate will detonate nitro-glycerine; but it requires at least 10 grains of fulminate to detonate gun-cotton. That there is something more, however, than the actual force and quickness of these 10 grains of fulminate, is shown by the fact that although the mechanical force of nitro-glycerine is more than that of fulminate of mercury, ten times more nitro-glycerine, or 100 grains, will not detonate gun-cotton; it will only scatter it; yet a small quantity of dry gun-cotton, which is slower than nitro-glycerine, will easily detonate nitro-glycerine and even wet gun-cotton, which are the two extremes, nitro-glycerine being one of the most sensitive and wet gun-cotton one of the most inert forms of high explosives. Therefore the equilibrium of the different chemical molecules of these powders is susceptible to explosion not merely by the force of the shock, but by different kinds of impulses or vibrations. Another example of the disruptive effect of a particular wave motion without especial mechanical force is the glass globe frequently exhibited in physical laboratories which withstands a strong blow, but is shattered by the mere vibration of a particular musical note, whereas a note of different tone

* A paper read before the California Miners' Association and published by the California Cap Company.

will not affect it. The different degrees of facility with which some explosives will detonate others, and their susceptibility to one kind of detonation more than to another, must now be apparent. Let us next consider the action of the same explosive under different influences. It appears to many as if when a charge of powder explodes at all, it explodes with maximum force throughout; but such is not the case. For instance, a large number of sticks of powder suspended in the air close enough to explode one another (12 to 36 in. apart, according to the kind of powder and size of cartridges used) will explode down the line for a certain distance if a detonator be used to start the first stick, but a point will be reached where one will not set off the stick next to it, showing that each successive stick of powder has lost some of its detonating force.

That its explosive force also becomes weakened as it proceeds down the line may be illustrated by placing under each stick a thin plate of soft steel over the end of a piece of 4 or 6-in. iron pipe. The force of each explosion striking these plates of steel will cup them into the hollow of the pipe and the size of the cups will diminish as the explosion gets further away from the initial detonation. It has also been demonstrated that when the first stick is fired with a weak cap the sympathetic detonation will not extend far down the line; per contra, a very strong cap or one of some other composition to which the powder is more susceptible will carry said detonation much further.

The effect of merely lighting a piece of unconfined dynamite with a squib or piece of fuse without any cap attached is to burn the dynamite quickly without exploding and make a dense smoke which has a disagreeable smell and produces violent headaches. This is simple combustion. Confine another piece of dynamite, then light in the same way and it will explode, but it will belch forth similar fumes. A weak cap (like the old single-force cap) fired in dynamite, will explode it with considerable energy, but there will still be some of the objectionable smoke. Repeat the experiment with a triple-force cap and the dynamite will be detonated with great violence, even when unconfined, developing great explosive force and very little smoke.

This illustrates the difference between combustion, explosion, and detonation, showing that the same powder may be made to transmit its energy by different means and with different degrees of intensity, from a rapid burning to a violent detonation.

The relative strengths of three well-known explosive compounds have been compared when exploded by fire simply and then by detonation. Considering the explosion from simple inflammation of gun-powder as unity, gun-cotton when exploded simply by fire is three times stronger than gun-powder, and when detonated by a cap it is six and one-half times stronger. Nitro-glycerine is five times stronger than gun-powder when exploded by fire and ten times stronger when detonated. Hence these figures explain the enormous force which is given by detonation as compared with that by simple explosion.

Gelatine powders do not transmit their explosive energy through themselves as readily or as far as regular dynamites, hence they require a stronger detonator, larger cartridges and more confinement to completely detonate a whole charge. A 3x cap gets nearly all the energy out of No. 1 and No. 2 dynamite, but gelatine dynamites, nitro-gelatine and other inert powders require at least a 5x cap to develop their energy, and a 6x or stronger cap will do it still better, especially if the charge be a long one. This relation between the length of charge, the diameter of the stick and the strength of caps is another noteworthy fact, more marked with the inert powders than with

ordinary dynamite. Thin sticks require a stronger cap than sticks of larger diameter, and a long charge, especially of slender sticks, requires a stronger cap to convey sufficient impulse through the whole charge; otherwise all the powder in the hole will not be detonated.

The so-called 'fumeless' powders, meaning that their gases are not visible or noxious, are only fumeless in that sense of the word when well detonated. If the fuse burns them, or the cap is too weak, they, too, make 'stinkers' and produce headaches. A poor detonation of gelatine and other inert powders, which does not go all through the charge, will disintegrate some of the other sticks without exploding them, leaving the hole unbottomed and scattering the unexploded powder about the mine, which is dangerous. This sometimes happens when the cap has been buried under several sticks of powder and there is no tamping on top of the charge.

The matter of tamping high explosives is much debated among miners, many asserting that it is unnecessary. As a matter of fact, tamping is not so essential with high explosives as with black blasting powder, because in the one case the expansion of gases is so sudden that just a small proportion get a chance to escape, while in the case of slower powders the expansion is gradual; but in any explosive the better the confinement of the gases the greater will the effect be. The fact is, however, that most blasters use an excess of powder so as to make doubly sure of breaking the ground, and this excess also makes up for the loss of power by the escape of untamped gases.

Close confinement, by ramming the powder well into a hole so as to fill up any spaces around the charge, is also important, since much of its effectiveness may otherwise be lost. For example, a quarter of an ounce of No. 2 dynamite will throw a ball of certain weight from a mortar 300 ft. Leave half an inch air-space between the ball and the powder, and the same quantity of dynamite will throw the same ball only 210 ft., lessening the distance 90 ft. in 300, which is a loss of 30% in efficiency.

Several years ago a mining superintendent in Arizona noticed irregularities in the progress of different shifts. Some of the miners complained of unbottomed holes and bad air. He was supplying them with 40% gelatine dynamite, $\frac{3}{4}$ -in. sticks and 5x caps, shift and shift alike, but with no more powder than his foreman considered was sufficient to do the work. Upon investigation it was found that one shift always rammed the charges with a wooden bar and put tamping on top, but the other shift was not tamping. All hands have been using tamping ever since, and work has proceeded satisfactorily with the same powder and caps.

Another consideration in handling any powder is the diameter of the sticks used. Seven-eighths inch sticks require more confinement and greater initial impulse than one and one-quarter inch sticks to carry the detonation through the charge, because the more powder there is in the immediate vicinity of the cap, the greater will be the initial explosive energy established, and this is essential with gelatine dynamites and other inert powders.

When powder becomes chilled, it is difficult to properly detonate it with the usual detonator, hence the advisability of using a very strong cap in cold weather. Many of the holes are frequently loaded for some time before firing; and even if the powder is soft and normal while charging, it afterwards becomes somewhat chilled in the cold ground. As said before, a 3x cap, or even a double-force cap, will detonate ordinary dynamite if it be soft and plastic. But on the other hand, if it be hard or if it should present a mottled appearance, even a 5x cap may fail to completely detonate it.

(To be continued.)

Pyrite Smelting Without Coke.--III.

Written for the MINING AND SCIENTIFIC PRESS
By LEWIS T. WRIGHT.

The specific heats of pure substances and their latent heats of fusion have been determined in some cases with extreme accuracy and we use these values in our practice, but in our industrial practice we are not often dealing with pure substances and a small amount of impurity may cause important deviations in their physical properties. It is this application of an accurate physical determination of a highly specialized case to the more or less impure bodies encountered in practice that we call theoretical. What are called 'practical' results have, generally, more interest for practical men than those commonly termed 'theoretical,' though the latter, used in a proper manner, are useful in controlling and guiding our practice; and the technician who studies the Why and the Wherefore of practice gladly avails himself of the illumination and suggestion of the so-called theory. There is no gainsaying practical results. Economically they may be good or bad, but they are something that really happens, and practice will long remain unbending before the most attractive theory. The examination of our practical results by the oblique light of theory often brings details into relief that may escape the sight when viewed in the dim perspective incidental to our daily work. Standards of possible efficiency encourage the inventor to progress, and further, the control of practical results by the accurate data of science often serves to reveal gross errors in our practical determinations and indicates the direction to that highest possible efficiency after which we are striving. No excuse will be required for an attempt to examine the results obtained in practice by the light of science, remembering of course that the physical constants we use are merely the nearest approach reached in each case by experiment, and apply to bodies in a high state of purity.

How far is it possible, for instance, to study the comparative calorific values of coke and of iron sulphides? It should be easy; but it must be remembered that the endowed departments of science have not yet determined for us all the physical constants we need and use, and that we, in the haste of output, cannot determine for ourselves.

There are certain fundamental data—such as the heat of combustion of the iron sulphides, of sulphur, and of carbon—that we can use to explain our practice of smelting, and these are stated in different kinds of calories or in British thermal units (B. T. U.)

The calorie (cal.) is often defined as that quantity of heat that is required to raise one gram of water from 0° to 1° C.; but the thermo-chemical equation contains a universal definition that will be found more useful for our purposes. For example, the equation

states that 12 parts by weight of carbon uniting with 32 parts by weight of oxygen generate a quantity of heat that will raise 96,960 parts by weight of water from 0° to 1° C. These parts can be any weight-unit—tons or grams, pounds or kilograms, ounces or hundredweights—the only condition being that the weight-unit used shall be the same on both sides of the equation.

The big calorie (Cal.) contains 1,000 small calories (cal.).

The above equation is therefore often (in round numbers) written

The big Calorie (Cal.) is the one used in this article because it is much more appropriate for technical purposes than the small one, unless it may be for stating the specific heats of substances when, because of the small quan-

ties of heat involved, the small calorie is less cumbersome.

		Per unit-weight of sulphur.
(1)	Fe + O = 66.4 Cal.	
(2)	FeS = 30 = 113 Cal.	3.55 Cal.
(3)	FeS ₂ = 50 = 237.3 Cal.	3.70 "
(4)	FeS + 3FeO = 85.2 Cal.	2.66 "
(5)	S + O ₂ = 71 Cal.	2.22 "
		Per unit-weight of carbon.
(6)	C + O ₂ = 96.1	8.08 "
(7)	Coke with 83% of carbon	6.71 "

The number above given for FeS₂ is open to some doubt, but it is the best available. By analogy with some other metallic sulphides the heat value of the sulphur of the bisulphide should be less than that of the monosulphide. By comparing the two iron sulphides on the basis of the unit weight of sulphur, we find they do not differ much and no great harm will be done if we adopt the value of 3.55 Cal. for both, for present practical purposes, until the value for FeS₂ has been confirmed; and it is interesting to note that the oxidation of ferrous sulphide by means of the solid oxygen* (as in the time-honored case of the smelting of a mixture of sulphides and roasted sulphides or what is the same thing in this sense, namely, imperfectly roasted sulphide) by equation 4 only gives 2.66 Cal. per unit-weight of sulphur. From equations 2 and 6 we learn that one part of sulphur combined with iron is calorifically equal to 0.44 part of carbon or to 0.53 part of coke containing 83% carbon. How far is this relation approximated in practice?

In smelting mixed charges of pyrite and roasted pyrite with cold blast the coke consumption varies with the same make-up of charge, not because of variations in the composition of the charge, but according to the condition of the furnace. With hot blast the furnaces did not exhibit as much variation in this respect. To make a comparison between coke and sulphur, it is necessary therefore to obtain averages, by combining a large number of monthly furnace-runs, in order to compensate for the variable outside influences which appear to be working in one or other direction. In the following table are given results obtained by averaging several monthly runs in which the sulphur content of the charge was much the same for a set; and I hope that in this manner the fuel relation that exists in practice between the sulphur and the coke may be emphasized. All the sulphur in the unroasted ore is calculated as FeS₂ and all that of the roasted ore, slag, flue-dust, etc., as FeS. The sulphur combined with the copper is considered in the same manner as if combined with iron, and no inconvenience will be found to result from this assumption because we are concerned with that portion of the sulphur of the charge that becomes oxidized in the smelting process and not with the whole amount, and it will be appreciated that this amount consumed cannot be combined with the copper because that portion must be left for the matte. The small amount of zinc sulphide present will also not interfere with this method of examination of the fuel-effect of the combined sulphur of our charge, because its sulphur has the value of 3.57 Cal., which is about the same as that of the sulphur of FeS. In the table the results are calculated to unit-weights of sulphur and coke per 100 unit-weights of the actual average charge. The grade of the matte is also given.

RELATION BETWEEN SULPHUR AND COKE, USING COLD BLAST.

	S in FeS, %	S in FeS ₂ , %	Total Sulphur, %	Coke, %	Cu in Matte, %	Furnace Months.
A	13.5	2.2	15.7	8.92	34.8	4
B	11.7	6.8	18.5	8.55	24.4	6
C	12.8	7.1	19.9	8.43	27.9	4
D	7.5	17.5	25.0	7.88	22.8	4

The replacement of roasted pyrite by the raw pyrite is attended in the above practice by an increase in the total sulphur, a diminution of coke, and a lower grade of matte. Of the total sulphur, 70% was oxidized to SO₂.

*Oxygen chemically combined.

On comparing the extreme members of the table we find that one unit-weight of sulphur oxidized replaced 0.159 part coke. From the heats of combustion, it should have replaced 0.53 part coke containing 83% carbon if oxidized by reaction (2) and 0.4 coke if by reaction (4). Comparing results A and C in the above table, we find that a difference of one unit-weight of sulphur oxidized replaced 0.166 coke instead of 0.53 or 0.4 respectively, as indicated by theory. Comparing A and B, which are rather close together, we find that one unit of sulphur replaced 0.188 part coke. Here are practical results of great uniformity, as such evidence goes, in the fuel relation between the sulphur and coke. It must not be forgotten that the grade of the matte is progressively varying in the above tabulated results, and also that some of the oxidization of the sulphide was taking place by means of the reaction between the ferric oxide of the roasted ore and the sulphide which in equation 4 equals 2.66 Cal. per unit-weight of sulphur or 0.4 coke containing 83% carbon. Of course the unit-weight of sulphur in question was producing heat in the furnace equal to 0.53 or 0.4 coke, according to whether it was oxidized by solid or gaseous oxygen, but it did not replace the amount of carbon it should have done. Only an examination of a thermal balance sheet would reveal why it did not do so, and it may be that by nursing the coke when the increased amounts of pyrite were put on the charge, less coke might have been used, and it may be that other metallurgists using cold blast may find a more favorable practical relation between the sulphur and the coke in the case of mixed charges if their attention is called to the facts above cited.

I will now give a similar fuel comparison between sulphur and coke in the case of warm blast. A recent writer on this subject has suggested that it would be more appropriate to call our heated blast warm rather than hot, and there is the more reason for agreeing with him because it does seem that a moderate heating of the blast serves all that is needed of it and that there is no need to use the high temperature employed in iron smelting and obtained with brick stoves. In the following table are given the results obtained with warm blast with three furnaces similar in design and operation. Each result is the average of six months' work with the same furnace. The three furnaces were working under the same conditions and exhibited much greater regularity in respect to coke consumption day by day than was shown by the same furnaces when previously working under cold blast.

RELATION BETWEEN SULPHUR AND COKE, USING WARM BLAST.							
	Sulphur in FeS.	S in FeS ₂ .	Total Sulphur.	Coke.	Matte % Cu.	Blast oz.	Rate of Smelting: Tons per sq. ft. per 24 hr.
E.	5.51	15.16	20.67	4.0	31.0	28.4	8.58
F.	7.20	12.60	19.80	4.5	31.6	28.6	8.41
G.	7.15	11.30	18.45	4.8	31.4	28.4	8.47

It will be noticed that, as in the case of cold blast, the coke consumption diminishes with addition of sulphur to the charge. Special attention was given to the coke consumption to reduce it to a minimum. The furnaces ran with great regularity and very fast, as will be seen from the average rate of smelting. It is calculated that 71% of the sulphur was oxidized to SO₂. On comparing the extremes, it is found that a difference of one unit-weight of sulphur oxidized is equal to a difference of 0.508 coke. This is certainly a surprising result, in contrast to those obtained with cold blast. These relations, which were not discovered at the time, serve to illustrate the value of warm blast, which, by increasing the temperature in the smelting zone, ensures more active and regular smelting of the charge.

The above results also enable us to calculate the vanishing point of carbonaceous fuel on a pyrite charge. How much additional sulphur should replace the 4% coke used

when 20.67 units of sulphur existed in 100 units of charge and 14.67 units of sulphur were oxidized, or how much sulphur must be oxidized per 100 of charge to enable the coke to be entirely eliminated. From the extremes in the above table, we calculate that an additional 7.87 units of sulphur oxidized would, if the same relation between sulphur and coke continued, be sufficient to replace all the coke. That is, other things being equal, 14.67+7.87 or 22.54 of sulphur oxidized per 100 units of charge should enable the charge to be self-smelting. This is precisely what was later found to be possible, and often the furnaces ran with just that amount of oxidation. It is better, of course, to have more, say 25 units of sulphur per 100 of charge.

In setting forth furnace-results for such a discussion as this, I find it convenient to have the average charge stated and not the official charge, which is varied from time to time; it is also cumbersome for the purpose of calculations and comparisons to have the charge stated, as it often is, in some odd number of pounds as it is given to the weighers, the foreman taking off or adding on a few pounds of the different constituents of the charge from time to time according to the working of the furnace and the class of material used, and the men perhaps using more coke than is accounted for on the charge-sheets,—for is not the coke pile handy?

Having shown the relation between carbon and sulphur as fuels in copper blast-furnace practice, I would like to draw attention to the thermo-chemical aspects of the cases cited, believing that such evidence as exists, even if but approximate in some of its details, will be instructive. Again I must refer to iron smelting in blast-furnaces because it has been extensively studied for many years by highly competent observers and the heat balance-sheets prepared by them may serve as a model for those who desire to emulate an admirable example, but in so doing I want to emphasize the fact that the two operations of iron smelting and pyrite smelting are chemically opposite processes, though similar in their main physical features. The first is a reducing process, the iron oxide being reduced to metal by the agency of carbon monoxide. And the carbon is not merely the only available fuel for the physical effects of melting, etc., but it is necessary for the chemical work of the furnace. In the smelting of pyrite, on the contrary, we require to oxidize and not to reduce, and carbon, however useful it may be in raising temperature, remains counter-active to the chemical requirements of the problem.

For centuries copper metallurgists have been groping with the irrational use of carbon as a fuel, allowing it to impede the work of roasting by its reducing action and counter-active effect on the required oxidation. There is no doubt that by high development of the muffle principle, much of this counter-active effect might have been avoided in the reverberatory work in the old practice of smelting sulphide ores after preliminary oxidation. We have learned that sulphur will replace coke, as imagined and almost demonstrated by Hollway, whose method of first melting the sulphide in a cupola with coke and then converting it in a Bessemer converter is precisely what we now practice with success, with the additional advantage that by promoting the oxidation and performing the first melting without carbonaceous fuel or its minimum, we combine two highly economical pneumatic processes and conduct both by the heat of combustion of the iron sulphides without the counter-active influence of carbon.

It is usual to state iron furnace results per unit-weight of pig iron. For the purpose of illustration, I have taken a case from Mr. Gayley's practice as studied by Prof. Joseph W. Richards (Trans. A. I. M. E., p. 703, July, 1905) and have arranged his figures according to a unit-

weight of charge and not according to the weight of the valuable product produced by the furnace. I also use the big Calorie in preference to the small one.

IRON BLAST-FURNACE PRACTICE, WITH MOIST BLAST.

	* Calories per unit-weight of charge.
Heat distribution.	
Reduction Fe_2O_3	0.738
Reduction SiO_2	0.030
Expulsion of CO_2 from limestone.....	0.081
Decomposition of water in blast.....	0.065
Evaporation of moisture in charge.....	0.051
Heat in pig iron.....	0.112
Heat in slag.....	0.105
Heat in escaping gases.....	0.198
Radiation, etc., and undetermined.....	0.348
Total.....	1.728
HEAT DEVELOPED.	
C to CO.....	0.591
C to CO_2	0.959
Heat in blast.....	0.178
Total.....	1.728

By studying such a table of results we can cultivate our sense of proportion and realize at a glance what particular items cause the largest heat expenditures; we can also learn to distinguish those factors in which improvement is possible from those that are, like the reduction of the ferric oxide, inevitable to the process. We see how much heat is lost in escaping gases and in the molten iron and slag. In order to contrast this practice with pyrite smelting without coke I have prepared the following table in order to show to what extent the two processes resemble or differ from each other.

TABLE A.—PER POUND WEIGHT OF CHARGE.

	Iron blast furnace.	Copper pyrite smelting.
Air used, volume.....	26.4 cu. ft.	33.00 cu. ft.
Air used, weight.....	1.9 lb.	2.43 lb.
Slag produced.....	0.26 "	0.55 "
Pig produced.....	0.45 "	
Matte produced.....		0.23 "
Charge smelted per sq. ft. of hearth-area per min.....	8.7 "	12.5 "
Blast-pressure per sq. in.....	15.0 "	2.0 "
Height of ore-column.....	70.0 ft.	6.0 ft.
Temperature of escaping gases.....	230° C.	800° C.
		(estimated)
Calories per unit-weight of charge developed or expended.....	1.728	1.082
Critical or working temperature.....	1,510° C.	1,250° C.
		(estimated)
Temperature of blast.....	382° C.	222° C.

In contrasting the two processes we notice that the copper furnace takes more air but at a much lower pressure, the last because the height of ore-column is so much less. The slag in pyrite smelting is more than double the other, but the matte is in weight but one half as much as the pig produced by the iron furnace. The copper furnace drives about 50% faster. The temperature of the escaping gases is unfortunately very much higher in the copper furnace because of the low ore-column, the faster driving, and the uncomfortable fractional combustion of the sulphur of the pyrite. The temperature of the escaping slag and metal is higher in the iron furnace because of the high temperature of fusion of cast iron, as compared to that of copper matte. The temperature of the in-going blast is much higher in iron smelting and the total heat required is greater, because of the large amount of endo-thermic chemical work to be performed. The numbers given in Table A will serve for the preparation of a heat balance-sheet for pyrite smelting, per unit-weight of charge. The important items are as follows:

HEAT IN ESCAPING GASES.—The temperature of these was not determined, but estimated, from the color of the heated particles of flue-dust on the top of the furnace, at 800° C. It is an unfortunate feature of pyrite smelting that the furnace-top is so hot, because, as explained in a previous article, the sulphur of the charge burns in

a fractional manner and partly toward the top of the furnace. The temperature of the gases being high enough to agglomerate some of the flue-dust, this, in falling back to the sides of the furnace helps in building the accretions which form the scaffold, the closing up of which eventually causes the shutting down of the furnace. The specific heat of the gases is calculated for a gas of the following composition:

SO_2	0.100
O_2	0.058
N_2	0.842

Total..... 1.000

On an average, it is probable that the percentage of SO_2 in the furnace gases would be less than 10%. Allowance has been made for the generally neglected increase of specific heat at increasing temperatures. The mean specific heat of a gas of the above composition was found to be 0.392 at 800° C. or 0.00049 Cal. per unit-weight of charge per 1° Centigrade.

HEAT IN SLAGS.—This has been calculated for a temperature (estimated) of 1,250° C. The specific heat of the slag was found to be 0.00016 Cal. per 1° C. (between 0° and 100°) The increase in the mean specific heat was assumed to be 0.07% for each degree and the latent heat of fusion given by Voigt for 2 (FeO) SiO_2 , namely, 0.085 Cal., was taken. The total heat in the slag at a temperature of 1,250° C. was thus calculated to be 0.46 Cal. per unit-weight of slag; $0.55 \times 0.46 = 0.253$ Cal.

HEAT IN MATTE.—The specific heat of this between zero and 100° C. was found to be 0.00016 Cal. The mean increase with increased temperature is estimated at 0.000064 per degree. The latent heat of fusion was calculated for a mixture of $\frac{1}{3} \text{Cu}_2\text{S}$ and $\frac{2}{3} \text{FeS}$ by the empirical rule. In that manner the total heat in the matte was calculated to be 0.33 Cal. per unit-weight of matte for the estimated temperature of 1,250° C. or per unit-weight of charge; $0.23 \times 0.33 = 0.076$ Calorie.

HEAT IN COOLING WATER.—This was determined and found to vary between 0.06 to 0.13 Cal. per unit-weight of charge, according to thickness of crust and rate of running of furnace. The mean loss, namely, 0.095 Cal., is taken.

THE HEAT IN THE MOISTURE OF THE CHARGE.—The average moisture was 3.5% and this is consequently 0.035 by 0.6 Cal. or 0.021 Cal. per unit of charge.

The decomposition of the limestone is 0.04×0.451 , or 0.018 Cal. per unit of charge.

The decomposition of water (moisture) in the blast is calculated for ordinary atmospheric conditions.

Some allowance for loss of heat by radiation is necessary.

For the heat developed at the rate of 0.25 unit-weight of sulphur oxidized and adopting the heat of combustion of FeS, namely 3.55 Cal. per unit-weight of sulphur, we have,

$$0.25 \times 3.55 = 0.89 \text{ Cal.}$$

The heat of combination of 2 (FeO) and SiO_2 , I do not know. That of FeO plus SiO_2 as given by Prof. J. W. Richards (Metallurgical Calculations—Electro-Chemical and Metallurgical Industry, March, 1905) is 0.189 Cal. per unit of Fe. For the slag in question, which approximates 2 (FeO) SiO_2 , 60% of the above value has been taken.

$$0.189 \times 0.6 \times 0.22 = 0.025 \text{ Cal.}$$

HEAT IN THE BLAST.—This is $0.303 (222^\circ) + 0.000027 (222^\circ)^2 \times 2.13 \times 1000$, to reduce to big Calories, 0.167 Cal.

The calculations are made, as is usual, from a temperature base-line of 0° C., and I have added the equivalent percentage-weight of coke that would furnish the amounts of heat in question.

A summary of these items gives per unit-weight of charge:

	Calories.	Coke equivalent % Calories×100
Heat expenditure.		6.71
Escaping gases.....	0.392	5.84
Heat in slag.....	0.253	3.77
Heat in matte.....	0.076	1.13
Heat in cooling water.....	0.095	1.40
Evaporation of moisture in the charge.....	0.021	0.31
Decomposition of limestone.....	0.018	0.27
Decomposition of water in blast.....	0.073	1.09
Radiation and difference.....	0.154	2.30
Total.....	1.082	16.11
Heat developed.		
Combustion of sulphides.....	0.890	13.26
Combination of FeO and SiO ₂	0.025	0.37
Heat in blast.....	0.167	2.48
Total.....	1.082	16.11

We see that the heat in the blast is only about 40 % of the heat in the escaping gases. A hot-blast stove heated by these escaping gases should easily furnish the temperature required, but it would have to be so arranged as not to impede the escape of the gases to the stack or interfere with the operation of the furnace. It is obvious that the slag produced rises or falls with the oxidation of the iron sulphide and the effect of changes in these particulars can readily be estimated.

On first investigating the heat expenditure by inferential methods I was inclined to believe that the work of a pyritic furnace could be carried on with less than the above amount of heat. I had not allowed enough for the hot top, so persistent and annoying with all pyrite charges.

To give the values of the segregated items of heat-expenditure a form entirely practical, I have annexed to each the equivalent percentage weight of coke of 83% carbon burned to carbonic acid that would produce the amount of heat in question. This is obtained by dividing the calories per unit-weight of charge by 6.71, which is the calorific value of the coke (see equation 7), and multiplying by 100 to bring the result to a percentage.

The fundamental principles of thermo-chemistry, such as the conservation of matter and energy, are like those of other established sciences, beyond cavil. Certain numerical data, such as the specific heat of a substance, may be open to a little doubt, but this doubt rests generally within small limits that can be neglected in practice.

The heat in the cooling water takes an amount of heat equal to a fuel consumption of about 1.5 % coke. The loss of heat in the escaping gases is serious, but even if it could be reduced one-half by discharging them at a temperature a little above that of the iron blast-furnace with its 70 ft. of ore-column, the loss of heat in that manner would equal about 2 % coke. These heat-losses are inevitable. A furnace making much slag loses proportionately more heat. A study of the heat-losses of a furnace is instructive, since it is possible to calculate fairly closely what they may be for any case. To follow this path of inquiry a little further, we may ask what would be the heat requirement in terms of coke (83 % carbon) for a charge consisting only of slag. This is the simplest case we can imagine. The chemical work is nothing and we have only to do with physical properties.

In the iron furnace the radiation losses are generally included with the 'difference' or 'undetermined.'

The heat in the cooling water may be equal to 2 % coke.

That lost by radiation is perhaps as much. The heat in the escaping gases will hardly be much less than 4 % coke. The simple heat in the melted slag will require about 6 % coke. Thus, in order to melt a neutral substance like dry slag in a water-jacket furnace, an amount of heat will be required in terms of coke percentage, thus:

Heat in slag.....	6.0
Heat in cooling water.....	2.2
Heat radiated.....	1.5
Heat in decomposing water of blast.....	1.0
Heat in escaping gases.....	4.0
Total.....	14.7

According to the accepted heat of combustion of FeS, this amount of heat is equal to the combustion of 27.5 % of the charge as sulphur. (The higher amount of sulphur in this case over that of pyrite is because one unit-weight of slag is produced per unit-weight of charge.)

The metallurgist has to face the facts, and no amount of ingenuity on his part will enable him to produce matter and energy from nothing. There will be a minimum heat-expenditure, below which he will not be able to go in any particular operation. His concern is not to exceed this irreducible minimum.

It has been shown in these articles that the smelting of pyrite has been carried on without coke with warmed blast when the sulphur oxidized equalled from 23 to 25 % by weight of the charge, and also that the heat of combustion of the oxidized sulphur supplemented by a small addition to the temperature of the blast, accounted for the necessary losses of heat from the furnace. It has been further shown that with warmed blast and when the amount of sulphur oxidized was from 13.1 to 14.9 % of the charge and a small percentage of coke was employed, the fuel-relation between sulphur and coke approximated that indicated by theory; and also that the vanishing point of coke on the charge with additional sulphur oxidized, agreed with that calculated from the relation discovered in practice and very closely with that suggested by theory.

Thus, as regards quantity of heat, theoretical considerations confirm and explain the practical results. There still remains another point of view, and that is the *degree of temperature* as apart from quantity of heat. For example, we may have an infinite supply of heat at a temperature one degree lower than that of the point of fusion of copper matte and never be able to melt it. This point of view of temperature suggests two important questions; what is the working temperature of a copper-matting furnace? and what is the temperature of combustion of the iron sulphide?

The working temperature must be higher than that at which the matte and its accompanying slag solidify. The point of fusion of copper matte is about 1,180° C., and that of the accompanying slag 1,100° C. The working temperature must therefore be higher than 1,180° C.; I have judged it to be 1,250° C.

Now we have to determine the temperature of combustion of the iron sulphide. Pyrite does not burn homogeneously, and we are therefore not concerned with its temperature of combustion, but with that of the residual iron sulphide (FeS) left on the heating of the pyrite. (It may be that the iron sulphide in question may be not precisely of the exact formula, FeS, but much more complex, though closely approximating to such formula, that moot point will not affect this technical discussion.)

To calculate the temperature of combustion of FeS burning in air, we must know what excess of air is employed. I have already shown that an excess is required. Analyses of the furnace gases taken from the immediate top of the furnace charge and in such a manner that no air from above the top of the charge could contaminate the samples, gave from 5 to 10 % of SO₂. Calculation shows that FeS burning to FeO and SO₂ in 50 % excess of air would give a gas of the following composition: 9.7 % SO₂, 7.4 % O₂ and 82.9 % N₂. The temperature of such a gas would be raised by the heat of combustion of sulphur (heat equation No. 2) from 0° to 1,319° C. With 100 % excess of air, the gases would consist of: 7.24 % SO₂, 10.7 % O₂ and 82 % N₂, and their temperature would be 1,032° Centigrade.

It will be apparent that with a range of air-excess such as is revealed by the composition of the furnace-gases, the temperature of combustion of the iron mono-

sulphide is likely either to be below the melting point of the copper-matte or dangerously near it, and there need be no surprise if our attempts to smelt pyrite without coke and with cold blast failed. The temperature of combustion of the iron sulphide can easily be supplemented by raising the temperature of the blast or by using some coke; but the latter will have a counter-active effect upon the oxidation of the pyrite and this we desire to avoid.

Thus the use of warm blast is a logical sequence of a theoretical examination of the heat and the other reactions involved; and these in their turn explain our practical experience that, without coke and with cold blast, pyrite is not self-smelting.

Cyanide Poisoning.

*In cases of poisoning, everything depends on prompt action, for the chance of recovery is extremely small after the lapse of a very few minutes if a fatal dose has been taken. One person should be despatched for the nearest medical assistance that is available, but no delay in treatment should be permitted to occur on this account. The first care must be to neutralize the rapid poison by the antidote, and then to empty and wash out the stomach as soon and as completely as possible.

The antidote consists of two solutions sealed up in bottles, and a sealed powder. The two solutions are to be first mixed together in the tin vessel in which they are packed, by breaking off the sealed ends of the bottles. The tube containing the powder is also to be broken and the whole of the powder added to the mixture, and the dose is to be administered as soon as can possibly be done. If the patient is still conscious, he must drink the antidote at once without waiting for the insertion of the stomach tube, but if not conscious, or not responsible, then a small gag must be firmly inserted between his teeth, so as to prevent the stomach tube from being bitten off, and the tube is then to be passed down his throat and into his stomach. The antidote is to be poured down the tube, and is then to be followed by some water.

In any case, either before or after the antidote has been taken, the stomach tube is to be inserted, and about half a pint of water is to be poured down it, the patient being placed in a reclining position, a little raised from the ground. The insertion of the tube may produce vomiting; this, however, is entirely favorable to the course of the treatment. When the last of the water is placed in the funnel, and before it has all descended into the tube, the funnel end of the latter is to be lowered so as to cause the tube to act as a syphon, and the stomach emptied as much as possible of its contents. Fresh water is to be poured down the tube, and the stomach again emptied, and this is to be repeated several times, so as to thoroughly wash out the stomach. When this has been done, the tube can be withdrawn.

If the tube be not at hand, every endeavor must be made to induce vomiting after the administration of the antidote, while an equal endeavor must be made to cause the patient to swallow more of the antidote between the intervals of vomiting, if the administration be not already and completely made.

Vomiting may be induced by an emetic, like mustard, or by tickling the back of the throat with a clean feather, or a piece of clean india rubber tube, or the finger. An ample quantity of warm water should be swallowed and vomited, so as to wash out the stomach as in the previous case. Should warm water not be at hand, cold water may be employed in its place.

As soon as the stomach has been satisfactorily emptied

and washed, and the stomach tube withdrawn, steps should be taken to bring about artificial respiration. Should the patient appear to be in a state of collapse, and his breathing have ceased to be noticeable, the application of smelling salts or of ammonia to his nostrils may itself induce breathing again; but if this be not immediately successful, the patient should be treated as is done in cases of partial drowning or suffocation.

Medical assistance should by this time have arrived; indeed, if the patient be conscious, there is now great hope that the worst effects of the poison will have passed off, particularly if the details of the treatment have been all carried out, for cyanide poisoning is usually fatal within twenty minutes.

The package for treatment should consist of a tin vessel with lid, in which are packed:

- (a) A hermetically sealed bottle, containing $7\frac{1}{2}$ grams of ferrous sulphate dissolved in 30 c. c. water; and
- (b) A hermetically sealed bottle, containing $1\frac{1}{2}$ grams of caustic soda dissolved in 300 c. c. water; and
- (c) A tube containing 2 grams of magnesia.

There should be also a gag for the purpose of opening the clenched mouth of an unconscious person, and a stomach tube, that can be passed through the gag and down into the oesophagus into the patient's stomach. This is very easy to effect, but several persons in charge of the plant should receive instructions from the nearest medical man as to how to insert a stomach tube so that they may know how to use it should occasion at any time arise.

The apparatus* should never be allowed to be removed from its place, but always kept complete and ready for an emergency. It is advisable to keep it in duplicate, in prominently marked positions in the works.

IN NORTHERN RHODESIA, South Africa, Broken Hill is the present railway terminus. The mining field consists of a number of kopjes which are to be quarried for the zinc and lead ore which they contain. Of this ore there is said to be 750,000 tons in sight, going down to the water level at 30 ft. The mines are now being worked, and the first total shipment of zinc ore was sent from Beira to Swansea, Wales, in August. The zinc ore is quarried and calcined on the spot. The ore gives 50 or 60% zinc, and the cost of mining and sending the ore to Wales, including all charges, should be about \$19 per ton. Arrangements are being made for continuous shipments, and it is intended to work the mine up to 500 tons of ore per day. Railway surveys are being made to Bwana M'Kuba, about 100 miles north of Broken Hill. Mines there are rich in copper. The old workings by the natives are 2,500 ft. in length, and 100 ft. deep; they show two veins, one 12 ft. and the other 8 ft. wide, with a space of 30 ft. between them. The two come together and form a body of ore 12 to 15 ft. in thickness. The veins have been proved to a depth of 280 ft., and the copper averages 15%. A feature of the mines is the extraordinary malachite caves, which go down to a depth of 60 ft. at one place in malachite which contains 35% copper.

ALL science starts with hypothesis—in other words, with assumptions that are unproved, while they may be, and often are, erroneous; but which are better than nothing to the seeker after order in the maze of phenomena. And the historical progress of every science depends on the criticism of hypothesis—on the gradual stripping off, that is, of their untrue and superfluous parts—until there remains only that exact verbal expression of as much as we know of the fact, and no more, which constitutes a perfect scientific theory.

*From the *Monthly Journal* of the Chamber of Mines, Western Australia.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

ORE-CONCENTRATOR.—No. 829,443; Walter R. Thurston, Douglas, Arizona.

A concentrator comprising a stationary hopper having discharge-openings, a distributor below the hopper for conducting the material discharged from the hopper, an oscillating disk-shaped or concave pan below the distributor for receiving the material from the distributor at points adjacent to the outer edge of the pan, an overflow-pipe for the waste having an inner sleeve passed centrally through the pan, and adjustable vertically within the pan, a stuffing-box on the pan through which the pipe passes, a central shaft for supporting the pan and overflow-pipe, means for oscillating the pan and overflow-pipe about the axis of the shaft, a spout leading from the overflow-pipe, and a valve-controlled discharge-spout leading from the pan at a point exterior, but contiguous to, the overflow-pipe, for the discharge of the concentrate.

ROASTING AND VOLATILIZING FURNACE.—No. 829,843; Selden I. Clawson, Salt Lake City, Utah.

In an ore-roasting furnace, the combination, with a revolvable cylinder, having a fire-box, a central muffle extending through the cylinder and fire-box, a series of fire-box chambers surrounding the muffle, and means for feeding ore to the muffle, of the ore and coal heating pipes, a series of pipes carried by the cylinder for inducting hot air into the muffle, and a series of pipes coupled to the coal-pipe for inducting coal into the fire-box.

PROCESS FOR RECOVERING SULPHUROUS OXID.—No. 829,765; Franklin R. Carpenter, Denver, Colorado.

The herein-described process of separating sulphurous oxid from furnace-gases, which consists in first separating from the furnace-gases dust or solid particles mechanically carried over from the furnace, refrigerating the gases thus cleaned to approximately 0° Centigrade to cause the sulphur-

ous oxid contained in the gases to be absorbed by the watery vapor therein and to be condensed or concentrated and deposited, separating the sulphurous oxid from the fixed gases and carrying off the fixed gases thus separated.

ORE-ROASTER.—No. 829,819; Ray E. Wickham, University, North Dakota.

An ore-roaster comprising a stand-pipe open at the bottom, tubes communicating with the interior of the stand-pipe for introducing from without the stand-pipe gas or liquid fuel, a hopper on the upper end of the stand-pipe, and having an outlet, a tube extended from the outlet end of the hopper and into said stand-pipe, and a feed-regulator.

MINER'S SAFETY AND OTHER INCLOSED PORTABLE LAMP.—No. 829,757; William Best, Morley, England.

A miner's safety or other inclosed portable lamp provided with a base portion or oil-chamber of annular or other form having a central conical aperture closed at the top by one or more glasses or lenses, said oil-chamber being provided with one or more wick-tubes protruding and projecting inward so as to bring their flame over the said glasses or lenses which allow the light of the lamp to pass downward through the conical aperture to beneath the lamp.

Mine Drainage Engineering.

By RICHARD C. WILLIAMS.

The reciprocating pumps of today have attained the limit of their efficiency and now the centrifugal type has been perfected until for some purpose it far surpasses that of the older style. This development in pumping practice has occurred only within the last ten years and that is the reason why the users of pumps have begun to realize the advantages and possibilities of the centrifugal pump. In the first place, the design of a reciprocating pump is such as to place it at the bottom of the list for mine drainage purposes, for no service is more exacting. The operator must supply a pump that will not eat up profits in cylinder repairs because of grit in the water, he must have a pump constructed so that the solids dissolved from the rock by the water will not cut the

The main idea of construction in the centrifugal pump is the most laudable any machine could have—only one moving part, the impeller. This secures freedom from wear; for what is desired, in mines particularly, is the ability to handle large particles of solid matter such as mud, sand, sticks, ore, and even fair sized stones, without in any way interfering with the operation. Moreover, the oil saved by the use of a centrifugal pump—instead of reciprocating—has sometimes paid the interest on the investment. It has also been proved in practice that the type is best for mine drainage, for with low heads the friction and eddy losses bear a high proportion to the energy expended in water pumped.

Without elaborating on those features of the design which do not concern the mine owner—but the engineer who constructs the machine—we will consider the reasons for the use of multi-stage turbine pumps. Why not use a single impeller of larger diameter and faster speed? Experience

indicates that such are not so economical of operation as the turbine-pump combinations. Imagine a main shaft 200 ft. deep, drained by two single centrifugal pumps, each capable of raising water 100 ft. and to save room and lost energy the exhaust of the lower pump is directly connected to the inlet of the upper, which forces the water on its last 100 ft. of travel toward the surface. But the friction and other losses due to not pumping the water in motion when once gotten under way in the first pump, and the added expense of two motor-units instead of one, caused engineers to ask, "Why not put both pumps side by side, mount the impellers on the same shaft, and have one motor, one attendant, and one installation instead of two, three, seven, or eight?"

Eight-Stage Centrifugal Pump in North Star Mine, California.

metal in a short time, and he wants a pump that is the most efficient in terms of power consumed.

How does the centrifugal pump work? Anyone who has ever held a pump-handle understands the reciprocating action, but possibly the centrifugal is an enigma to him. The same man when he was a boy amused himself with a stone or horse chestnut on the end of a string, whirling it around his finger until at the highest speed he let go and watched the missile shoot through the air. The law is that a body always tends to move in a straight line and if constrained to move in a curve it exerts a strain on the string or spoke, as in the case of a fly-wheel, which is proportional to the square of the revolutions per minute. This is why when the governor on an engine fails to work and the engine increases in speed it is not long before an enormous strain is placed on the metal in the fly-wheel. In the centrifugal pump the water is introduced near the centre of the rotor or impeller and by centrifugal force it is thrown toward the outside of the casing; the next portion of water thrown out forces portion number one up the pipe toward the surface. A centrifugal cannot be started without having the interior filled with water, for the strength of the action depends on the mass of the rotating body and the mass of air contained in the pump-casing is not sufficient when the pump is started to produce suction enough to draw in the much heavier water. The use of centrifugal action for moving air, however, is in familiar use in the fans used for ventilating, the centrifugal fan being in exact parallel with the pump, allowing for difference of construction to accommodate difference of material handled.

The turbine pump is not different in its action from a single pump, but by each impeller doing its share of the work on the water, the diameter and speeds of the rotors are kept within practical limits. But this combination introduces new problems. If the water be introduced on the same side of each impeller, an enormous end-thrust would result; so in the best pumps the water is admitted on one side of the first and on the opposite side of the next impeller. Owing to the high velocity of the water leaving the impeller, how can the velocity be transformed into pressure with the least loss? This is accomplished by means of a 'diffusion' ring—a scheme of nozzles, into the small end of which the water from the impeller is discharged. By passing into increasing cross-section, the velocity is lowered and the static pressure raised.

The question of leakage is one of mere mechanical detail which requires only good design and careful construction to compensate for, while that of water friction depends on surface wetted by contact with the water and change of direction of flow, and this requires great skill and experience both in design and construction. The efficiency obtained from centrifugal pumps varies from 60 to 80%. The eight-stage pump shown in the illustration was furnished by the Buffalo Forge Co., of Buffalo, N. Y., one of the largest builders of centrifugal pumps in the world, to the North Star mine at Grass Valley, Cal. This pump, under head of 1,400 ft., makes 1,800 r. p. m. and is driven by a 250-h.p. motor. The North Star Mining Co. is one of the most progressive in the United States; the mine has attained a depth of 4,600 ft. on the dip of the vein, this being equivalent to 1,800 ft. vertical

Sectional Mortar.

The accompanying illustration represents a sectional mortar for the standard five-stamp battery manufactured by the Colorado Iron Works Co., of Denver. It is especially suited for transport by means of pack-animals to mountainous regions too precipitous for other and better methods of conveyance. The vertical sections of the heavy base-plate are held together by four through-bolts, and all

the faces where the sections are joined are machine-planed so perfectly as to make a precise fit. This gives the mortar a neat symmetrical appearance when set up, making it as solid and serviceable as are those not sectionalized. The mortar is arranged for inside amalgamation, and a splash-plate may be attached to the lip if desired. No piece weighs more than 300 lb. In like manner, the entire milling plant may be built in similar sections where mule-back transportation is required.

Commercial Paragraphs.

THE BUTTE ENGINEERING & ELECTRIC Co., at 884-886 Folsom St., San Francisco, is making a specialty of equipping mines with hoists and electric appliances.

THE COMPRESSED AIR MACHINERY Co., of San Francisco, reports the sale of a 13 by 14 by 16 duplex Giant air-compressor to the Oriental Con. Mining Co., of Korea.

THE CHICAGO PNEUMATIC TOOL Co. reports the month of August to be the heaviest in the history of the organization, both in business booked and shipments made, the latter exceeding all previous monthly records, 15 per cent.

THE JOSHUA HENDY IRON WORKS has been incorporated with a capital stock of \$1,000,000 to take over the Joshua Hendy Machine Works. John H. Hendy is president and F. J. Behniman manager, with M. F. McGurn and Charles C. McGurn as directors. This incorporation takes place just 50 years after the formation of the original company.

THE UNITED IRON WORKS, Oakland, Cal., reports having received three first prizes at the Sacramento, Cal., State Fair for the best pump for mining purposes—the Eclipse step-pressure, the best water wheel—the Tuthill tangential, and the best general exhibit. It reports the sale of three French excavators and water wheel to the Suffolk Excavation Co., at Keystone, Wyoming.

CHAS. C. MOORE & Co., ENGINEERS, of 63 First St., San Francisco, is the first machinery house to be re-located at its old site. All temporary offices have been discontinued. The company is making a specialty of equipping and constructing complete milling and cyanide plants. It has now under construction a 50-stamp mill at Wadsworth, Nev., and a 100-stamp and a 60-stamp mill at Tonopah.

THE FOUNDATION COMPANY, of New York, has been awarded contract and is just about to begin work on the two mining shafts for Pickands, Mather & Co., of Duluth,

Minn. Both of these shafts are located at Biwabik, Minn. The owners encountered so many difficulties in attempting to reach the ore deposit and constructing a working shaft that they decided to contract with The Foundation Company for the construction of two shafts by the pneumatic caisson process.

Wm. A. Hewitt, of the HEWITT MACHINERY Co., of San Francisco, has just returned from an extended Eastern trip. While at Victor, Colorado, Mr. Hewitt was an interested observer of the machine-drilling contest recently held there between six makes of drills, and in which the Shaw drill was declared the winner. The Hewitt Machinery Co., at 503 Monadnock Bdg., San Francisco, is Pacific coast agent for the Shaw Eclipse air-hammer rock-drills and drill-sharpeners, and also for Blaisdell air-compressors, Jeffrey Badger rock-drills, Chalmers & Williams general mill and mining machinery, stamp-mills, Frue vanners, ore feeders, Kilbourne & Jacobs ore cars, skips and cages, steam and electric hoists, contractors' hoists and equipment, wood-working and iron-working tools, and boiler-makers' supplies. A large stock of the above machinery is *en route*. See their full-page advertisement on page 2 of this issue.

Trade Treatises.

THE TRAYLOR ENGINEERING Co., of New York City, has issued Catalogue No. 1, Stamp-milling Machinery. It is of convenient size and beautifully illustrated.

ALLIS-CHALMERS Co. has issued Bulletin 1,416 describing the Gates rock-breaker in its various forms and sizes. The sectional views in this pamphlet are superior, and show every working detail of these machines.

THE CHICAGO PNEUMATIC TOOL Co. has issued Catalogue XIX, a handsomely illustrated booklet, showing the varied uses of its pneumatic stone-cutting tools, from the sculpturing of the most delicate tracery in marble to the quarrying of gigantic blocks of stone.

THE JOSEPH DIXON CRUCIBLE Co., of Jersey City, N. J., has issued an interesting illustrated pamphlet, showing some of the noted ruins in San Francisco, where the Silica-Graphite paint, manufactured by this company, had been used, and which seems in a remarkable manner to have protected the surfaces over which it was spread.

A neat brochure has been issued by LACLEDE FIRE-BRICK MANUFACTURING Co., of St. Louis, Mo., descriptive of the refractory bauxite bricks made by them. It describes the results of a severe test made, extending throughout a year, in the kilns of the St. Louis Portland Cement Co. The data given are valuable to those using refractory furnace linings.

POWER AND MINING MACHINERY Co., of Cudahy, Wis., has issued one of the most attractive and valuable catalogues that has reached our desk this year. It treats of roasting, smelting and refining. It is magnificently illustrated, printed on superior paper, which makes the excellent halftones appear like original photographs. It is certainly a pleasure to look through a book of this kind, and no mining man can do so without feeling well paid for his trouble. It is catalogue No. 6, 'Roasting, Smelting and Refining.' Power and Machinery Co., Cudahy, Wisconsin.

L. VOGELSTEIN & Co., of New York, states that the German consumption of foreign copper for the period from January to July, 1906, was :

Imports of copper in July.....	8,163 tons	
Exports " " "	619 "	
Consumption " " "	7,544 "	
Imports of copper January to June.....	66,679 "	
" " " July.....	8,163 "	
Exports " " January to June.....	5,564 "	74,842 tons
" " " July.....	619 "	
		6,183 "
Consumption January to July.....		68,659 tons
Out of the above, 7,183 tons were imported from the United States.

Editorial.

THE TREMENDOUS industrial growth of the United States is suggested by the statistics of exports recently published. It appears that exports of iron and steel manufactures increased from a value of \$41,160,877 in 1896 to \$160,984,985 in 1906. During the same decade the export of copper manufactures jumped from \$19,720,104 to \$81,282,664. The grand total of exports was almost exactly doubled, from \$863,200,487 in 1896 to \$1,717,953,382 in 1906. These figures are eloquent of the growth of a country coterminous with a continent and wonderfully blessed in natural resources.

CALUMET & HECLA will soon have paid \$100,000,000 in dividends. The dividend of \$20 per share on 100,000 shares recently declared and payable on September 20, makes the grand total \$97,350,000. The lode of the Calumet & Hecla mine was discovered by Edwin J. Hulbert on September 17, 1864, the original Calumet Mining Company being organized two months later. The annual production of copper from this mine is now 43,000 tons of refined metal, worth about \$15,000,000.

AN Omaha paper prints an interesting account of the discovery of "a deposit of lava, from which a high-grade genuinely pure soap can be made." This deposit is situated near Orleans, in Nebraska. We congratulate the State of Nebraska; it can now wash its escutcheon clean and place upon it the motto: "While there is life there is soap."

THE SAN FRANCISCO POST-OFFICE has fallen on evil days. It is burdened with work beyond its normal capacity, and it is crippled for want of hands to deliver second-class mail. Seeing that the employees have to start with a stipend of \$50 per month, while almost any laborer—cleaning brick on the ruins, carrying the hod, or helping a carpenter—can get from \$3 to \$4 per day, it is no wonder that service under the Government fails to attract. Moreover, the business of the City has spread all over the residence area of the Western Addition, so that the Postmaster is expected to make frequent delivery of mail to outlying districts, as well as to the old business centre. Every influence is being brought on the Postmaster General to get these conditions alleviated, and, if the truth be known, the community that suffered so much from the earthquake-fire would be better aided by a proper postal service than in any other way. In the meantime the local officials are doing their very best and we ask our readers on the Bay shore to be patient. The poor service does not affect delivery to those at a distance.

ACCORDING to the official report the total area covered by mining leases in Japan amounts to two per cent of

the Japanese Empire, excepting Formosa and Saghalien. There has been a marked increase in mineral production, the value of the total output for 1905 amounting to 76,000,000 yen, an increase of 20,000,000 yen as compared to 1904. The mineral products exported had a value of 31,860,000 yen, an increase of 2,000,000 yen. Japan has jumped from sixth to fourth among the countries producing copper, her output representing five per cent of the world's production. As regards the value of coal produced, Japan ranks eighth but as regards tonnage she is equal to Germany and Austria-Hungary. In petroleum Japan equals India and takes the fifth place among countries. In sulphur, Japan is second and in antimony, third.

The Rights of Deputy Mineral Surveyors.

In response to an inquiry from Nevada, we published in the issue of August 18, page 197, our opinion as to the right of a Deputy Mineral Surveyor to locate a mining claim for himself. We are in receipt of letters denying the accuracy of this opinion, and several letters from Surveyors General and also some Land Office rulings are offered by those of dissenting mind in support of their contention that the Deputy Mineral Surveyor has no right to locate mining claims. The fact is, the United States Statutes are silent on this question, or, in other words, they do not say in terms that the Deputy Mineral Surveyor may not make a mineral location. The Land Office, however, has made several rulings, which are somewhat in conflict with each other. At one time it held that Deputy Mineral Surveyors were not prohibited from making mineral entries. Subsequently, another Secretary of the Interior decided that these officers came within the inhibition of Section 452 of the Revised Statutes and were prohibited from entering or becoming interested in any of the public lands of the United States. Still later decisions of the Land Office have a tendency in a direction somewhat contrary to the last. A case was decided by the State Supreme Court of Utah, in which the court held that a Deputy Mineral Surveyor was disqualified to make locations of mining claims. When this case was carried to the Supreme Court of the United States, that court gave no opinion on the subject. Until the matter is squarely presented to the Supreme Court, and it has rendered its unqualified opinion, the right of a Deputy Mineral Surveyor to locate mining claims must be considered at least a debatable question.

The tendency among most laymen is to belittle departmental rulings. This is wrong. It is a co-ordinate branch of the public service engaged in the monumental duty of administering the public land laws. It is aided as a rule by the best legal talent on the Attorney General's staff and is, and has been for a century, dealing with a complex system embracing all kinds of lands, construing all kinds of laws, many of which are themselves so ambiguous that their respective authors could not explain them without the necessity of explaining the explanation. Of course we occasionally encounter changed rulings and contradictory decisions, but this may be said of all human tribunals.

Too Much of a Good Thing.

In a letter from the City of Mexico which we published last week, a correspondent, who is a geologist and a mining engineer, spoke with feeling concerning the essential failure of the International Geological Congress, by reason of the excessive entertaining that marked the recent session in Mexico. If the truth be known, a similar story could be told of the majority of scientific and technical conventions nowadays. Hospitality is a generous fault, and when it is added to civic pride, there is no limit to the efforts made to entertain gatherings of distinguished men. Our friends in Mexico, for example, evidently did themselves proud, from President Diaz to the individual geologist who is helping to unravel the mysteries of rock structure on the great plateau of Tenochtitlan. But it is a kindness that defeats its purpose, for it attracts a number of the camp followers of science, dilettantes and globe trotters to whom the feast of reason and the flow of soul afford a nourishment less satisfactory than the viands of a banquet or the generous wine of a frequent toast. It is not wholly amusing to hear of courageous geologists who were unable to take their part in scientific discussions by reason of being put out of action by a combination of late hours, unwise wining and dining, the high altitude, and the languors of the tropics. But their experience is common to those who attend such congresses and conventions. Men travel from afar in order to meet their comrades in science, art, or industry, only to find that all the time needed for useful discussions, whether public or private, for comparing notes and interchanging ideas, is sacrificed to entertainments, to sight-seeing, to courtesies of which ladies form an essential feature, to grandiose speeches, and to the advertisement of the city or region in which the gathering is held. It is time the matter were faced squarely, for it is destroying the real purpose of such gatherings and will end in the abstention of the very men for whom they are organized, the while the merely sociable have "a good time." We shall run the risk of seeming ungallant by saying that, in the first place, the ladies are better at home. There is a lot of time given to courtesies that must be accorded to the gentler part of creation, there are entertainments for them in which most reasonable men are compelled to join, and, besides these distractions, many a thoughtful discussion is thrown off the track by the interruption of a feminine entrance, or the frou-frou of a silken exit. Men who could spend a useful hour in quiet chat concerning matters pertaining to their science or profession, find that whatever margin is left after official ceremonies, reading papers by title, long banquets, elaborate luncheons, and other unessential functions, has to be devoted to purely social amenities between their womenfolk. We would like to hear from our readers, for everyone goes to conventions of one kind or another, to Geological Congresses, Associations for the Advancement of Science, or Technical Societies. Shall we omit the ladies, most of the speechifying, most of the heavy dining, and bring the sight-seeing and festivity to a reasonable dose, so that we men, who want to know one another and swap yarns, can get together?

By the Way.

THE INSTITUTE IN ENGLAND.—From advance proofs of an unofficial sketch by Dr. R. W. Raymond, we quote the following interesting account of the doings of those members of the American Institute of Mining Engineers who attended the recent session in Europe:

Long before the day of meeting, it had become evident that the technical sessions provided for would give no adequate opportunity for the presentation and discussion of papers. To the "joint meeting," the Iron and Steel Institute furnished a considerable list of important contributions; and our Institute presented a still larger number, appropriate to the occasion. The president of each society read a presidential address, and some time was necessarily given to formal business. The total time which the overwhelming hospitality of our British brethren had left for technical sessions permitted one session of the Iron and Steel Institute, one of our Institute, and one to be divided between them. It may easily be inferred that little could be done in the way of reading papers. Even the little which the secretaries had expected to do was further diminished by unpremeditated discussions, etc. The room was crowded (about 600 members of the Iron and Steel Institute being in town); and everything favored discussion, except the lack of time. The sessions were highly interesting; the subjects presented were burning questions of modern practice; and those who, like myself, lamented the impracticability of a calm and leisurely interchange of views among the eminent authorities and captains of industry who were present, must comfort themselves with the reflection that the valuable essays prepared for this meeting would not have been written without such a stimulus, and that the valuable debates which did not take place in the hall at London will take place (are, indeed, already in progress) through the more deliberate process of correspondence and publication. The sessions were held in the stately hall of the Institution of Civil Engineers, on the walls of which hung the portraits of the past-presidents of that illustrious society. Some of them I had seen in life; for nearly fifty years ago, I had accompanied Sir Charles Fox to a meeting of the Institution of Civil Engineers, and had met there the famous Brunel, Scott Russell, and other great men in the profession. Now their faces were on the wall—and the grandson of one of them was shaking my hand in welcome.

H. R. H., the Prince of Wales, was for many years an Honorary Member of the Iron and Steel Institute and Edward, King of England, is now carried on its catalogue as 'Patron.' In view of the favor he had always shown to that society and its great work and purpose, the Council determined to confer upon him, this year, the Bessemer Gold Medal—which it had similarly given to Queen Victoria in 1899. The King having signified his acceptance, the ceremony took place at an audience given to a delegation of officers and past-officers of the two Institutes. On this occasion, the proceedings were perfectly informal. The King, in simple morning dress, without insignia of any kind, entered the room in which we were assembled; we were individually presented to him by President Hadfield; he shook hands with each of us, saying he was glad to see us (or words to that effect); Mr. Hadfield presented the medal with an address of perhaps a dozen lines, comprising one or two sentences; the King replied that he was happy to receive this token from the representatives of so important an industry; and the ceremony was over. Then His Majesty asked a few cordial questions of Mr. Hadfield, who told him in reply that his society was endeavoring to return to their American visitors some of the abundant hospitality it

had received on two occasions in the United States, at which the King nodded approval, intimating that he had experienced American hospitality himself, and added, "I suppose you will show them a little of this country, before you let them go home?" On being informed that we were to be taken to York, Middlesbro', Newcastle, Glasgow and Edinburgh, he expressed his satisfaction with that programme, and said, "I hope you will have a very pleasant time." A little later, remarking, "Well, gentlemen, I will bid you good afternoon," he departed as he had come, and we thereupon departed as we had come (to wit, in President Hadfield's splendid automobiles); and that was all. Nothing could have been more simple, hearty, and agreeable.

Seen thus at close quarters, King Edward appeared to be a stalwart, healthy, intelligent, and dignified and kindly gentleman; not needing to be pompous, in order to show himself great; completely at home in whatever circumstances, and instinctively able to put others similarly at ease; able to command without shouting, and to influence without either deceiving or dictating. And nothing is more striking than the absolute and universal unanimity with which all classes, denominations and parties in Great Britain hold, and declare this opinion of their sovereign.

ZEBULON PIKE.—In connection with the centennial celebration at Colorado Springs, it will be recalled that Z. M. Pike first saw the Rocky Mountains in November, 1806. The work done by this brilliant young soldier is worthy of the highest honor. He was in his twenties, a boy in years, when he made his two great journeys. He was only 34 when he was killed in battle, leading a charge against the British in the war of 1812. He had risen from the rank of lieutenant to brigadier-general, and no soldier in the country seemed to have a brighter future before him when he fell; but, had he lived, he might never have won prouder laurels than those which securely belong to him.

Pike's great opportunity came to him in 1805. The vast territory included in the Louisiana Purchase had been bought with the people's money, and the whole country was eager to know more about its new domain. Lewis and Clarke were sent by the President to traverse the great unknown in the Northwest. Pike was dispatched by the general in command of the army, first up the Mississippi to near its sources, and then up the Missouri and to the mountains in the heart of the continent. His expeditions were purely military in their organization. His companions were detailed from the army, and the strict discipline of their commander was one of the large factors in the great success he won. Here is an illustration of his discipline:

In January, 1807, Pike and his little party were near perishing hundreds of miles from succor among the Rockies. One day he heard a soldier remark, so that all might hear:

"It is more than human nature can bear to march three days without food through snow three feet deep, and to carry loads only fit for horses."

Pike waited till camp was pitched and then he called the men together and thanked them for their obedience, perseverance, and contempt of every danger.

"But, Brown," he went on, "you have presumed today to use seditious and mutinous language. This time I will pardon you, for I attribute your conduct rather to your distress than to an inclination to sow discontent. But I warn you that if you ever repeat such language you will be punished by instant death."

The special reports made by Pike on the information he collected were among the most valuable geographical documents of his time.

Special Correspondence.

Johannesburg, Transvaal.

A Boom in Diamond Mining.—Some Lucky Finds.—More Activity In Gold Stocks.—Re-patriation of Chinese.—Use of Steel for Shaft-Supports.—Working Cost at the Nigel Deep.

Tin has been dropped as the favorite horse of the "stock exchange race-course," and the gambling public has put its money on a new favorite, diamonds. For the sake of the diamond industry of South Africa, it is to be hoped that all of the diamond syndicates which have been floated will not be successful, for were they to turn out as many diamonds as the promoters expect to find, the precious stones would probably take the place of marbles and be used as toys by the children in the street. It is highly improbable that much will come of the gamble. One or two successful mines may be established. There has been much activity in diamond hunting on the Vaal river at a small place called Christiana. In this locality men have taken out licenses and some of them have been fairly lucky in finding the precious stones. During June the best find of any one digger was valued at £201, which comprised a stone of 35 carats, and 3½ carats of other stones, the result of treating 15 loads, which is a very handsome return. Many of the men were unlucky. One fellow who treated 150 loads got 1¼ carats, valued at £5 15s., and another got 35s. from 90 loads.

The record output for July seems to be the cause of the small boom in gold shares. Could the present conditions continue, and the present output be kept up, then the boom is justifiable; but when it is remembered that a number of mines may be forced to close down in a year's time, or to considerably reduce operations, one does not feel inclined to take part in the boom.

The excitement over State-aided re-patriation of the Chinese is cooling down, as it is seen that the vast majority of the coolies have decided not to go back. On some mines there is scarcely an application for re-patriation, while the largest number of applications on any one mine is 150. The first batch of re-patriates leaves shortly for China. After this no more will be able to go for several months, as there are no vessels sailing until next year. There should be peace now, so far as Chinese labor is concerned, until next year, when the elections begin.

The annual report of the Nigel Deep mine, in the Heidelberg district, shows how working costs mount up in this country, even with careful management, when the conditions are unfavorable. The working costs per ton crushed, for the past year, are as follows:

	s.	d.
Mining.....	25	10.113
Ore sorting and crushing	0	9.373
Ore transport	0	2.032
Milling expenses.....	3	10.253
Cyaniding sand.....	3	3.121
Cyaniding slime	1	1.400
General mining expenses	2	0.044
Mine office charges	1	5.511
Head office charges	0	7.016
London and Paris charges	0	6.765
Development redemption.....	7	4.312
Total cost per ton crushed.....	46	11.940
SUMMARY.		
Value of yield.....	52	3.178
Working costs	46	11.940
Profit per ton	5	3.238

Thus the profit is about 20% of the yield. This mine has a battery of 30 stamps. The reef is very narrow, and only hand labor is used in the stopes.

The Bonanza mine is dying hard. It was supposed to be nearly finished months ago, but for July it managed to show a profit of £5,960. This mine has already exceeded the original estimate of its life by about two

years—another proof that the estimates of the lives of the mines are conservative.—A novel scheme is recommended by E. J. Way, consulting engineer of the Rand Klipfontein mine, in the use of steel for shaft-timbering. He recommends steel instead of timber, on the following grounds: The cost of timbering works out at £6 per foot; steel works out at less than this; but taking them on an equal basis, if re-timbering had to be done twice in a life of 30 years, it would mean to this mine an extra cost of £48,000 besides the cost of delays, while steel suitably coated with an acid-resisting composition is considered to be good for the whole life of the mine.

London.

Another Mexican Exploration Company, Backed by Strong People.—Operations at Guanacevi and Tetela. — Splendid Returns From the Esperanza.—Oroville Dredging.—Cornish Tin.

From some particulars published today by Mexican Agency, Ltd., it would appear that the Agency intends to take a conspicuous part in opening up Mexico's national mineral deposits. The Agency itself has a capital of £350,000, of which £277,360 has been issued, and the remaining £72,640 is held in reserve. It operates under the influence and inspiration of the Esperanza and Camp Bird group. The managing directors of the company are Mr. A. M. Grenfell (chairman of Camp Bird, Ltd.), and Mr. J. S. P. Samborne (director of Esperanza, Ltd). The consulting engineer is Mr. R. J. Frecheville; the resident manager and the resident engineer in Mexico are respectively Mr. Richard H. Hutton and Mr. Louis Chevrillon. The Agency has acquired control of, or a large interest in, the Guanacevi Co., the Compania Minera de Mexico, and the Tetela Company. The Guanacevi properties comprise a large group of silver and gold mines in the camp of that name, as well as options on the extensions of the principal properties of the group. The most important mines are those of Santa Cruz, Aranena, San Vicente, and Mina de Agua; the other properties are old mines on what are said to be well-known veins, and will have to be cleaned out and re-opened before they can be properly examined. The sampling of the Santa Cruz orebodies has been thorough, and has been further confirmed by several mill-runs on large tonnage. It is estimated that the 120,000 tons of ore above mentioned should leave a minimum net profit of £90,000, reckoning silver at only 26½d. per ounce. The Aranena mine, which immediately adjoins the Santa Cruz mill, is stated to have an ore-shoot opened up and developed for a length of 1,200 ft., and has been worked in former times from the surface to 75 ft. below the present adit-level. Below this "the vein is virgin and the values are good." So far, this mine has only been worked for high-grade ores, which were sorted out. The San Vicente mine has continuous old workings for about three-quarters of a mile, with an uninterrupted line of dumps which have been sampled and found to contain low-grade ore. The Mina de Agua is another old mine from which quantities of rich ore have been extracted. It covers the immediate extension of the well-known Predilecta mine, which is stated to have produced £230,000 in the last few years. The Tetela properties comprise 69 claims in the camp of Tetela (State of Puebla) and an option on a group of claims on the extension of the main mine. The principal mine is that of Espejeras, said to have been worked for several hundred years, having been an important gold producer. At Huimantla, State of Guerrero, the company owns certain properties, which comprise 112 claims in the mining camp of Taxco, said to be the most important producer of the State of Guerrero. The claims cover a number of veins on which numerous old mines have been found.

The ores are all lead and silver. The properties on the Rio Balsas, in the State of Guerrero, cover large deposits of copper-bearing iron pyrite, low grade on the surface. They are being prospected in depth to discover whether enrichment takes place, as is the case with similar deposits worked in the same State which have developed into important mines. Another group of properties in the camp of Talea (Oaxaca) comprises 100 claims with important silver-bearing veins, some of which have yielded ores of a very high grade. One vein of this group has an average width of 27 ft., which can be followed on a length of over a mile, and at many points on the croppings has yielded ore very much above pay on a large part of its width.

Esperanza (Mexico) stockholders who have sold lately to below £3 on bear rumors will feel rather sick on seeing the August report from the mine published this morning. It is worth reading:

The mill ran 29 days and crushed 15,257 tons of dry ore.			
Shipped to smelter	8,628 tons of dry ore.		
Estimated realizable value of bullion produced		\$154,064	
Estimated realizable value of concentrate.....	79,500		
Estimated realizable value of ore shipped to smelter	634,252	\$867,816	
Receipts from rents and other sources.....		420	
		<hr/> \$868,236	
<i>Less</i> working expenses, including develop-			
ment, marketing of bullion, freight and			
treatment charges on ore shipped to			
smelter			
		\$327,840	
Allowance for depreciation of plant.....	2,500		
Consulting engineers' fees and New York of-			
fice expenses.....	2,526	\$332,866	
		<hr/> \$335,370	£109,707
<i>Less</i> London expenses of about.....			250
			<hr/>
Estimated profit			£109,457

Of this there has been expended on construction account \$2,383, and prospecting on Suceso property \$3,203. Feet of development work, 1,313. The report goes on to say: "As the attention of the directors has been called by shareholders to various adverse rumors which have been circulated with regard to the mine, I am instructed to inform you that such rumors are entirely without foundation. The lowest developments of the rich orebody continue to open up high-grade ore, while in the territory north of the fault, the San Rafael vein is opening up in a most encouraging manner on the 7th level."

El Oro returns for August show a good average: Tons milled, 22,231; yield, \$190,454; net profit, £17,591.

The latest news from Oroville Dredging, Ltd., is distinctly encouraging to English stockholders and American management. The net returns for the quarter, June, July, and August, are reported as approximately \$150,000, while the operating costs are stated to be materially reduced during that period. The gross returns during this quarter as announced weekly having been \$215,750, the operating cost works out at slightly over 30% thereof, and the net profit at the rate of over 17% per annum on the company's total capital with nine dredges only at work. It is announced that one of the three additional new dredges should be in operation before the end of the present month.

When capitalists and speculators return from the moors after their holiday they are promised a sheaf of prospectuses relating to Cornwall's hidden wealth, and the means to be employed by the use of their money to place some of these riches within their grasp. The last fortnightly black tin sale — 185 tons — shows a falling off in quantity, but the average price — £105 11s. 4d. — was an improvement of 14s. 7d. per ton on the previous 'tick-eting.'

Butte, Montana.

September Output. — Division of Property in Settlement Between Former Litigants.— The Nipper Goes to the Red Metal Co.— Anaconda Gets the Belmont and Will Sink Deep Shaft.— Settlement Releases Much Rich Mineral Territory.—East Butte Cuts Two Good Veins. —Pittsburgh & Montana to Resume Smelting.

The September copper production of the Butte district was 29,456,520 lb., 4,600,514 lb. less than in August, the decrease being due to the fact that there were two working days less in September than in August, and that four big mines—the Minnie Healey of the Red Metal, the West Colusa of the Boston & Montana, the Mountain Con. of the Anaconda, and the Clear Grit of the Washoe Co.— were not in operation during September, having been closed for repairs. The output of the lessees on the East Butte Co.'s mines was also considerably reduced owing to the fact that many of them have been engaged in opening new ground.

The different companies which contributed to the September production, in ore and copper, are as follows:

Company.	Tons of Ore.	Pounds of Copper.
Boston & Montana.....	96,000	7,296,000
Anaconda.....	111,000	7,992,000
Butte & Boston.....	18,300	1,281,000
Washoe	16,800	1,159,200
Parrot.....	11,160	691,920
Trenton	15,900	1,113,000
North Butte.....	30,000	3,900,000
Red Metal.....	28,500	2,080,500
Original.....	29,100	2,153,400
East Butte	3,750	337,500
Pittsburgh & Montana	4,020	402,000
Miscellaneous	15,000	1,050,000
Total	379,530	29,456,520

The daily output of ore and the average yield per ton in copper were as follows:

Company.	Tons of Ore.	Pounds per Ton.
Boston & Montana	3,200	76
Anaconda.....	3,700	72
Butte & Boston	610	70
Washoe	500	69
Parrot	372	62
Trenton	530	70
North Butte	1,000	130
Red Metal	950	73
Original	970	74
East Butte	125	90
Pittsburgh & Montana.....	134	100
Miscellaneous	500	70
Total	12,651	

The stockholders of the Red Metal and various Amalgamated sub-companies have completed the division of properties and orebodies in the settlement of the old controversy between the Amalgamated and F. A. Heinze, the predecessor in interest of the Red Metal Co. The latter, which is the operating company for the Butte Coalition, has secured an immense amount of mineral territory as a result of the compromise settlement, and the value of the mines of that company has thereby been increased more than threefold, compared with the value when owned by Heinze and disputed by the Amalgamated. In getting the Nipper mine, one of the properties that had for years been tied up by litigation and injunction, the Red Metal gets in value in that property alone almost as much as all the operated properties of Heinze were worth at the time he sold out to the Butte Coalition. The Nipper has always, by both sides to the litigation, been conceded to be an immensely rich property. It lies north of the Parrot and northwest of the Anaconda mine. The point in dispute between the Amalgamated and Heinze was whether the Nipper mine owned the apex of the vein on which Heinze was mining, the Amalgamated claiming it did not and therefore had no extra-lateral rights and could not mine beyond

the side-lines of the Nipper. The contrary view is evidently held in the settlement with Red Metal, for the latter is conceded the right to mine on the so-called Nipper or Blue vein on its dip beyond the south side-line of the Nipper claim and under the Odin, Kanuck, Adventure, Micawber, and one of the Parrot claims, all properties of the Parrot Co., and also under the western portion of the Never Sweat mining claim owned by the Anaconda Co. Its limits are, however, confined to the underground territory described, and from that point the vein will hereafter belong to the Parrot Co., which also obtains possession of some rich orebodies as a result of the settlement. The Red Metal also is given a five-thirty-sixths interest in the Nipper claim, which the Anaconda Co. had owned, and it now owns the Nipper absolutely. Heinze used to consider the Nipper one of the best copper mines in the Butte district and said it was capable of producing 1,000 tons of ore daily. The Red Metal will now proceed to operate the Nipper on a large scale. Through an arrangement, in anticipation of the settlement, the Parrot Co. has for some time been mining a limited area for the Red Metal Co. and hoisting the ore through the Parrot shaft.

In its settlement with the Anaconda Co., the Red Metal Co. deeded to the Anaconda several lots in the East Butte district, upon which is situated the shaft of the Belmont mine, a former Heinze property. The Anaconda intends to enlarge the shaft and sink it to a depth of several thousand feet, and make it the main working shaft for the Anaconda mines, the southerly workings on the big Anaconda vein being near the Belmont shaft. The Red Metal owned an interest in the Dayton mine, which has been transferred to the Boston & Montana Co., and the latter in turn made a number of important concessions in settling the controversies over the orebodies of the Minnie Healey, Pennsylvania, Gambetta, Piccolo, and Colusa mines. The orebodies in these properties have been divided along certain planes and levels of the underground workings, to which the operations of each company will hereafter be confined. The settlement releases immense orebodies which for years had been tied up by injunction, and the Red Metal Co. thereby acquires a large mineral territory. The settlement between the Red Metal and Butte & Boston releases to the latter the veins in the Michael Davitt mine, while the Snohomish and Tramway mines, in which both companies own interests, will be operated jointly by the two, each sharing in the profits and expenditures in proportion to the interests owned in the property.

Since the Red Metal came into possession of the Heinze properties an immense amount of work has been done in repairing the properties, which had been worked hastily as the time approached for turning them over to the new company, and were left in a bad condition. In prosecuting the work new orebodies have been opened up in the Minnie Healey, Rarus, and Corra mines, and with the Nipper in commission again, the Red Metal will soon be in position to mine from 2,000 to 3,000 tons of ore daily.

The East Butte Mining Co. has cut two large veins in the 400-ft. cross-cut, one north of the shaft and the other to the south. The veins are two of those being worked by lessees between the 200-ft. level and the surface. At the 400 they are larger and richer, which appears to indicate persistence to greater depth. The cross-cut will be continued north and south through the entire width of the company's original ground, and at least twenty veins will be cut. The vein north of the shaft is about eight feet wide and carries four feet of first-class ore, the remainder being good concentrating stuff. The first class runs about 8 to 10% copper. The vein cut south of the shaft is larger, and much of the ore runs as high as 40%

copper. The company will begin mining on its own account within a few weeks.

The Pittsburgh & Montana Co. is hoisting about 135 tons daily; it is the richest ore yet taken out of the Pitts-mont ground, the average for August having been 6.15% copper. The mines are opened to a depth of 1,200 ft., but it is hoped that the best orebodies lie deeper, and a winze is being sunk from the 1,200 level. The company is also engaged in running a cross-cut north through the length of property. Three drifts are also being run on the veins. The Pittsburgh & Montana Co. is likely to begin remodeling its smelter soon, and resume treating its own ore. It has been estimated that the smelter can be re-built and made into a modern plant with the expenditure of an additional \$50,000. It will be necessary to abandon some of the Baggaley appliances, which have proved so expensive to the company while the inventor was experimenting with them. Some of them have proved practical and will be retained. If the smelter is re-modeled the company will treat some custom ore, and will probably handle that of the East Butte Company.

Denver, Colorado.

Oldest Mines at Cripple Creek Still Productive.—Lack of Cheap Milling.—Saratoga Smelter Starts to Work.—The Discovery in Poughkeepsie Gulch.—Disaster to a Power-Plant.

The Gold King in Poverty gulch, Cripple Creek, was the first mine in the district to ship ore. The ore was actually struck in the Gold King, then called the Chance claim, in February, 1891, but the first shipment was made early in 1893. The mine is still shipping. About one carload per week of high-grade ore is marketed. This ore comes, very largely, from the 1,000-ft. level. In 1902 the cry was raised that the Cripple Creek mines were all surface pockets and that the camp was nearly worked out. The writer was one of the very few who contradicted this idea in print and the MINING AND SCIENTIFIC PRESS was one of the few technical journals that voiced the same ideas, so it is gratifying to notice the record of such mines and say, "I told you so." There are, of course, many others that are making heavy productions from even greater depths than the Gold King. Take the camp as a whole and it is doing nicely, but it needs two things very badly: One is a deeper drainage adit to facilitate the working of the (now well established) deep-seated ores, and it needs lower milling costs for its low-grade ores. It is remarkable that an American mining camp in an enterprising Western community should struggle along under a handicap which is unwarranted and burdensome. This is the more remarkable when it is considered that Cripple Creek men have gone abroad and overcome greater milling difficulties in other camps. Take Kalgoorlie, Western Australia, for instance. Robert J. Grant and H. A. Shipman, both of Cripple Creek, were the pioneers in reducing milling costs to a reasonable basis in that camp. Shipman and Grant got their milling costs down to about \$3 per ton on telluride ores, and the working conditions at Kalgoorlie are less favorable to economical operation than they are at Cripple Creek. Still Cripple Creek cringes along in the shadow of the 'Trust' to the tune of about \$7 per ton as a minimum rate on her low-grade tellurides.

Elmer E. Loring, manager of the Hoosier Creek Gold Mining Co., is about to unwater and prospect the lower workings of the famous old Hoosier mine, on Hoosier Pass, at the headwaters of the Blue river. This property is located on a large vein of low-grade stuff. The principal value is in gold. It is probable that a modern mill will be required to work the mine at a profit.

The old Saratoga smelter at Ironton has resumed

operations after a period of idleness of at least twelve years. For several years the late Charles Newman, of Durango, tried to interest capital in the enormous low-grade iron-gold orebodies near Ironton. Last year he died. Now his dream is being realized, but by others. Just as the grim and silent stacks of the old smelter seemed to brood like a disembodied spirit over the period of Ironton's neglect and desolation, so we can imagine the cheerful spirit of Charles Newman brooding over the newly born period of her activity and prosperity. The old smelter was unable to do what the modern smelter can do, and the old promoter failed at the task that younger and brighter men have carried through with ease.

Another old San Juan property to resume operations is the Neodesha in the Bachelor district. It has been leased by the Arps Bros., of Ouray, and almost at once, after taking hold, they began to ship ore. The regularity with which lessees begin to ship ore from old and neglected properties, almost as soon as they go to work, is remarkable.—The recent sensational strike of free gold ore in Poughkeepsie gulch above Ouray, in the San Juan range, continues to excite wide-spread interest. The gold values have been traced along the vein for 1½ miles. The first claim located on this vein was called the Free Gold and the whole vein is generally called by that name. Thomas Walsh, former owner of the Camp Bird, has been down to see it.

The recent disaster to the Rockwood Power Co. plant below Silverton may be studied with profit by owners of other power-plants. There was a small leak in the main delivery-pipe some 300 ft. above the power-house. This leak did not amount to anything at all so far as the loss of water was concerned, and it was neglected. The little jet of water issuing from this leak gradually undermined the supports of the pipe for a considerable distance and the pipe sagged and broke. The water liberated under pressure did great damage, washing a large amount of soil down on top of the power-house and undermining the pipe-line still further.

The annual report of the United States Reduction & Refining Co. for the year ended July 31 shows a surplus, after charges and preferred dividends, of \$176,704, an increase of \$115,336. Four quarterly dividends were paid on the preferred stock, aggregating \$236,748. According to the report of the executive committee, the tonnage of ore produced in the Cripple Creek district during the year was greater than at any time since the labor troubles in 1903. The sale of the Utah Copper Co.'s stock was consummated after the close of the books for the last fiscal year. The initial plant which was erected for treating one of the tailing dumps at Colorado City, has continued to be successful and profitable. During the early part of the present fiscal year an experimental plant was erected and operated to determine if still further values could not be recovered from the tailing. These experiments were satisfactory and the directors authorized the construction of a tailing plant to treat 800 tons per day, including the daily discharge from the mill. This plant is rapidly nearing completion and will be finished in the latter part of October. At the time of the annual meeting in January, 1907, we hope to be able to give definite figures as to the results, which will enable the directors to decide as to the advisability of erecting a similar plant at Florence. The general balance sheet shows a net surplus of \$1,620,209. Cash, accounts receivable, and advances on ore total \$690,165.

Already Denver is preparing to welcome the American Mining Congress which meets here on October 16. There seems little doubt but that this meeting will be a great success and many representative mining men from all

over the United States are coming to attend the Congress. Vice-president Fairbanks has just been entertained in Denver. The vice-president has an ingratiating way about him and has made a host of friends in this vicinity. He tells an audience that they have the finest city and State on earth and does it in such a trust-inspiring way that people forget that he said the very same thing in the last city and State he visited.

Toronto, Canada.

Preparing for Winter at Cobalt.—Another Strike in the Nipissing.—Other Discoveries of Rich Silver Ore.—Government Mining on the Timber Lands.—A New Recorder's Office.—Gold and Iron Ores at Steel River.—Asbestos Industry.—Head Bounties.

With the near approach of cold weather, which sets in earlier in New Ontario than in the southern portion of the Province, preparations are being made for the winter. Numerous new buildings are being put up and all arrangements made to permit work to continue without interruption. Production of ore has lately been steady, most of it being stored until the smelters in course of erection at Hamilton and Trout Lake are ready to handle it. The terms offered by the Copper Cliff smelter at Sudbury, Ontario, are hardly more satisfactory than those of the New Jersey smelter. While the Copper Cliff smelter pays at the rate of 50c. per lb. for the cobalt content of the ore, it only allows 90% for the silver, as against 95% paid by the New Jersey smelter, which allows nothing for cobalt. The quantity of ore packed ready for shipment at the leading mines amounts to about 20 carloads, mostly high-grade, running from 1,500 to 3,000 oz. per ton.

Another discovery has been made on the Nipissing property about 250 ft. south of the vein at Ledge 49—consist of a vein 10 in. wide on the surface, which has been uncovered for a distance of 50 ft. and yields an assay of 50% silver. Should this vein prove to be a continuation of Ledge 49, as there is reason to suppose, the deposit will be an extremely valuable one. At the McKinley-Daragh-Savage mine a new vein has been struck in the 75-ft. cross-cut at No. 1 shaft, from 6 to 8 in. wide and carrying plate and leaf silver. No. 2 vein has been stripped for 400 ft., and is found to improve in value as it is followed downward, assays showing silver up to 3,000 oz. per ton. The Kerr Lake Mining Co. is working seven veins on its property, the ore averaging from \$1,200 to \$1,600 per ton. During August the shipments from this mine were over 60 tons, valued approximately at \$90,000.

At the Ontario Government mine on the Gillies timber limit, the work of sinking the shaft is making steady progress under the direction of the Inspector of Mines, Mr. Corkill. It has been decided to conduct mining operations directly by the Government through the Bureau of Mines and not by contract, and it is intended to ship a carload of ore to the smelter this fall to raise money for the work instead of drawing upon Government funds, thus making the enterprise self-sustaining from the outset.

The Wabi Cobalt Mining Co. has made a strike on its location on Lot 11 in the fifth concession of Lorraine township, east of Cobalt. At a depth of 12 ft. in the shaft, a cavity about 8 ft. deep was discovered, the dirt in which was rich in native silver, assays of which, when panned out showed 13,410 oz. per ton.—The new recording office in Cobalt was opened last week, and is doing a big business in prospectors' licenses.

E. F. Beattie, of Bay City, Mich., president of the Argenteuil Iron Mining & Milling Co., has secured a valuable gold, iron, and silver location at Steele river on Lake Superior, about 155 miles east of Port Arthur. The

gold and iron veins run parallel from the water's edge up a cliff 110 ft. high. The gold vein is claimed to be 100 ft. wide on the top of the cliff, and of unknown depth; the ore is arsenical pyrite carrying free gold and some silver. The iron is hematite, running about 50% iron. Analyses of two of the samples of gold ore give returns of \$325 and \$37.60 per ton. Mr. Beattie obtained information as to these deposits from a fisherman at Jackfish, who was told of them by an Indian.—The Golden Park Mining Co., of which J. W. Keenan is general manager, is preparing to begin extensive mining operations on the McPhail property near Dryden, Ont.—The Viking gold mine, Eagle Lake district, has been acquired by the Viking Gold Mining Co., the stock of which is largely held by Toledo, Ohio, capitalists who are resuming work on the property.

The Philip Carey Manufacturing Co., which has a large plant at Cincinnati for the manufacture of asbestos goods, is establishing a branch near Montreal, the object being to save the 25% duty on raw asbestos imposed by the American tariff.—The Canadian lead bounties have been suspended for some time, under the provision of the law that no bonus is to be paid when the price exceeds £16 10s. per ton. Advices received by the Trade & Commerce Department give the current market price of lead on the London market at £18 per ton, so that the bonus continues suspended.

Bisbee, Arizona.

An Important Transfer.—News From the Big Mines.—Fresh Discoveries of Ore in the Calumet & Pittsburg and Shattuck-Arizona.

Information has come from a reliable source that the details in connection with the turning over of the Warren Realty & Development Co. to the Cole interests are being arranged at Duluth, Minn., at the present time. The nature of the transfer seems to be that the property will come directly under the supervision of Thos. F. Cole, whereas formerly he took no active part in the management of this enterprise.

At the Copper Queen everything is about the same as usual. Progress is being made in the erection of the new machine-shops on the side of Sacramento hill, and a good wagon-road has just been completed, connecting the Gardiner and Lowell shafts. At the Calumet & Arizona smelter everything is running along smoothly, and the output will equal that of last month, namely, 4,600,000 lb. copper. An additional blower and engine have been contracted for, and will be delivered before the first of the year. The output of the Copper Queen smelter will also equal that of August. At the Superior & Pittsburg property the water in the Briggs and Hoatson shafts has increased materially during the week, but with the pumping facilities available, it will be an easy matter to take care of the increased flow. At the Briggs, ore of an excellent grade was encountered during the week, in the drift which is being driven from the C & P shaft to the Hoatson. A stringer of ore several feet in thickness was encountered during the early part of the week and it is still in evidence. At the Hoatson, a large quantity of ore is being hoisted, but on account of lack of facilities for loading railroad cars at this shaft, the ore is being placed temporarily on the dump. The management intends to start the construction of ore-bins this week, and as soon as they are completed shipping will probably begin from this shaft. Several high-grade orebodies were encountered in this shaft during the week, and the outlook is highly satisfactory.

At the Shattuck-Arizona, the new Allis-Chalmers hoist, which was ordered some months ago, arrived during the week, and is being hauled to the property. This plant will be installed and operating within the next three

weeks, at which time the hoist borrowed from the Junction will be returned, and ore shipments materially increased. The Sullivan compressor will not be shipped until early in December. The two new 150-h.p. boilers have been placed in position, and as soon as the old ones can be re-arranged a new boiler-room will be constructed. The ore shipments have been averaging a little less than 200 tons per day, but it is expected that this will be increased to 300. On the 700-ft. level two new bodies of sulphide ore is being opened up, as well as one of oxidized material. On the 800 a new sulphide body was encountered on Wednesday. The drift on the 600 is in iron ore and lode-matter. Sinking of the shaft will be resumed this week and will be continued until the 900-ft. mark is reached; the shaft at the present time is down 800 ft. At the Denn-Arizona property, everything is going along about the same as usual. At the Cochise, the shaft is being sunk and the water is saturated with copper.

Cripple Creek, Colorado.

A Destructive Fire.—Successful Lessees.—A Patentee Wins His Suit Against the Portland.—The Gold Sovereign Highly Productive.—Sale of the Dillon Mine.—A Deep Shaft for the Dexter.

The entire surface plant of the Jerry Johnson Mining Co. on Ironclad hill was destroyed by fire the night of September 24. H. P. Dahl has this property under lease and he estimates the loss at about \$10,000, with little or no insurance. The origin of the fire is not known. The compressor on this property supplied air to the Teutonic, W. P. H., Arapahoe, and Midway, and its being put out of business will materially affect these properties.—The Union Leasing Co., operating the Proper claim, Block 108 of the Stratton Estate, on Bull hill, has installed an electric hoist. Cross-cuts will be started from the bottom of the shaft, which is 100 ft. deep.—A small car of rich ore has been shipped by John Davis, leasing on the Doctor-Jack Pot mine on Raven hill. Work is being conducted through the Morning Glory shaft. The returns from this small lot ran 15 oz. per ton and another larger shipment is expected to be made shortly.—On the north end of the W. H. P. claim on Ironclad hill, Sorrenson and associated lessees have recently cut ore at a depth of 175 ft. Machinery is being installed, so as to be able to sink the shaft another 100-ft. lift and cut this orebody at a greater depth.

Not long ago F. Herrman brought suit against the Portland Gold Mining Co. for infringement of his patent rights. Herrman invented an ore-washing machine, which he claimed the Portland Co. had been using without his consent, and damages were awarded him. The Portland appealed the case to the Federal Court, but a new trial was denied.—Beebe & Large, operating the W. P. H. lease of the late United Gold Mines Co., are shipping good grade ore from the 400-ft. level, which is expected to run in the neighborhood of \$50 per ton.—It is possible that when the Golden Cycle mill at Colorado City is in full working order, the output of the Gold Sovereign mine on Bull hill will be sent to that plant for treatment. This mine produces between 1,000 and 1,500 tons of ore per month, which is obtained from one of the largest ore-shoots in the district.—The first dividend of the year of half a cent per share, amounting to \$12,000, has been declared by the Gold Dollar Mining Co., on Beacon hill. Payments will be made on October 15.

The Dillon property on Battle mountain, which was until lately under lease to Waters & Price, has been bought by the Granite Gold Mining Co., whose property adjoins the Dillon on the west. The sale price is in the neighborhood of \$160,000. The Dillon Co. owns the Dillon and Amazett claims, which produced \$87,000 in 1905. The main shaft is down 800 ft. and the Granite people

intend to sink it still further right away, as well as to do other development work.—Extensive development of the Dexter mine, situated on the east slope of Bull hill, and the Empire State, of the Isabella Gold Mining Co., on the north slope of the same hill, will shortly take place. W. E. Little and partners have these two mines under lease, and \$80,000 has lately been raised among Eastern capitalists. It is proposed to sink the Dexter shaft several hundred feet, making it one of the deepest in the camp.

Negotiations are pending for the Golden Cycle mill to treat the ore from the Abe Lincoln mine of the Tunnel & Leasing Co. The ore of this mine is being stored awaiting results.—The Standard Leasing Co., operating on the South Burns property on Bull hill, has been getting some very good ore in the last few days. Stoping is being carried on at the 800-ft. level, west of the shaft on a vein five feet wide. Cross-cutting has also been going on for some time to catch the Findley vein, which was cut last week. Work on this vein has already begun and the output of the mine should materially increase from this source.—A. T. Holman, general superintendent of the Golden Cycle Mining & Milling Co., has resigned his position and Joseph Carr, foreman of the property has taken his place.

The Dollar Leasing Co. has been formed by Jesse Waters, J. J. Cogan and J. W. Price, to operate the Last Dollar mine on Bull hill, the articles of incorporation having been filed with the county clerk and recorder. The directors comprise, in addition to the above men, B. H. Hopkins and George F. Fry, and the company will be capitalized for \$10,000, the shares having a par value of \$1.—The Shurtloff mine on Bull hill, belonging to the Findley Mining Co., is to be started up again within the next few days. A large quantity of ore has been blocked out on both these properties; enough, it is said, to keep three shifts going for a year or more.—Ore is being mined and hoisted from the fifth, eighth and ninth levels on the Wild Horse mine, on Bull hill, by Cavanaugh & Co., lessees. The filling of the vats of the cyanide mill on the same property has begun, the ore being treated at the rate of 35 tons per day.

Salt Lake, Utah.

Shortage of Coal at the Smelters.—Dividends from Utah Mines.—Labor Supply at Ely.—Repairs to the Ontario Adit.—Stock Transactions.—The Output from Tintic.

A shortage of coal is seriously handicapping the operation of the smelters in the Salt Lake valley at the present time and the supply on hand is becoming so dangerously low that grave fears of a shut-down are entertained. This situation is said to be due to the physical inability of the railroads to handle the traffic with their present equipment; in other words, the transportation companies have not kept pace with the prosperous condition of the country and are short on rolling stock. It is almost impossible to get slack coal at all and the smelting companies are compelled to content themselves with whatever they can get. The big mill of the Consolidated Mercur Co. at Mercur exhausted its supply one day last week, and it was out of commission for a brief period. The diverting of cars to the beet fields of Utah and Idaho is one of the causes of the coal famine.

Twelve Utah mines paid dividends during the month of September; the list consists of the following: Mammoth, \$20,000; Bullion Beck, \$10,000; Carisa, \$5,000; Grand Central, \$15,000; Victoria, \$10,000; Swansea, \$5,000; Uncle Sam Con., \$5,000; Utah (Fish Springs), \$3,000; Silver King, \$50,000; Consolidated Mercur, \$25,000, and Daly-West, \$108,000. The two last named made their regular quarterly distributions. The Sacra-

mento Gold Mining Co. resumed payments on October 1 with \$5,000.

There has been an exodus of laborers to Ely, Nevada, but an official of the American Smelting & Refining Co., which controls the Nevada Consolidated, states that it will be several months yet before the latter will do much construction and therefore the demand is well supplied. Now that the Nevada Northern railroad is completed, however, contracts will be awarded without delay for material and equipment for the new concentrating mill and smelter, the former to have a capacity of 5,000 tons of ore per day. Mr. Karl Eilers, member of the executive committee of the A. S. & R. Co., who had personal direction of the construction of the Garfield smelter here, has gone to New York to remain indefinitely and will supervise the letting of contracts for the Ely plants. The Ely Con. Copper Co. has been launched here to operate at Ely. Walter G. Filer is president and Willard F. Snyder, vice-president, both of Salt Lake.—The deal pending for a consolidation of the Silver Shield and United Bingham mines at Bingham has fallen through.—The Little Bell mine at Park City was closed last week.

Ore shipments from the Park City mines last week amounted to about 2,600 tons, the shippers and amounts being: Daly-Judge, 926; Silver King, 573; Daly-West, 625; Little Bell, 279; Ontario, 107; Keith-Kearns, 61; New York Bonanza, 18; Jupiter, 16. The new hoisting plant ordered for the Magnolia-St. Louis mine is being installed. The great task of re-opening the Ontario drainage adit, which caved in two years ago, is progressing and the main avenue will soon be tapped by the drift run around the portion that caved. To ensure safety a cement bulkhead has been put in at a distance from the portal of the adit of 14,000 ft. in a formation of solid rock. The bulkhead is 10 ft. long and 4 ft. high, and contains nearly fifty pipes, ranging in size from 2 to 4 in., each fitted with valves, so that the flow of water can be controlled as desired. The door to the bulkhead is a massive piece of iron, 3½ ft. wide, 4 ft. high, and 17 in. thick, weighing over two tons. It is swung on three hinges so adjusted that the door will be closed by an unusual flow of water.

The ore and bullion settlements reported by Salt Lake banks during September aggregated over \$2,000,000, while the sales on the Salt Lake Stock & Mining Exchange during the same period amounted to 1,662,196 shares, for which \$882,632 was paid.—The annual meeting of the New Stockton Mining Co., operating at Stockton, resulted in the retention of the board of directors elected a year ago. J. J. Trenam, of Salt Lake, is manager.

The ore shipments from the Tintic mining district last week were 123 carloads, the different mines contributing as follows: Beck Tunnel, 7; Bullion-Beck, 7; Carisa, 4; Centennial Eureka, 30; Dragon Iron, 9; Eagle & Blue Bell, 4; Eureka Hill, 7; Gemini, 4; Godiva, 2; Grand Central, 9; Lower Mammoth, 4; Mammoth, 15; Ridge & Valley, 2; May Day, 1; Scranton, 4; Swansea, 2; Uncle Sam Con., 4; Victoria, 6; Yankee Con., 2 carloads of ore.—The plant of the Utah Smelting Co., near Ogden, is practically completed and a contract has been made to bring power from Brigham City.—Walter C. Orem, manager of the Nevada Douglas Copper Co., operating near Yerington, Nevada, has returned after concluding a contract with the Truckee Electric Power Co., whereby the latter will supply the Douglas mine and proposed reduction works with electrical energy for a period of ten years. Mr. Orem will place contracts for heavy mine equipment. The Nevada Douglas appears to be a copper property of some magnitude, and the company has been strongly financed. The head office is in the Auerbach block, in Salt Lake City.

Mining Summary.

ALASKA.

The first men from the Chandlar strike report that the camp will probably be one of the best in Alaska. Joe McGuire and four other old-time Klondikers who arrived say 250 Koyukuk men have staked all the best creeks and will remain in the district this winter. Food has to be hauled over the ice, 150 miles from Yukon or Miles, or over snow from Coldfoot. Frank Howard, recorder from Koyukuk, has opened an office and is personally in charge of Chandlar camp. A man named McNett is the discoverer. The creeks carrying gold head from the high dome between the North and Middle forks of the Chandlar. The best known creeks are Squaw, Little Squaw, Rock, McMillan, and Big. Some flow into the North Fork and some into the Middle. —Big and Squaw are the richest so far. Pay was found running from five cents to four dollars per pan. Stampeders are on the way from Rampart and other camps. Fifteen men from Rampart who arrived from Fort Yukon went up the Chandlar immediately in small boats. Supplies at Fort Yukon are limited and the prices twice those at Dawson. —McGuire and partners are emphatic that no one should go to the new camp without being prepared for winter.

ARIZONA.

The old and abandoned Queen mine, in Superior district, is to be re-opened and worked as soon as the new owners can get matters properly arranged. The new company at the head of the enterprise is composed of W. D. Fish, J. H. Thompson, J. W. Banbauer, Richard Fleming, and J. S. Towle, all of whom are Globe men. The company has incorporated under the name of the Queen Copper Mining Co. The authorized amount of capital is to be \$5,000,000, divided into 5,000,000 shares at a par value of one dollar per share. The life of the company is to be 25 years, and its principal place of business is Superior, in Pinal county. —The Pinkham mine at Chloride, in Mohave county, is producing more than a carload of ore daily.

COCHISE COUNTY.

Work has been commenced on the new railroad from Dragon Summit to Johnson camp. The road will be five miles long. The Johnson Development Co., under the management of Kirk Hart, is sinking a double-compartment shaft. It is now down over 200 ft. The company uses a 25-h.p. gasoline hoist which gives satisfaction and has led others in the district to install them. At the Old Peabody, under the direction of H. J. Clifford, regular shipments are being made to the Copper Queen smelters at Douglas.

The Parks property, a group of four claims, has recently been bonded to Douglas Gray, of El Paso, and F. M. Hartman, of Tucson. —The Empire Co. is in 500 ft., and expects to make connections with the other workings within a short time. —The Arizona-Michigan Co. is down 100 ft. in its shaft. —The Arizona Consolidated, under the management of S. T. Entrekin, is making regular shipments to El Paso smelters.

The legality of the action of the Territorial Board of Equalization in raising the assessment on the mining property in Cochise county 400% is to be fought in the courts. The attorneys for the Copper Queen Co., with others, are getting data, and the matter will be brought to the attention of the courts at once. The case will be made a test one and will not apply to any particular mine, but will cover every patented mining claim in the country that was affected by the raise. The action of the Territorial Board last year was declared by the Supreme Court to be illegal, and the court will again have a chance to say whether the action this year was legal or not. The action of the Territorial Board this year was done in the manner prescribed by Attorney-General Clark as he interpreted the rulings made by the Supreme Court in its decision in the cases of last year.

YAVAPAI COUNTY.

(Special Correspondence).—Grading and excavating for the new mill to be erected on the Gold Leaf and Snowshoe

mines, in the Cherry Creek district, is now finished, the machinery for the mill has been purchased and is now on its way to the camp. The power in the mill will be furnished by a Pelton water-wheel. The mill purchased is of the Lloyd patent grinding stamp pattern. There is an excellent showing of ore in the Gold Leaf mine. Work was discontinued in the mine lately on account of water, and it is the intention of the management to install a hoist and pumping plant as soon as the mill is completed and the work of sinking the shaft to a greater depth resumed.

Work is being pushed on El Capitan mine, in Kirkland district. The new shaft is now down 60 ft., where there is an excellent showing of ore. One of the two parallel locations covers a spring with a good supply of pure water, sufficient for the domestic uses at the company's camp, which is four miles south of Kirkland, on the S. F. P. & P., which can be easily reached by a good wagon-road.

Phoenix, September 28.

CALIFORNIA.

ELDORADO COUNTY.

The Standard Unit mill in Coloma canyon, near Garden Valley, has been started under the direction of John Moore. —Work is to be resumed at La Graves mine, near Garden Valley.

NEVADA COUNTY.

E. B. Whitehead & Co. have bought 600 acres at Deadman's Flat, near Grass Valley, and propose sinking a two-compartment shaft to develop veins discovered by previous prospecting.

SIERRA COUNTY.

Miners' wages at the Sierra Butte mines at Sierra City have been raised to \$3 per day, less 75c. for board, which is furnished by the company. —Good progress is being made in the construction of a 20-stamp mill at the Hayes Consolidated mine. —The adit of the South Fork gravel mine at Forest City is in 4,360 feet.

TUOLUMNE COUNTY.

(Special Correspondence).—The work of cleaning and re-timbering the double-compartment shaft of the North Star mine is nearly finished. Within a few days work on the north drift at the 200-ft. level, which is 50 ft. long, will begin. The force is soon to be increased and three shifts will be worked instead of two as at present. A building to shelter the hoist will be erected. —The 5-stamp mill, hoist, and other machinery comprising the equipment of the Prudhomme mine have been moved to the Mary mine, the property of the Mountain Mining Co., situated two miles north of Tuolumne. W. A. Monroe, the superintendent, has developed the property satisfactorily and the outlook is said to be decidedly good. —Machinery to facilitate development work has been purchased by Glen & McKenney for their property on Knight's creek, in the Columbia district. —Work preparatory to the erection of the 60-stamp mill to be built by the United Mines Corporation on its property near Tuolumne is progressing well. The grading required several weeks to complete. All is now about ready for the actual construction of the mill. In the group owned by the United Mines Corporation are the Grizzly, New Albany, Dead Horse, and Lady Washington mines.

Tuolumne, October 1.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—Since the recent rise in the price of silver many mines which have lain idle for years are being re-opened. —Work has been started on the Sol Reynolds group on Griffith mountain, above Georgetown, by W. T. Nixon and partners of Denver. —W. C. Hood and F. A. Maxwell have resumed work in the Housborough adit to exploit more thoroughly their seven claims on Democrat mountain. Some good ore was shipped from this property in former years. —The Prudential Mining Co. is driving west on the two veins cut at 650 and 700 ft. respectively in the Prudential adit which enters the base of Republican mountain. The company is also driving the Montgomery-Ward adit, 2,000 ft. higher up the mountain on a line with the Prudential. —H. B. Clifford, of Denver, has purchased the Farwell water power at the Devils Gate

from W. E. Renshaw and is constructing a dam for storage purposes. He intends erecting a large concentrating mill for the treatment of lead-zinc ore. An expert from Rochester, N. Y., reported favorably on the Denver group on Payne's peak, East Argentine district, last week. The transfer deeds for the property are now being prepared. There are 37 mining claims in the group. The main adit is in 60 ft. and has already cut two of the veins. George W. Hubbard and partners are the vendors.—The St. Paul Mining & Tunnel Co. now has its St. Paul adit in nearly 1,000 ft. The breast is in a lode, which is believed to be an extension of the Equator vein of the Colorado Central mine. The next vein expected to be cut by the adit is the extension of the Colorado Central itself. About 1,000 ft. east of the adit these veins are producing largely and have a past production of \$10,000,000 to their credit.—Work has been resumed on the Bernhardt group, which lies east of the St. Paul, between it and the Colorado Central, and through which ground the same veins run.—Cogshall & Co., owners of the group, are driving one of the lodes which shows a large body of mineralized quartz.—The Waukegan Mining Co., operating claims on the main range near Loveland Pass, is putting in supplies for the winter and preparing to send in a large amount of ore now on the dump before snow blocks the trail. There is a vein of lead ore being opened up in the Josephine on Kelso mountain. A bridge 70 ft. long has lately been built across the creek to facilitate the transport of the ore.

Georgetown, September 28.

HINSDALE COUNTY.

(Special Correspondence).—R. J. Kilvert has a lease on the old Golden Fleece mine, but he is doing very little. It is his opinion that if the company owning the Fleece would expend a few thousand dollars on development, which a lessee is not in a position to do, the mine could be made to pay handsomely.—F. D. Goody has a lease on the Fleece dump and is treating the ore by cyanide. The precious metals occur in petzite, associated with pyrite and chalcocopyrite. The plant is a small one, consisting of six 100-gal. tanks. The ore is given a double wash of lime as a preliminary treatment. Each vat is charged with a strong solution of cyanide first; after ten days it is washed with water and then discharged. The extraction is fair, considering the bad elements in the ore, which carries arsenic, antimony, and free sulphuric acid. The material treated is coarse, and this necessitates long treatment; if it were crushed fine and agitated, the process would require hours where it now consumes days. On account of the vats being in the open it is necessary to close down during the winter months.—The Pittsburg Metals Mining & Milling Co. is installing a hoisting plant near the top of the range above Henson creek.

The Hannah Mining & Milling Co., above Capitol City on Henson creek, completed its mill in July. It is now installing 4,200 ft. of 20 and 24-in. steel pipe, having a 400-ft. head of water for generating power. With the amount of water and present equipment it expects to generate 300 h.p., to supply its own property first with power and then to sell the surplus to neighboring properties. Temple electric drills and air drills are to be used for stoping. The mill was designed by F. W. Sherman, superintendent of the Daly-West mill, at Park City, Utah, and contains many of his original ideas. As designed, it has a capacity of 100 tons per day. G. H. Martin is president and manager of the company. W. R. Davey has charge of the installation of the power-plant.—G. D. Bardwell, operating the Yellow Medicine on the North Fork of Henson creek, has a contract with the Hannah Mining & Milling Co. to furnish it with not less than 700 tons nor more than 1,000 tons of ore per month while doing certain development work in the Oro. Bardwell is also shipping two cars per week of crude ore. The ore is valuable for copper and zinc. He is operating at present on the fourth level, which is 1,200 ft. long. He claims to have 20,000 tons of ore in sight in the mine.—Gustav Wilke, manager of the Planet Milling & Refining Co., is re-timbering the old raise from the cross-cut to the surface on the Red Rover property. The mine is being worked by lessees at present.

Lake City, Colo., September 25.

OURAY COUNTY.

Work on the new mill of the Camp Bird is being rushed as rapidly as possible. The tramway is again in commission after having been partially destroyed by fire and snow-slides last spring. In order to ward against further damage by slides the Camp Bird Co. has erected a number of heavy cribs or fences a short distance apart near the top of the mountain where the slides start to run. In this manner manager W. J. Cox hopes to prevent the snow starting to slide as it is believed the fences will hold it. Last night a portion of the bunk and boarding house was destroyed by fire at the Revenue mine and mill. The fire burned off the roof, but superintendent E. A. Krisher and men saved the bake shop and dining room. About 160 men are employed at present on the Revenue.—The Atlas Mining & Milling Co., of which Fred Carroll is general manager and J. P. Sidwell of Chicago, president, expects to have the 10-stamp mill running in the next 30 days. They are waiting on material for the aerial tramway. Some is on the road and expected to arrive at any time. As soon as received work will be rushed on the tramway. The mine of this company is located in Sidney basin about one mile above the Revenue mill in Sneffels district. The mill contains 10 stamps but the company expects to increase to 30 stamps. A large amount of development work has been done on the property at the surface but it was decided to be a more feasible scheme to drive a cross-cut tunnel to tap the veins at a greater depth and upraise to the surface which is now being done. The tunnel is in something like 2,100 ft. and has crossed two veins. The first vein encountered is known as the Crown Point on which over 500 ft. of development work has been done. The ore from this vein carries considerable free gold. The other vein tapped by the tunnel shows good values in lead, silver, gold, and some copper. Work in the mine is being done by the Temple electric air-drill, which manager Carroll as well as the men operating the drill says is doing excellent work. Power is furnished by the Telluride Power Co., wires being brought over from the Telluride side.

Ouray, Colo., September 22.

SAN JUAN COUNTY.

(Special Correspondence).—Richard Whinnerah has a contract for driving the Bagley tunnel of the Frisco Mining Co. a distance of 5,000 ft. He now has 1,750 ft. of tunnel completed. It is expected this tunnel will tap the Sewell and Red Cloud veins. Sixteen hundred feet from the portal one vein was encountered which carries some values. Preparations are being made to equip with electric power which will be furnished by the Animas Power Co. at Rockwood. The accident to the power plant at Rockwood was rather serious but they immediately made arrangements with the Silver Lake Co. to use the power from the Silver Lake plant above Silverton and within 48 hours were supplying their customers with the necessary power. In no other part of Colorado is electric power used as universally as it is through the San Juan country.

Animas Forks, Colo., September 22.

SAN MIGUEL COUNTY.

(Special Correspondence).—It is not uncommon throughout this part of Colorado to see a sign 'Men Wanted' hanging on the office-door; in fact, there is a scarcity of all classes of help.—The Tomboy has about completed installing new mortars in its mill.—The ore now being brought down from the Smuggler mines is the best in years and the outlook for both the lessee and the company is most encouraging. The extraction obtained in the new mill of the Smuggler Union Co. since the institution of the Pierce amalgamators is much better than before.—The Black Bear in Bridal basin is undergoing extensive development, and a new mill is being erected on the property. L. Kaanta is president of the company.

The most important work being done on the Liberty Bell mine is a raise to connect with the Stillwell cross-cut. When this connection is completed it will enable the company to work the ground opened up by the cross-cut, which is 1,000 ft. on the vein. This company has been having some trouble of late with ore thieves. One party confessed

to petty larceny, as the amount of ore found on him was less than \$20; another one is out on bail. Portions of the mine contain some very high-grade gold ore. C. A. Chase is superintendent; E. W. Nutter, assistant superintendent, and W. E. Tracy, mill superintendent.

Telluride, September 19.

(Special Correspondence).—Tyndel Rynard, general manager of the Vanadium Alloys Co., is increasing the capacity of his plant for handling the vanadium ore from his district. The plant now has a daily capacity of 25 tons. This is said to be the first plant of its kind in the country for handling this class of ore. The product from the mill is shipped to Niagara Falls.

Newmire, September 20.

IDAHO.

ELMORE COUNTY.

The Bagdad-Chase Mining Co., of Rochester, N. Y., has bought the Pettit mine at Atlanta for \$150,000, and it is said that a \$50,000 plant will be installed the coming winter. The mine is a lead-silver-zinc proposition.

IDAHO COUNTY.

Work has been resumed at the Fairview mine, at Roosevelt, by M. E. Eby. — Superintendent Trewick expects to have the Sunnyside cyanide plant finished before winter.

NEZ PERCE COUNTY.

George S. Bailey, manager of the Ozark and Wild Rose gold mines at Pierce City, reports that on the Wild Rose they have a 10-ton roller mill and a 20-ton cyanide plant, and are negotiating for stamp-mills for both mines and also a cyanide plant to treat all the tailing. There are 2,500 ft. of drifts on the Ozark, and from a large station on the 110-ft. level they have commenced to sink a shaft 500 ft. in depth. The Wild Rose is two miles east of the Ozark. This is the ground originally owned by Dunn brothers of Wallace, Idaho. They extracted from \$50,000 to \$60,000 with a two-stamp mill, and the greatest depth attained was 40 ft. It is the intention of the Ozark Co. to drive a cross-cut tunnel 1,280 ft. in length to cut the present workings on the Ozark at a depth of 587 ft. At the 110-ft. level there is a 31-ft. lead, carrying a rich pay-streak on the foot-wall four feet wide, which is now being mined and milled. They are preparing the ground for square setting, so as to mine and reduce lower grade ore as soon as larger mills are erected. As soon as its 1,280-ft. tunnel is completed, the company will move all plants and camps to that point.—M. H. Hare recently purchased the Gaffney placers at Pierce City and is operating a dredging machine successfully, handling from 1,200 to 1,500 yards daily.—The Santiago and Fleetwood claims have been bought by Spokane people. They have a large force at work and have started up their two-stamp prospecting mill.

SHOSHONE COUNTY.

John H. Nordquist proposes starting a 1,000-ft. cross-cut to test, at a depth of 550 ft., the lode of the newly incorporated Lucky Calumet Co., of Wallace. It is thought that the nine claims of the company cover the extension of the Snowstorm ledge.—In consequence of a bond taken on the Ambergris mine by Mayor Rossi, A. Page, and A. Devlin of Wardner, the 90-ft. shaft is to be sunk 200 ft. deeper and 200 ft. of drifts are to be run.—A new hoist and pump are to be put in. At the Page Mining Co.'s property, west of Government gulch below Wardner, the three-compartment shaft is down 54 ft. and a contract has been let to put it down to the 250-ft. level. A cross-cut is to be started. Bunk and boarding houses have been completed. A boiler, hoist, and pump, are now on the ground. W. Clayton Miller, general manager of the Federal Co., is consulting mining engineer for the Page Co.—The Hunter Creek Co., which owns two claims adjoining the Hunter and Little Chief mines, at Mullan, has resumed work under the direction of H. F. Samuels. A 200-ft. extension of the present adit on the Belmont is being driven; it is now in 350 ft.—The Monitor Co. is shipping ore. Everything is being put into shape to enable continuous operation this winter. Timbers sufficient to deepen the shaft 200 ft. are being framed and a contract has been let for 300 cords of wood and a large quantity of

lagging and other mine timbers. The main shaft is down 340 ft. and the drift on the 200-ft. level, now 130 ft. from the shaft, continues to show high-grade ore.—In the Stevens Peak copper belt, the Champion mine is opened by an adit in 625 ft., with a depth at the face of 225 ft.—It will be continued to get under a blowout of ore 150 ft. ahead of the present workings. Adam O'Donnell, the manager, has shipped 800 ft. of air-pipe, a fan, and sufficient supplies of all kinds to permit of work being continued all winter.

A concentrator is to be put in at the Tamarack & Chesapeake mine near Wallace, during the spring of 1907. E. R. Day is manager. Shipping is to be started as soon as the mine has been re-timbered.

Judge Beatty, sitting in the Federal Court at Boise, has declined to entertain a motion for an injunction to enjoin the Federal Mining Co. from dumping its tailing, announcing that such an order would tie up the mines and throw hundreds of men out of work. This leaves the question of damages the sole issue in the proceedings instituted by Brown and others against the Federal company.

Peter Bernier, president and manager of the Black Bear Fraction Co., near Gem, has purchased a five-drill compressor and one 75-h.p. motor, which will be installed and in working order about November 1. A second adit has been started 115 ft. higher than the railroad track; it will be 2,300 ft. long when completed. Nearly 300 ft. have been driven by hand, and the remaining 2,000 will be run by the compressor. Arrangements are being completed with the Washington Water Power Co. to furnish power for the motors.

WASHINGTON COUNTY.

The National Copper Mines Co. has 18 claims near Cuprum. Development work has been going on since May, 1905, by W. Trevor. The company is waiting for cheaper transportation before shipping.

The Goodenough Mining Co. is putting a five-stamp experimental mill at Marshall lake, near Council.

MONTANA.

FERGUS COUNTY.

Title to the \$3,000,000 Kendall mine near Kendall, is disputed in a suit filed in the District Court at Helena by E. H. Bragg and I. I. Nelson of Cincinnati, O., against John A. Finch, A. B. Campbell of Spokane, and Henry Wick and the Kendall Gold Mining Co. The plaintiffs claim to have an option on an undivided half-interest, dating 1901, but that in the last year an interest has been sold to Henry Wicks without the knowledge of the complainants, who now ask for an injunction staying further operations at the mine; also for the delivery of the option.

NEVADA.

LINCOLN COUNTY.

(Special Correspondence).—Free gold has been struck at Newberry mountain, 18 miles southeast of Searchlight, by John Thurman and Charles Hamill. The new district is five miles from the Colorado river.—The Black Hawk, Venus, and Mountain El Dorado companies in El Dorado canyon have been consolidated into the Black Hawk Con. Mining Co.—Thomas Gahagan has bonded the Belle group, adjoining the Venus on the south, for \$25,000. The group consists of four full claims, with five parallel veins traversing the entire length of the property.—E. J. Roberts, as superintendent, has resumed development work on the El Dorado Nevada, and with the installation of machinery, sinking will be resumed. Another shaft will be sunk on the Captain claim to water-level.—The El Dorado Sphinx Mining Co. is running an adit on the Silver Sphinx claim to reach the vein on the Combination Mines Co., that extends through its property. A. J. Peak, who is superintendent, has men building a new wagon-road from Nob hill, two miles distant.—The Cyrus Noble mill has resumed and enough water has been secured to run three shifts. The mine is being developed to the 500-ft. level, and enough ore has been blocked out from the 300 to the 400-ft. level to run the mill, three shifts, for six months.—The Duplex Extension Co. has let a contract to sink a 5½ by 11 ft. double-compartment shaft to water-level. The shaft will be sunk on the Eucher claim, with cross-cuts at each level

Superintendent Essenderft has ordered machinery. — Ore has been found on the Wyoming Searchlight Co.'s estate, west of Searchlight.—The cyanide plant of the Searchlight Mining & Milling Co. will be in running order in three weeks.—The American Mines & Securities Co., of Denver, is operating the Fortuna group in El Dorado canyon, formerly the property of Jacob Stoner. A. McKnight is in charge of the development and has 24 miners at work. The company has a bond on the adjoining group of five claims belonging to the American Development Co. — C. E. L. Gresh has purchased a concentrating plant for the Black Hawk Con. Mining Co. The company has a 10-stamp mill on the ground at the present time about to be erected, and will also have concentrators to treat the sulphide ore.

Searchlight, September 28.

(Special Correspondence).—The pleasant cool weather has caused a noticeable increase in the number of new arrivals here. The Utah & Nevada Stage Co. has had to put on extra stages and can now handle 70 passengers per day both ways, and is fully capable of handling the traffic until the railroad reaches here. The road is being rapidly built into Searchlight, the grade being completed within ten miles of the town. The Manville & Searchlight stage line, connecting with the Santa Fe railroad, is also equipped to handle a large number of passengers. It is a fortunate thing for the Searchlight district that—unlike many of the northern camps—the hotel and restaurant accommodations are ample.—Sinking has been resumed in the Cyrus Noble Extension shaft, the timbering having been completed. This property is located between the Cyrus Noble and the Parallel, and it seems likely that the mine with depth will equal its neighbor, similar ore having already been encountered.—In the Quartette, a cross-cut is being driven into the foot-wall of the Drake shaft at water-level, 250 ft. The ground was prospected prior to resuming sinking, there being some delay in securing a desirable pump. Drifts are being pushed on the 800-ft. level and, though no cross-cutting is being done, the indications are that the orebody will equal that of the level above.—The Boulder Mining Co. has let a contract for 100 ft. of development. The main shaft is down 200 ft. and will be sunk 40 ft. farther.—The Sunrise group of 12 claims, three miles east of the Quartette, has been bonded to G. W. Huntington and associates. The claims were the first located in this new part of the district and the indications are exceptionally good.—The Searchlight-Wyoming Co. has installed a 25-h.p. hoist and has resumed sinking from the 200-ft. level. The showing is very promising.—Operations will be commenced on the Gold Dyke Mining Co.'s property within the next 30 days. They will sink to the 500-ft. level from the present shaft (103 ft. deep) which has a 60-ft. cross-cut exposing 20 ft. of high-grade ore. The Gold Dyke promises to be one of the large mines of the Searchlight district. This property immediately adjoins the Pompeii on the west and the Blossom on the north.

Searchlight, September 15.

LYON COUNTY.

Twenty-three locators have staked ground in the new camp of Arrowhead, near Yerington. The Kockel brothers have nine veins on their ground. Some of them show ore going from \$60 to \$70 per ton. John McEwin has a good prospect and Charles McNeil has a claim from which fine pannings are obtained. The Kockel brothers have over 10 tons of ore on the dump and are arranging to make a mill test.

WHITE PINE COUNTY.

The completion of the Nevada Northern railway between Ely and Coburn, on the main line of the Union Pacific, was marked by a big celebration at Ely on September 29. This road will open up the wonderful copper deposits of this region.

OREGON.

BAKER COUNTY.

Oscar Eckstein and Wilfred Fralic have devised a method of treating black sand and intend erecting a reduction plant on the Snake river, near Huntington.

The Golconda mine, near Bourne, has been closed temporarily.

MALHEUR COUNTY.

For a number of years natural gas, in limited quantity, has been known to exist at Ontario. A well drilled at the Boyer place, at the south end of town, furnishes sufficient gas for lighting, cooking, and heating. David Wilson, of Spokane, owner of the townsite of Ontario, together with J. R. Blackesly, H. C. Boyer, W. E. Lees, and Ward Canfield, have organized the Ontario Co-operative Gas & Oil Co. It is their intention to secure 25,000 acres, under 25 years lease, surrounding Ontario. Ontario is on the Oregon Short Line railway, in eastern Oregon, 40 miles east of Huntington and 60 miles west of Boise City, at the junction of the Malheur river with the Snake river.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Dominion Copper Co., of Boundary Falls, B. C., has bonded from the Reservation Mining & Milling Co. the Lone Star and Washington claims, near Danville, and several other claims are being negotiated for by the former company. Ten men are sinking a shaft and raising to it from an adit on the Lone Star.—The annual assessment work on the Faithful-Surprise claims was recently finished. The Surprise tunnel, during the work, ran into a fine body of rich ore.—One shift of men is employed in making a connection between the No. 3 adit and the No. 2 adit workings in the Belcher mine. Owing to the blower having been removed from the No. 3 adit, the air is bad.—The Oversight Mining & Milling Co. is prepared to make regular shipments of ore from the Oversight claim and is making contracts for the haulage to the Belcher Mountain railway as soon as the laying of the track is finished.—The installation of the compressor plant at the Minnehaha mine has been completed, and the new tunnel has been started.

Danville, October 1.

Ira J. Hallensbe, of the Indiana Consolidated Smelting Co., and the Silver Creek Mining & Milling Co., at Keller, on the south half of the Colville Indian Reservation, states that this smelter is of 150 tons daily capacity, and will reduce copper and lead ores.

BRITISH COLUMBIA.

KOOTENAY DISTRICT.

It is reported that the 1,400-ft. level of the St. Eugene, at Moyie, East Kootenay, is looking well, as new shoots of ore have been uncovered there, and they are known to be as wide as the drift. Stopping will determine how much wider they are. Besides this an important shoot has been found on the 1,900-ft. level.

MEXICO.

SONORA.

After having cleared the mine of water, the Greene Gold Co. has decided to abandon the present system of operating and install dredges on its placer properties at La Brisca. When it opened up the placer beds at La Brisca the company installed a system of aerial tramways to convey the dirt to the sluices after it was removed from the workings by the machinery especially constructed for that purpose. The property had just been placed on a producing basis when the rainy season set in last year. The rainfall was so heavy and continuous that the pumping plant, which has a capacity of 3,000,000 gal., was unable to handle the water which flowed into the workings and it was necessary to suspend operations.

MEXICO.

The Mexican Light & Power Co., of Montreal, Canada, at its annual meeting, announced the intention to expand its operations. By September 15 it will have, ready for use, six turbines of 8,200 h.p. each, operating six 5,000 k.w. generators. The transmission lines run to Mexico City and to El Oro; it is intended to extend the wires to all the important towns in the Federal District. The company has secured comprehensive water rights on the Necaxa and Tenango rivers. The earnings for the first six months of 1906 amounted to \$1,754,833 pesos, as against 752,330 pesos for operating expenses. It is estimated that the net earnings next year will be \$157,000 gold.

Personal.

A. B. CALL is at Grant's Pass, Oregon.

T. BRUCE MARRIOTT is in the Argentine.

BEN B. LAWRENCE has been to Salt Lake.

FORBES RICKARD is at Searchlight, Nevada.

GEORNE W. MAYNARD is at Tucson, Arizona.

ARTHUR WINSLOW has returned to Boston from Europe.

W. J. ELMENDORF, of Spokane, is examining mines in Alaska.

ARTHUR L. WALKER is expected at San Francisco on October 12.

JOHN W. Z. Earle has returned from Mexico to Patagonia, Arizona.

JAMES F. KEMP sailed for New York from Vera Cruz on the *Seguranca*.

R. L. LLOYD is now with the Teziutlan Copper Co., at Teziutlan, Mexico.

HENRY F. MACKAY is superintendent of the Llanos de Oro mine, in Sonora.

EDGAR A. COLLINS, who was married recently, visited San Francisco last week.

E. B. LICHTENBERG has left London to go to the Gold Coast Colony, West Africa.

J. W. MERCER has returned from a summer tour in Europe and is now in New York.

FERDINAND SUSTERSIC, manager for the Amparo Mining Co., was at Mexico City recently.

J. PARKE CHANNING and C. L. CONANT, of New York, have been at Butte during the week.

NOEL GRIFFIN has gone to Egypt on his appointment as manager of the Nile Valley Company.

BANDMANN & ADAMS have moved to permanent offices in the Monadnock Bdg., San Francisco.

W. A. HOEING has been appointed manager for the Compania Minera de Tetela, in Puebla, Mexico.

FRED. G. FARISH has just returned from a three months' trip into Mexico and is now at Helena, Montana.

F. L. BOSQUI is designing mills for the Montana-Tonopah Co. and the Tonopah Exploration Co., of Nevada.

HARRY H. WEBB is in San Francisco, on a visit from South Africa. He will proceed to Mexico shortly.

THEODORE J. HOOVER, who is in London, is to be manager for the company owning the Catermole process.

THOS. M. HUGHES has resigned as superintendent of the Creston mines, in the Hostotipaquillo district, Mexico.

T. W. E. DAVID, professor of geology in Sydney University, returned to Australia on the *Sonoma*, sailing on October 4.

HARRY INGERSOLL has been appointed superintendent of the San Francisco mine, in the Taviche district of Oaxaca, Mexico.

FRANCIS A. THOMSON has been appointed professor of mining and metallurgy in the Washington State College, at Pullman.

W. H. STAVER, assistant manager for the South American Development Co., is examining properties at Inde, Durango, Mexico.

Obituary.

P. J. GROSS died at Placerville, California, on September 27, from the effects of paralysis. He had been operating El Dorado mines since 1865.

PHILIP FERDINAND KOBBE, director and assistant secretary of the Westinghouse Electric & Mfg. Co., died at his summer home at Stockbridge, Mass., on September 21, aged 64 years. Mr. Kobbe was one of the pioneers in the electrical business, his efforts always having been devoted to the financial end. In 1883 he was elected treasurer of the United States Electric Lighting Co., which position he held until 1890, when the United States Electric Lighting Co. was absorbed by the Westinghouse Electric & Mfg. Co., at which

time Mr. Kobbe was made treasurer of the latter company. In 1896 Mr. Kobbe was made vice-president in addition to his duties as treasurer, and in 1902 he became a director of the company. It was in the year 1900, when Mr. Kobbe was on his way to Europe to undertake important work in connection with Mr. Westinghouse's foreign interests, that he was stricken by an attack of paralysis, from which it is believed he never fully recovered. Mr. Kobbe was born in New York, October 24, 1842, and received his education in Germany. He was a man of broad culture and of a charming personality that endeared him to all of his associates, so that they were always glad to consider him their friend. He served in the Civil War as a member of the Seventh Regiment. Surviving him are a widow, three daughters, and two sons. Two brothers, Gen. William A. Kobbe, U. S. A., and Gustave Kobbe, author and journalist, of New York City, also survive.

In the passing away of Mr. Kobbe the interests with which he was so long associated lose one who throughout his career has been the embodiment of industry and honor.

Dividends.

On October 4, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 109 of \$180,000. This makes the total paid since January 1, 1906, \$1,800,000 and to date, \$7,326,000.

Esperanza, Ltd., of El Oro, Mexico, and London, has declared a regular quarterly dividend of 12½ cents and an additional dividend of \$2.50, payable on October 22.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE mining district making the largest output of platinum is South Verchotursky in the Ural mountains, separating Europe from Asia. In 1905 the yield was 124,375 oz., as compared with 124,563 oz. the year before.

THE size and shape of a shovel make a marked difference in the efficiency of a workman. A small round-pointed shovel must be used in tough soils, but only large, square-pointed scoops should be used in handling earth off boards or in shoveling sand, unless it be to cast it some distance.

IN California, preliminary location work is not required. The locator has one year from the first day of January next succeeding the date of his location, to perform the \$100 worth of work required by the Federal law. No work need be done during the period preceding this, in this State.

THE ordinary gait of average buggy horses is 9 miles per hour, 14 miles being a maximum. Seven miles an hour is a fair pace for a horse when ridden. A horse will walk from 3 to 4 miles per hour. A freight camel goes 2 to 2½ miles and a trotting camel 7 to 7½ miles per hour, accomplishing 100 miles without rest.

No less than 77 vessels of a length of 500 ft. or more have been ordered since 1904 for the freight trade on the Great Lakes. The average cargo is 9,000 tons, and some of these boats carry 12,000 tons of iron ore apiece. They possess nearly three times the capacity of the vessels engaged in this trade ten years ago.

WHERE inside amalgamation cannot be successfully carried on inside a Huntington, Bryan, Kinkead, Chile, or other rotary mill, outside plates properly disposed will be found efficient. There are many instances where amalgamation inside a stamp battery is not satisfactory, and in other cases amalgamation is accomplished by preference on outside plates.

THE amount of money paid respectively, for labor and for supplies, in the operation of mines in the United States, is in the ratio of 62 to 38. At the Esperanza mine in Mexico it is 58 to 42. The tendency during recent years is to lower the percentage cost of labor in mining operations by the substitution of machinery and automatic devices wherever possible.

THE wolframite occurring in the quartzite overlying the gold-bearing conglomerate at Lead City, South Dakota, was first recognized by an amateur mineral collector, who was a teacher in the high school at Lead. He properly determined the black granular ore to be wolframite. Miners had for 20 years thrown it away thinking it only an ordinary iron ore.

WHERE gold can still be recovered from the lower part of the lowest plate of a series of apron plates in a stamp-mill it is usually good business to put in additional plate surface. If there is no room for this addition inside the mill building then the plates may be placed in a separate building, where it may be convenient, but preferably wherever the pulp will flow to it by gravity.

PURE WATER at a high temperature is a solvent for many mineral substances. The silicates composing soft

glass are rapidly attacked by water at a temperature exceeding 185° C., and at 180° zeolites can be readily dissolved in pure water, the mineral crystallizing out on cooling. At higher temperatures many natural silicates are soluble, and this fact is, without doubt, of importance in the formation of mineral veins.

CONCRETE should be mixed as near the point of use as possible, and a long trip in a wheelbarrow is to be avoided. When it must be handled by wheelbarrow, it is best to dump the concrete on a small platform and shovel it over, before putting it in place care should be taken that all parts are equally wet; otherwise some portions of the work may dry before others, and thus cause cracks.

THE largest shipment of specie ever brought to this country arrived on the Cunard steamer *Carmania*, reaching New York on September 19. She brought \$10,328,500 in gold coin and bars. The precious metal on the Cunarder was in 275 boxes, each box containing from 250 to 350 lb. of gold. During the voyage the gold was placed in the specie room on the main deck, guarded night and day by three armed men, each trio being relieved every six hours.

IN some mills where the ore is free-milling, there is still found 20 to 25% of the gold in the tailing after passing the plates. In some instances the saving may be increased by addition of more plate surface. In others if the plates already in the mill are kept in the best condition no additional plates will be necessary. A careful millman will not allow sand to bank up on his plates, nor permit bronze-colored spots to remain untouched long. Neither the space covered with sand nor the discolored spot will catch a particle of gold.

IN ORDER to prevent a forfeiture for failure to perform the assessment work required by law, the claimant must resume work in good faith and prosecute the same continuously without unreasonable interruption until the full amount of labor is performed; that is, one year's delinquency must be made up. Under the circumstances stated in the inquiry, after the performance of \$100 worth of work in the manner suggested therein, the claim would not be subject to re-location until the first day of January following the completion of the work.

IF A buys a mining claim from B in June, 1902, the last payment becoming due six months later; and if A has the claim patented in B's name before the last payment is due and the receiver's receipt is issued by the U. S. Land Office in favor of B; and if A then makes his last payment and gets a warranty deed from B, both deed and receipt being recorded; and if one year later the Government patent is issued in B's name, then, although the patent is dated later than the deed, A need not secure an additional quit claim deed from B to make title good in A's name.

THE date of the discovery of iron has long been a matter of controversy; and it is generally believed that the iron first used by man was of meteoric origin. In support of this view Otto Vogel has given quotations from the earliest Finnish poem; and Sir Henry Bessemer in 1895 adduced evidence to show that the tools used in the construction of the Pyramids must have been made of a meteoric nickel-iron alloy. The theory is, however, open to considerable doubt, in view of the difficulty of working meteoric iron. Indeed, many authorities have denied that meteoric iron is malleable. The hypothesis is, nevertheless, an attractive one. Blocks of meteoric iron, though not very numerous, have been found in all parts of the world.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Who Is a Mining Engineer?

The Editor:

Sir—The plea of 'Viator' in your No. 2,402 for a legal definition of 'Who is a mining engineer?' is answered by the common estimate of the values of the titles attorney-at-law or lawyer, dentist, doctor, plumber, barber, etc. All these and many more are legally conferred by State boards only, in one or many States. But they have no great weight with public opinion. He is entirely justified in his strictures on the mining engineer graduated from journalism. This is the most dangerous quack of all; the others can usually be detected by their omissions and inaccurate use of words.

In No. 2,407 'Engineer' gives a fair definition of a mining engineer, but he—like others in previous discussions—appears to give too little prominence to definiteness of opinion in a report, and to the character of the man as evidenced either internally in the report or otherwise known. A mining engineer must not only know what he enumerates, but he must be—and show himself to be—entirely unbiased. The facts seen and vouched for must be clearly distinguished from any opinion, and the final opinion must be as definite and exact as the circumstances will allow; the answer will nearly always be possible in dollars and cents.

To attempt to define the status of a mining engineer in this State will only be to put us to the level of plumbers, barbers, and veterinarians; to do so by voluntary associations like the American Institute of Mining Engineers would be ineffective and extra-legal. Those of us twenty years out of the college that had a legal right to confer the title, know what a very small percentage of our present attainment is that rudimentary part which was acquired there; we ought readily to acknowledge the right of the man who did not have that short cut but has nevertheless reached the same end by harder and more laborious path and has earned the use of the title of 'mining engineer.'

J. C. HEWETT.

Colorado Springs, September 13.

Who Is a Mining Engineer?

The Editor:

Sir—This discussion, like many others, hinges very largely on a verbal definition. Words are like tools. We may take a word and put it to many uses for which it was not originally designed, just as we may use a tool for many purposes for which it was not originally designed. We may use a pitchfork to handle gravel and a shovel to handle hay, but it is always much better to use both words and tools for the purposes for which they were designed and the only excuse there is—that is at all a valid excuse—for using a word or a tool for other purposes than that for which it was designed is that there is no other word or tool at hand which will better serve the purpose.

Now I believe the recognized authority now-a-days on the meaning of words, which is another way of saying the use for which they were designed, is the Century dictionary. The latter work defines an engineer as "one skilled in the principles and practice of any department of engineering." Mining engineering is defined as "that branch which relates to all the operations involved in selecting, testing, opening, and working mines." Now let us notice these definitions carefully; an engineer is

one skilled in the 'principles and practice.' Not principles alone, nor practice alone. That throws out at once the man who has had lots of practical experience and no technical training and the man who has had lots of technical training and no experience. The newly graduated college student is not a mining engineer, neither is the old mining man who has made money out of mines, but never studied the 'principles.'

Let us now consider the definition of mining engineering. "That branch which relates to *all* the operations involved in selecting, testing, opening, and working mines." Here again we have the same idea reiterated. "*All* the operations"—not part of them. Not the part which pertains to technical training alone, nor the part that pertains to practice alone, but "*all* the operations." Not the part that pertains to milling alone, or smelting alone, or surveying alone, or mining alone, but "*all* the operations involved in *selecting, testing, opening, and working* mines." Truly the mining engineer must be an all-round man. The man who has specialized on any branch of our many-sided profession is not entitled to the title of mining engineer. He may be a chemical engineer, or a surveying engineer, or a milling engineer, or an excavating engineer, or a smelting engineer, but he is not a mining engineer.

I have heard it argued that the man who prostitutes his profession by taking part in wild-cat schemes was not entitled to be called a mining engineer. If my premises are accepted, the only excuse there is for using a word for some other purpose than that for which it was intended is that there is no better word at hand. It is true that the term 'mining engineer' might be broadened to carry a moral significance, but what is the need of it? We can speak of honest mining engineers and dishonest mining engineers. So long as a man is "skilled in the *principles and practice of all* the operations" of mining, he is to my mind a mining engineer; otherwise he is not a mining engineer.

Denver, September 18.

Copper in Cyanide Solutions.

The Editor:

Sir—As to copper in cyanide solutions, finding facts here at variance with those published in your issue of September 1, I thought an account of our practice here would be of interest, as well as our manner of making pure bullion from a zinc-box product high in copper.

The gold-bearing ore consists of hematite and clay in about equal proportions and 0.75% copper. On account of the clay, roasting is required to effect dehydration. Without such dehydration the treatment of slime, which amounts to over 50%, would be impossible, either by filter-pressing or decantation. The latter is the method we employ, using shallow vats 19 in. high, which settle completely in four hours, including the decantation of the clear solution. The loss in cyanide is about four pounds per ton, with a solution containing 1½ lb. cyanide.

The zinc-boxes, of eight compartments each, show pure copper in the last two compartments, and gradually turn black toward the head. The copper is not loose and spongy, but adheres firmly, and to all appearances looks like pure copper shaving. I am inclined to believe that, in this instance at least, copper helps in the precipitation of gold and silver because a copper hue on the zinc has always been a proof that the sump assays only a trace in gold. These coppered shavings when treated with sulphuric acid, and then cupelled, yield gold 1,000 fine; so that the sump must be free from silver.

We have found it necessary on but two occasions during the past two years to dress the zinc in the boxes and then the last compartments were not coated with appre-

ciable amounts of copper. We simply clean up the first and part of the second compartments every month, unless previously gold slime has so accumulated that it retards the proper flow of solution.

The short zinc is not removed. We find in this fact a contradiction to many authors who claim short zinc to be inert. The fact that we can return short zinc with no accumulation of such product, is a proof of its precipitating qualities. Only what can be washed through a 20-mesh screen is treated with acid and—this before acid treatment—is separated by stirring in water and decanting the suspended slime until only a coarse granular mass is left. The latter is treated with sulphuric acid and the former with hydrochloric acid. The slime contains a large percentage of calcium carbonate, which forbids the use of sulphuric acid on account of the regulus that would be formed in melting and on account of adulteration of precipitate with sulphate of lime.

Ten parts of the coarse or 12 parts of the slime after acid treatment are melted in a graphite crucible with about eight parts of a mixture of 26 litharge, 20 borax glass, and one nitre. The melting must be quickly performed to prevent formation of too much lead from the action of the graphite in the crucible, and unless considerable experience is obtained as to the proper time and heat, a flux consisting of equal parts of bicarbonate of soda and borax glass would be safer. The use of litharge, on account of its rapid shrinking before complete melting, allows of several fillings before fusion. The flux and charge are mixed after wetting sufficient to prevent dusting.

The smaller bars resulting from different melts are now ready for refining as follows: Place inside of No. 35 graphite crucible, a Battersea P crucible so that the bottoms of each touch. To accomplish this, the graphite crucible must be slightly clipped inside for about an inch from the top. Melt the bars in the clay crucible and then add, from time to time, a little nitre until the metal is covered with slag, which should then be skimmed by means of a small crucible (10 grams) held with tongs. Repeat the adding of nitre and skimming until the skimmings show but little lead and the bullion looks bright. On an average, the bars which before refining are 700 to 800 fine, yield by above treatment bars of over 900 fine.

In case the soda flux is used, about five per cent metallic lead should be melted with the bar, as without lead the copper is difficult to remove. The refining takes about an hour after melting. If all the melts are made, using a clay crucible direct, bullion of 985 fine can be produced in the original melt, using either litharge or soda flux. However, as I was not able to obtain larger clay crucibles than the Battersea P size and as the heat must travel through two crucibles, clay breaking in direct contact with coke, I found it preferable to refine in one melt.

Zinc-Dust Precipitation.

The Editor:

Sir—After reading your remarks concerning zinc-dust precipitation I have been enquiring among my professional friends and from one of them I have secured information which I feel sure will interest others as much as it did me. This engineer was superintendent of a 100-ton sand and slime-plant. Slime was treated by decantation and sand by percolation, the ore containing both silver and gold, with over 50% of the value in gold.

The precipitation plant consisted of three 15-ton flat-bottomed wooden tanks, a six-inch self-acting compressor, a four-inch triplex belt-driven plunger-pump, and two 2.5-ton filter-presses. One of the latter was a Johnston press with six-inch frames. The leach from sand and slime ran to a sump whence it was pumped to one of the three agitation vats. This pregnant solution was worth about \$2 per ton. The compressor was started and air pumped through a $\frac{3}{4}$ in. line to a grating of half-inch pipes in the bottom of the vat. These branch pipes were

perforated. Two to four pounds of zinc dust were added (an average of 3.5 lb.) and the agitation with air continued about twenty minutes. The charge was then pumped by means of the triplex plunger through the press. One press held about one month's product. In order that the press should fill completely, it was the custom to close the discharge-cocks of the frames in the half nearest the inlet, gradually opening them as the farther frames became filled.

Zinc-Dust Precipitation at the Mercur Mill, Utah. Agitation Tank in the Background and Filter-Presses in Front. Compressed-Air Receiver to the Right.

The plant treating the ore produced a product worth \$20 per lb., while the plant treating old tailing from a former pan-amalgamation mill made a precipitate worth \$8 per pound.

This precipitate was treated with sulphuric acid, roasted in an iron muffle and melted in pots. The zinc dust costs 5.5 to 6 cents per pound at the works. No attempt was made to remove the zinc oxide with ammonia. The quantity of zinc used was governed by the value of the barren solution. Sometimes an increase of zinc made a better precipitation and at other times an increase in the strength of solution used on the ores attained the same result. A twenty-cent tail-solution was considered very high. The precipitation vats were flat-bottomed, and this necessitated an occasional clean-up, which consisted of hard labor with hammer and chisel. This difficulty could be avoided by having conical-bottomed vats. About 225 tons were precipitated in 24 hours.

The presses would stand a pressure of 40 lb., although it was the custom to fill the presses with as low a pressure as possible, pumping the solution at a rate barely sufficient to keep up with the plant.

No naked flame should be allowed around the press while opening, and the cigarette smokers must be kept at a distance. A flame applied to the charge when the press is first opened will explode the hydrogen mixture, separating the frames and scattering mud.

Some years ago I was shown the plant at Mercur and

no secret was made of the method of precipitation, and the same statement applies to the attitude of those in charge at Lead, South Dakota.

MARK R. LAMB.

Goldfield, Nevada, September 4.

In the Desert of Central Australia.

The accompanying illustrations represent the underground workings and the smelter of the Blinman copper mine in South Australia. It is situated 272 miles north of Adelaide and 14 miles east of the transcontinental railroad.

This mine was worked in the sixties and produced 250,000 lb. previous to 1874, when it closed down. It worked at irregular intervals subsequently, until 1903, when it was purchased by the Tasmanian Copper Co., an English corporation which was formed to work the Rosebery mine in Tasmania, which itself has proved too low-grade for profitable working up to this time. The present proprietors have spent a considerable sum of money

Copper Smelting Furnace. Old Pipes From Mine-pumps Used to Support Feed-floor.

in re-opening the mine, and have erected a modern copper furnace, which smelts 150 tons of ore daily. In 1904, 9,055 lb. was produced; in 1905, up to the end of June, 26,900 lb. It has worked continuously and profitably ever since. At present operations are carried on at the sulphide level, the ore sent to the furnace requiring no roasting and averaging about six per cent copper. The deepest shaft is about 450 ft. below the outcrop. The ore occurs as masses and veins in magnesian limestone, and there is a large body of low-grade material. Only the richer portions are smelted; the great bulk of the ore-bearing formation will require concentration.

In the first photograph, the open-cut on the 90-ft. level is shown. The man is about to dump the content of a car into a mill-hole. In the other is shown the copper smelter, open to the air and in the full glare of the sun. It will be noticed that the supports for the feed-floor are pipes taken from an old mine-pump. The furnace smelts 150 tons of ore per day, making 10 tons of matte, averaging 55% copper.

THE reasoning of many is but little more than a decent pretext for the adoption of foregone conclusions.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The rock from Wadsworth, Nev., marked C. W. is Quartz-mica-diorite, in which the quartz is predominant.

The minerals from Juarez, Chihuahua, Mex., are: No. 1, Heavy Spar (baryta); No. 2, Syenite, with flakes of molybdenite on one side; No. 3 is principally Pyrolusite (manganese oxide) and gypsum.

The rocks from Challis, Idaho, marked O. F. R. are: No. 1, metamorphosed clay rock; No. 2, chert, produced

Open-cut of Blinman Mine, South Australia.

by silicification of some rock, perhaps limestone. It is brecciated and includes fragments of the black rock.

The rocks from Salt Lake, Utah, marked L. L. M. & M. Co., are: No. 1, Contact-breccia, in which the quartzose portion contains much pyrite, though pyrite is disseminated throughout the rock; No. 2 is practically all Silica, and is evidently the result of silicification of some rock, possibly rhyolite. It has the appearance of some Nevada gold ores, and both of these rocks should be assayed for gold and silver.

The rocks from Mammoth, Ariz., marked R. E. D., are: No. 1, Quartz-mica-diorite. In this rock copper carbonate is seen in small amount, usually associated with the biotite, which it has apparently replaced to a slight extent. No. 2, is Aplite, but has suffered some alteration; No. 3 is similar to No. 2, but has become infiltrated with copper carbonate. It should be assayed for gold and silver as well; No. 4 is Mica-diorite; No. 5 is also diorite, but has been crushed and the individual mineral constituents much altered. A little copper carbonate is observed in this rock also.

Ore Treatment at the Combination Mine,
Goldfield, Nevada.

Written for the MINING AND SCIENTIFIC PRESS
By FRANCIS L. BOSQUET.

I. METALLURGY.

The Combination mine, situated about one-half mile northeast of the town of Goldfield, consists of ten full claims and three fractions, aggregating 200 acres. The original discovery on Combination ground was the first of any importance made in the now famous camp. The property was acquired from prospectors in 1903 by the representatives of two Eastern exploration companies, who, after a visit to one of the outlying districts, happened to be passing through the present site of Goldfield on the way to Tonopah; and thus, at the very outset of its career as a gold producer, the Combination was

Hauling Ore to the Railway.

blessed by the happiest accident that can befall a mine—it passed into good hands. The property has since occupied a unique place among the mines of southern Nevada. It has been well administered; it has had the benefit of the most approved and practical methods in mining and metallurgy; and its development has not been hampered by stock manipulations. Consequently, though the most interesting property in the district, whether we consider its varied metallurgical problems, or its ratio of output to small mill-capacity and small development, it is the least advertised and the least discussed.

The first shipments from the Combination were made in December, 1903. The gross output of the mine from the commencement of operations to April 1, 1906, is as follows:

		Value	Total Value.
Shipping ore (tons)	1,773	\$438.24	\$776,892.84
Stamp bullion (oz.)	13,584	19.48	264,506.30
Concentrate (tons)	230	352.05	80,972.07
Cyanide precipitate (lb.)	734	45.77	33,594.18
Cyanide bullion (oz.)	4,401	16.44	72,346.51
			\$1,228,411.90

The property was a shipper from the grass-roots. Almost any grade of ore could be segregated by rough

screening and sorting, the practice being to reserve the milling ore (\$25 to \$100) in graded dumps until the completion of a mill. In shipping it was at first necessary to haul the ore to the railroad, a distance of 60 miles. The costs of transportation and smelter treatment were so high as to emphasize the importance of treatment on the ground, and an investigation was at once commenced with a view to installing a reduction plant.

The ore has been described as a highly silicified dacite occurring in zones of fissuring in the decomposed dacite constituting the country rock. In the more shattered portions of the orebody the dacite is almost entirely altered into quartz, with stringers and patches of kaolinized material. During the progress of the preliminary tests, the ore showed certain freakish variations which made it difficult to decide upon a method of treatment. The fineness of the gold, and the almost entire absence of concentratable material in the upper levels indicated dry-

Original Combination Shaft. Man in Bucket.
(Site Now Occupied by Large Open-Cut.)

crushing, and a testing plant for dry-crushing was installed. But even after a long leaching with cyanide solution, it was still found possible to pan an appreciable quantity of gold from the residue. These tests had scarcely begun before the gold in the mine became coarser, and the proportion of sulphides increased. A series of tests by amalgamation, concentration, and cyanidation, gave decidedly promising results, showing an average saving of 45% by the first, 5% by the second, and about 40% by cyaniding the residual sand and slime—a total of about 90%. Later, it developed that certain portions of the oxidized ore carried a disquieting amount of acid—free sulphuric and ferrous sulphate, with here and there enough alum to make the rock astringent to the taste. In some of the tests the ore was so acid as to require 50 lb. of lime per ton as a neutralizer. But this very acid ore was not found to be in sufficient quantity to affect the general treatment seriously; and in subsequent milling tests an average sample of all the accessible oxidized ore was taken, and the acid condition met by using from 10 to 12 lb. lime per ton.

The results obtained in ore-tests made at Goldfield in

the early months of 1904 were confirmed during the summer by mill-runs made at an ore-testing plant in San Francisco. The representative test, which gave the best results, was made as follows:

1. Crushing through 40-mesh wire screen.
2. Plate amalgamation.
3. Concentration on a Frue vanner.

The Beginning of the Combination Mine.

4. Hydraulic separation of slime in cone-classifiers.
5. Leaching sand with cyanide solution.
6. Agitating slime with cyanide solution.

The best conditions for the sand were found to be eight days' leaching with a 0.2% solution; while the slime required four hours with a 0.15% solution. The following is a record of extraction from slime:

	Gold. OZ.
Assay heads	1.20
Assay after 1 hr. agitation.....	0.46
" " 2 " "	0.20
" " 3 " "	0.14
" " 4 " "	0.12
" " 5 " "	0.12
" " 6 " "	0.13
" " 7 " "	0.12
" " 8 " "	0.12

The amalgamation plate and zinc-box were cleaned up and the following results obtained from the whole test:

Indicated extraction by cyanide, 83.4%.

Actual extraction by cyanide, 77.9%.

Indicated total extraction by all processes, 93%.

Actual total extraction by all processes, 91%.

On a small scale, better results were obtained by crushing to 50 mesh, and it was found that by sliming the whole product, a still higher recovery might be made. But the unproved efficiency of American tube-mills at the time the tests were made and the high cost of power and labor at Goldfield, left the advantage in favor of sliming too small to justify the experiment.

The mill was originally designed to treat oxidized ore only, although in places in the oxidized zone there were found small quantities of sulphide ore which resisted mill treatment by ordinary methods. But as there was no

indication of the development of a large amount of sulphide ore at the time construction commenced on the mill, the installation was allowed to proceed. It was while the mill was being built that large shoots of sulphide ore were opened up as the limit of the oxidized zone was reached, and before the end of the year an extensive dump had accumulated with an average content of about 3 oz. gold. This was reserved for special treatment, and samples taken for investigation.

The sulphide in the 'sulphide ore' of the lower levels is a simple iron pyrite, for the most part finely disseminated. The following is an analysis of the ore:

Silica, 70.4%; alumina, 17.0%; sulphur, 4.2%; iron, 8.5%; and copper, trace.

Direct cyanide treatment was tried in all practicable variations, but without good results.

After grinding through 200 mesh and agitating 15 hr. in a 0.25% cyanide solution, the recovery was only 60%, with a 4-lb. cyanide consumption.

Roasting and leaching a 20-mesh product gave an extraction of 91%, with a 7.2-lb. cyanide consumption.

Roasting a 20-mesh product, re-grinding to 200-mesh, and cyaniding by agitation in a 0.25% solution gave 93% extraction.

Pan amalgamation of the roasted ore gave an extraction of 54 per cent.

Oil concentration (Elmore process) of raw ore, with

Goldfield, at Sunset, in 1904.

agitation of tailing in cyanide solution, gave 90% extraction with a consumption of 7½ lb. cyanide per ton.

Oil concentration followed by cyanogen bromide treatment of the tailing gave an extraction of 96% from heads assaying 3.48 oz. gold.

Chlorination by leaching, using an aqueous solution of chlorine produced by bringing together an 0.8% sulphuric acid solution, and a 0.7% chloride of lime solution, and leaching 36 hr., gave a recovery of 40%.

Chlorination by the barrel process, after four hours' treatment, yielded 78 per cent.

These various methods were tried before wet concentration, because the aim was to treat all products on the ground and avoid shipping. A combination of concentrating and cyaniding, however, was ultimately considered the most suitable to Goldfield conditions, and was adopted.

The ordinary concentration of 30 or 40-mesh product was found ineffective. It did not make a close saving of the fine sulphide, which had to be removed on account of the poor cyanide recovery from the raw sulphide. It was necessary to evolve some closer method of recovery which would leave nothing for cyanide treatment except the finest particles that might elude the most efficient concentrating machinery. The only way to accomplish this was by a series of reductions, and by following each stage by appropriate concentration. The sulphide freed at each stage of grinding was at once removed before the ore passed to the next and finer stage of grinding, and thus an unnecessary comminution was avoided.

The following mill test forms the basis of the method adopted in practice. The ore, assaying 3.01 oz. gold, was crushed in stamps to 30 mesh and passed over a small Wilfley concentrator. This yielded 6% (by weight) of concentrate, assaying 27.4 oz. gold. The tailing was re-ground through 60 mesh, and re-concentrated; yielding 2.11% concentrate, assaying 19.8 oz. gold. The 60-mesh tailing was re-ground through 100 mesh and concentrated, yielding 0.4% concentrate, assaying 20.4 oz. gold. The residue was then ground to 200 mesh, and passed over a canvas table, yielding 10% of silicious concentrate, assaying 3.97 oz. gold. The final tailing from the above operation assayed 0.52 oz. gold, showing an extraction by concentration of 80%. The extraction by canvas alone was 13%, showing the marked adaptability of canvas to ore of this character containing so much extremely fine sulphide. Cyanide treatment of the slime resulting from this series of successive reductions and concentrations reduced the tailing to 0.22 oz. gold, making the total extraction 93 per cent.

This method was adopted because the required plant could be conveniently added to the mill already installed, and the same system of crushing used. Though a little complicated, the process was the least so of any of the methods considered. The high cost of fuel and supplies in Goldfield barred roasting. Besides, so long as the ore concentrated well, the advantage gained by segregating the roastable portion of the ore in small bulk was obvious.

The concentrate from the sulphide ore is now being shipped. It may later be treated by chlorination on the ground. The concentrate from the oxidized ore is about to be treated in the mill by fine grinding and prolonged cyanidation.

THE SEARCH FOR DIAMONDS.—Never before in the history of the United States has there been such a demand for diamonds as there was in 1905. Large quantities were imported, but the country produced none. In 1903 it produced diamonds to the value of \$50, in 1901 it had an output worth \$100, in 1900 its production was valued at \$150 and in 1899 the country boasted native diamonds to the value of \$300. Diamonds have been discovered in the United States in four different regions, but their actual place of origin is in every case unknown. All have been found in loose and superficial deposits, and all accidentally. It is not at all improbable, however, that some day the original sources of this queen of gems may be discovered.

GEOLOGY is every day assuming a greater importance in mining, but among its fundamental conceptions there must be no confusion between what is certain and what is more or less probable.

Coal Production.

According to the report of Edward W. Parker, Statistician of the United States Geological Survey, which is now in press, the production of coal in 1905 amounted to 392,919,341 short tons, having a value at the mines of \$476,756,963, surpassing in both quantity and value all previous records in the history of the country. Compared with 1904, when the production amounted to 351,816,398 short tons, valued at \$444,371,021, the output in 1905 exhibits an increase of 41,102,943 short tons, or 11.7% in quantity, and of \$32,385,942, or 7.3% in value. Prior to 1905 the maximum output of coal was obtained in 1903, when the production amounted to 357,356,416 short tons, valued at \$503,724,381, compared with which the record for 1905 shows an increase in production of 35,562,925 short tons, and of \$26,967,418. The high value recorded in the statistics for 1903 was due to the somewhat abnormal inflation of prices, caused by the shortage of fuel supplies, which resulted from the strike in the anthracite region of Pennsylvania in the preceding year. The lower values in 1904 as compared with 1903 were simply a return to normal conditions, but the decline in 1905 was the result of a production in excess of market requirements, unusually large as they were.

Of the total production in 1905, 69,339,152 long tons (equivalent to 77,659,850 short tons), were Pennsylvania anthracite, with a value at the mines of \$141,879,000. The total production of bituminous coal and lignite was 315,259,491 short tons, valued at \$334,377,963. The production of anthracite coal in Pennsylvania in 1905 was 4,020,662 long tons (or 4,503,151 short tons) more than that of 1904, while the increase in the production of bituminous coal and lignite was 36,599,882 short tons. A portion of these increases in both anthracite and bituminous production was due to the efforts of operating companies to provide a supply of fuel in anticipation of a suspension of mining in April, 1906, when the wage scale agreements in the organized coal producing States and the award of the Strike Commission in the anthracite region of Pennsylvania would terminate.

Of the total amount of bituminous coal produced in 1905, 103,396,452 short tons were mined by the use of mining machines, as compared with a machine-mined product in 1904 of 78,606,997 short tons. The number of mining machines in use increased from 7,663 in 1904 to 9,184 in 1905.

The total number of men and boys employed last year in the coal mines of the United States was 626,174, against 593,693 in 1904. Of the total number employed in 1905, 165,406 were in the anthracite mines of Pennsylvania, and 460,768 were employed in the bituminous coal mines.

The larger part of the increased production in 1905 was due to the great activity in the iron industry, as is shown by the fact that the amount of coal made into coke increased from 31,278,537 short tons to 42,412,328 short tons, and that the larger increases were in the coking coal producing States and those which furnished fuel to the iron furnaces.

A BOULDER 17 by 12 by 7 ft., weighing 60 tons, has been dislodged from the bed of the Nile by the powerful current issuing from the barrier at the Assouan dam and hurled against the masonry. The tremendous force of rapidly moving water is not generally recognized. It is estimated that the weight of solids which can be moved by a stream increases as the sixth power of the velocity; thus, a stream moving at 10 miles per hour can move 64 times the mass which can be moved by a stream at 5 miles per hour.

Three Weeks in Mexico---VI.

Cyanide Practice at El Oro.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

A few scattered notes on El Oro mill may be worth recording. The bolts of the battery-frames are coupled by washers; these are 6 to 10 in. long and from $2\frac{1}{2}$ to 3 in. wide; they connect two bolts and hold them firm. If one gets loose, the other holds it in grip and prevents movement.

The guides are made at the company's foundry, of cast iron; instead of being sectional with bolts, they are one solid piece. Each stamp has its own guide and a right-angle plate, to keep it in proper place and line. The wear is slight and therefore the stamp works smoothly; there is less heating than with wooden guides.

Elevator-Wheel and Cyanide Vats. El Oro Mill.

The mortar is a development of the anvil-block. This is an excellent mode of construction, if properly done. I know of one case—not in Mexico—where trouble was caused by the anvil-block being constructed so that it did not rest perfectly true on the cement foundation; to remedy this it was the custom to shim the concrete block with a little cement; when this last broke and crumbled, there was a movement of the mortar itself. At El Oro, the mortar-block is made extra heavy, combining to some extent the anvil in itself, with a base three feet wide and a bottom 13 in. thick; this is placed upon a concrete foundation, with a piece of quarter-inch rubber belt between.

At El Oro, cones are superior to spitzkasten; the sizing tests have proved this abundantly, the separation by the cones being much sharper. The circulation and agitation of slime are aided by six pumps which are the Butters modification of the Gwynne pump, such as is used in the London dock-yards. They are of the centrifugal type; compressed air is introduced to effect aeration of the solution. The chief advantage of the Butters modification is that all wearing parts are readily removable. Each pump makes 1,300 rev. per min. and in that period handles $4\frac{1}{2}$ tons ($3\frac{1}{2}$ tons being solution) of slime.

The vats are all made of steel plates, $\frac{3}{16}$ in. thick on sides, with $\frac{1}{4}$ -in. bottoms. Redwood laid down at El Oro comes to the same cost, but the steel is more durable

and makes a tighter vat in the climate of central Mexico. The vat does not dry if empty, there are no staves to check, and no absorption of solution.

In the precipitation house, there is used a device introduced independently by W. K. Betty in South Africa and by Alfred F. Main at El Oro; I refer to a drop-drip of KCy ($2\frac{1}{2}\%$ solution) over the head compartment of each zinc-box that is precipitating from the weakest solution, namely, that coming from the treatment of slime. This drip makes the zinc more active, so that a precipitation of precious metal is obtained in a manner usually unattainable from so weak a solution, that is, one containing only 0.02% KCy. Still weaker solutions are successfully precipitated in which the quantity of KCy is so small as not to be detected by the ordinary silver nitrate test.

The method of dipping the zinc shaving in lead acetate (to aid precipitation) is not employed at El Oro because lead acetate is used at another stage of the process, as already explained. Zinc fume was tried, but it was ineffective with such weak solutions. Great care is taken with the zinc shaving, to cut it in thin but tough filaments, not so crinkly as to break easily in handling. The shaving is laid in the boxes most carefully, so as to avoid channeling. El Oro plant is the only one of its size where acid treatment is not used. From the boxes the zinc is sent through launders, to be carefully screened, while it is also being washed with fresh water. Then it is pumped into two filter-presses until they are full, the charge being

equivalent to 19,000 oz. of bullion. The effluent solution is returned to the sump, the cakes in the press are washed and then dried by steam, the steam heating the iron of the frame sufficiently to dry the cake inside. The cakes are dried to such a consistence as will facilitate fluxing before briquetting; they fall into a car and are then mixed with the fluxes needed for melting; the mixture is fed into a briquetting machine, making round bricks $3\frac{1}{2}$ in. thick with 3 in. diam. These are dried before being thrown into the melting pot, from which bars of 1,000 oz. are cast. The Mexican workmen are compelled to remove their clothes after work, before passing to the outer room. The precipitation room has a cement floor and the furnace has a dust-chamber.

The development of milling at El Oro emphasizes the relative importance of the cyanide annex in the modern wet treatment of precious-metal ore; the annex to the new mill required an expenditure a little over twice the cost of the new 100-stamp mill itself. The tendency is to increase the percentage that is re-ground, the perfection of the extraction being closely determined by the fineness of comminution. At the time of my visit the aim was to make two products; sand, as near 150-mesh as possible (and a decreasing percentage even of that) and slime, that is, all below 200-mesh. Of course, the sand, even when re-ground, is different from the clay despite equality in

size of particles; the grains of 'sand' are sharp as against those of a mud (slime) rendered impalpable by absence of sharp edges. 'Sand,' however fine, filters well, while 'slime' will not filter at all; it packs like glue. On the other hand, by reason of the relatively larger surface presented by minute particles, chemical action on the precious metals is almost instantaneous. How necessary re-grinding is, was shown by a simple experiment made by Mr. S. H. Pearce. Sand, after ordinary cyanide treatment at the old mill, where there is no re-grinding, was dissolved in *aqua regia*, but the 'purple of Cassius' test, with stannous chloride, gave no precipitate whatever, the gold being effectively locked within the grains of

Which of these two sands is the finest? Caetani answers the question from the economic point of view, thus : It is desired to know the fineness of a sand for the reason that the finer the sand, the better the extraction obtained. Therefore the maximum possible extraction on a sand of given composition is a number proportional to its fineness, considered from an economic standpoint. As at El Oro one can *a priori* calculate exactly the extraction from a sand when a sizing test has been made, therefore one can calculate the index and represent thereby with one number what would otherwise have to be indicated by a tabulation consisting of 14 numbers. In the examples quoted at the beginning of the

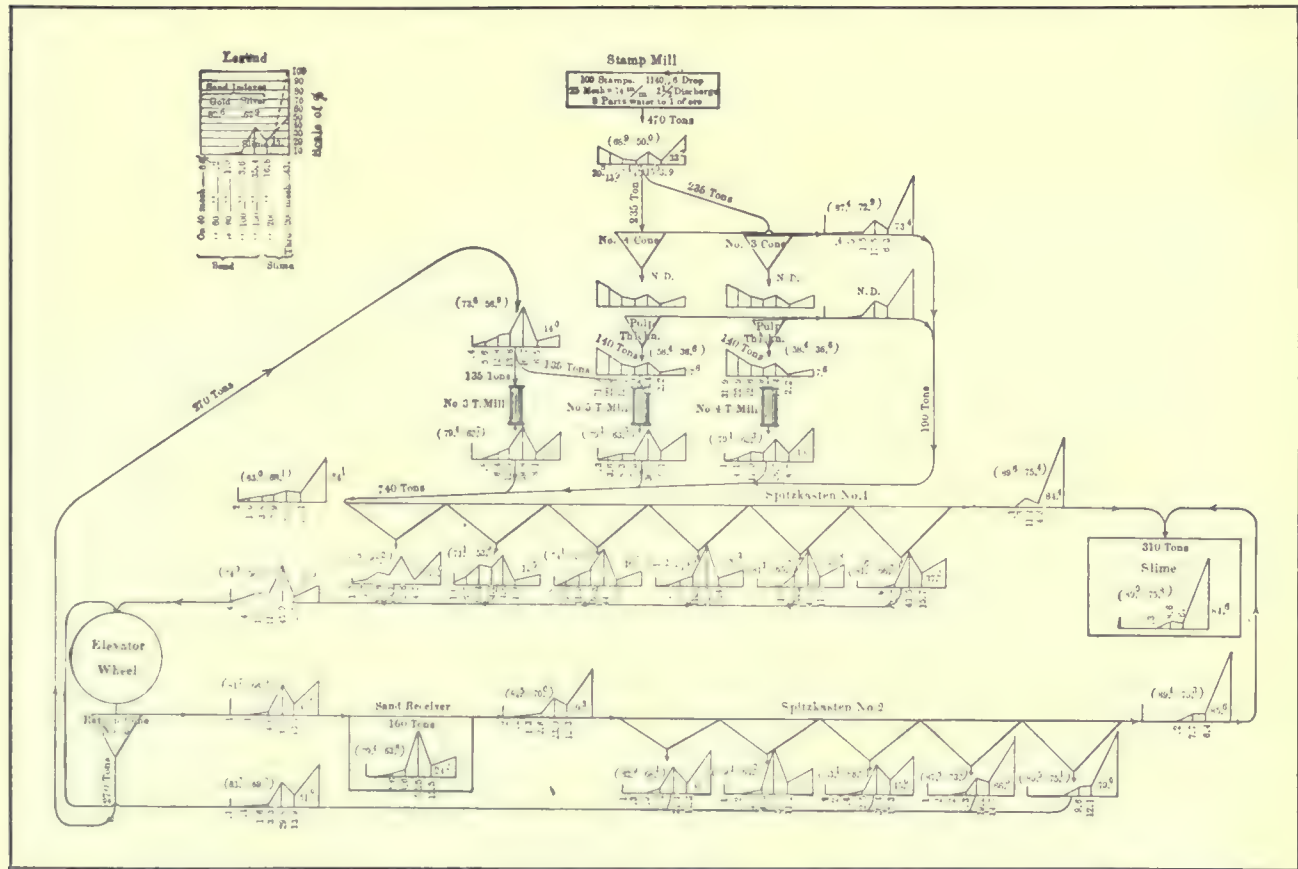

Fig. 2.—Diagram of Sizing-Tests at Mill No. 2. (September 1, 1905.)

sand. The assay of the sand gave \$4.50 per ton. Hence the need for re-grinding.

The accompanying record of tests will prove interesting to those engaged in cyanide work. Looking at Fig. 2, it will be noted that the legend explains the graphic representation of two sizing tests. At the time of these tests, a 2½-in. chuck-block was used, but it was too low to have much effect on the degree of fineness of the product; during the test the stamp-discharge was as through 28 mesh. Under these conditions the load on the tube-mills and on the plant became too heavy, so that finer screens were substituted shortly afterward. In the diagram (taken from the paper by Caetani and Burt, already mentioned) the ordinates represent the size of the screen and the abscisse the percentage retained on each of the screens. In the legend "Thro' 250 mesh" should read "through 200 mesh."

The use of the term sand-index, to be seen in the note appearing on the diagram, requires explanation. Caetani and Burt employ it, and it represents one of the most valuable features of their paper. The problem was the following. Given two sands of the following analysis:

Mes	on 20	on 40	on 100	On 200	Through 200 or slime
1st sand	10	30	25	5	30
2nd sand,	5	15	45	15	20

paragraph, the second sand is finer than the first, although it contains less slime.

REPORT OF CYANIDE DEPARTMENT, SEPTEMBER, 1905.					
MILL NO. 1.					
Classification	Tons treated.	Gold		Silver	
		Assay value	Indicated extraction.	Assay value	Indicated extraction.
Coarse Sand	20.23	2.562	9.46	51.33	1.73
Fine Sand	25.57	2.233	7.86	72.14	1.57
Slime	45.20	3.947	9.04	93.58	2.03
Total	100	8.732	8.86	76.50	1.83
REMARKS.—Old mill built before re-grinding was adopted. Fine sand poorer than coarse because it contains less gold open to attack. Slime richer in silver by presence of sulphide.					
MILL NO. 2.					
Sand	24.12	2.527	8.28	83.94	1.59
Slime	75.88	7.949	7.68	92.45	1.64
Total	100	10.476	7.82	90.28	1.63
REMARKS.—New mill includes systematic scheme of re-grinding, as shown by increased proportion of slime. Better extraction on slime raises general result to a satisfactory figure.					

The Esperanza mill had 120 stamps when the present company took it over, in 1904. It was deemed advisable to increase the capacity at the least possible cost, so 15 Huntington mills (each of 5-ft. diam.), were added, with the idea of re-grinding before cyanidation. This was

tried, but it was found necessary to place the Huntingtons above the stamp-batteries, which necessitated elevating the pulp. It being therefore difficult to distribute the pulp to the Huntington mills, it was finally decided to use the latter machines for first grinding, in association with, instead of in succession to, the stamps.

The crude ore passes over a 1½-in. grizzly before it reaches the rock-breakers; after being crushed by them, the ore goes over a ¾-in. grizzly, the undersize being allotted to the Huntingtons and the oversize to the stamps. The batteries are provided with 60-mesh screens; while the pulp issuing from the Huntington mills goes through an angle-slot screen equivalent to 60 mesh, but 65 % of the product will pass 200 mesh.

Of the 15 Huntingtons, six are now used as first grinders on low-grade sulphide ore, the product being sized

there is a great gain in the capacity of the plant without interference with effective percolation. A vacuum-pump, for withdrawing the enriched solution, is used only at the close of the operation. Sodium cyanide, NaKCy, is the chemical employed; it is guaranteed equal to 125 % active KCy, ranging from 124 to 128 %. The enriched solution, before precipitation in zinc-boxes, is rarely higher than \$2.20 in gold. Fresh cyanide, in crystals, is added to the head of the zinc-boxes, sometimes in quantity sufficient to keep the solution up to standard strength.

There are no amalgamating plates, and no mercury is used in the Esperanza plant. This is an interesting divergence from El Oro practice.

During September, 1905, the output of the mine consisted of 5,280 tons of shipping ore and 12,000 tons of milling ore, having together a value of \$780,385 U. S.

Esperanza Mine and Mill, El Oro, Mexico.

and distributed to six Wilfley tables, the tailing from which, after classification, passes down blanket sluices before finally reaching the cyanide vats. The concentrate from the Wilfleys and that washed from the blankets, goes to the smelter at Aguascalientes.

The other nine Huntingtons treat oxidized ore, which, after being ground, goes to the cyanide annex. The cost of steel and repairs to wearing parts amount to 34 *centavos* per ton; labor averages 15 to 20 *cr.* per ton. The muller shells and die-ring are made of rolled steel manufactured by the Midvale Steel Co., of Philadelphia. This is a soft metal and is susceptible of being kept to shape; it can be used until worn out, and is, therefore, economical. Each Huntington mill has its own motor; it has proved itself to be the best machine for reducing the ore to a certain point—say, 60 mesh—beyond which, for finer grinding, it is not economical.

The sand undergoes treatment for 100 hours; for it is found that extraction ceases then. Aeration is effected by a perforated pipe discharging over the return-solution vat; yet there is no such loss of KCy as might have been expected. The former collecting vats are now used for treatment; there is less aeration and less mixing, but

currency. The extraction in the mill was 91.64 % of the gold and 52.92 % of the silver in the crude ore.

At least \$150,000,000 of foreign capital was invested in enterprises in Mexico during her first year as a gold-standard country, about one-half of it American, the rest largely French and Canadian. Most of the new American capital was invested in railroad construction, mines, smelters, reduction works, and plants for the treatment of custom ores; timber tracts, agricultural lands, city real estate and mercantile enterprises. Our holdings in Mexican mines were increased by something like \$25,000,000. Our total investment in enterprises in Mexico is now \$600,000,000 in round figures. At the rate of increase at present indicated it will soon reach the \$1,000,000,000 mark.

THE scientific man accepts his limitations and does not expect to arrive at absolute verity. He observes; and when he has advanced far enough to begin to generalize, he formulates his ideas as an hypothesis to serve as a basis on which to work until someone has suggested something better.

The Value of Detonating Caps in Blasting.

By ROLAND L. OLIVER.

(Continued from Page 386).

*It is the nature of the initial detonation to the powder around the cap which governs the greater or less effect of the explosion of the whole charge. The cap communicates to the first particles of powder a disruptive impulse, which, according to the nature and strength of the cap, more or less completely overthrows their equilibrium and decomposes the powder with great energy, setting up sympathetic vibrations that explode the particles of powder in turn by the violent disturbances or friction between them in a regular succession of impulses and decompositions, which, if started with sufficient energy, are of such intense heat and velocity that the rupturing force of the explosive is developed practically instantaneously. This detonation has already been shown to be not only the result of mechanical force, but a combination of extremely sudden chemical and dynamical reactions which set up vibrations to which dif-

ferent powders are more or less susceptible, and these explosive reactions will be propagated through the mass of the powder according to the intensity of the vibrations and the resistance with which their motion is opposed by the nature and consistency of the powder, whether it be difficult or easy to oxidize, soft and plastic like dynamite, or hard. If the initial detonation of the powder surrounding the cap is of the highest degree, the vibrations will be most intense and will be propagated further through the mass than by a poorer detonation. Hence the different degrees of detonation. Unless the first particles of powder are so thoroughly decomposed by a detonation of high order, or first degree, as to convey the necessary heat and energy to detonate the whole charge, the greatest force of the powder will not be developed. There will frequently be unbottomed holes or pieces of unexploded powder scattered about, or both, and the air in the mine will be contaminated with some obnoxious gases that have not been completely oxidized.

The accompanying illustrations are from cross-sections of explosions in solid lead cylinders, and represent graphically the difference in force developed. Fig. 13 is a good detonation from a strong cap. Fig. 14 is a poor detonation from a weak cap in the same quantity of powder.

Some powders may lose as much as 20% of their effectiveness unless fired with a suitable cap. No. 1 dynamite poorly detonated is less effective and more obnoxious than No. 2 dynamite thoroughly well detonated.

A good rule is: "Better to use a cap of a grade too strong than a grade too weak." The strongest cap is

always best adapted to the longest hole, and other varying conditions about a mine, and is therefore the most economical.

It is customary to speak of caps as being of different degrees of strength. This is correct, but bear in mind that it means more than the mere mechanical force attained by different quantities of any particular detonating substance. It is the power or ability of that detonating substance by its peculiar dynamical and chemical nature instantly to transform an explosive into a state of great energy, and it has been shown in the early part of this paper that equal parts of some detonating substances possess this power immensely more than others.

Different brands of blasting caps contain different detonating mixtures, but they are supposed to be numbered or graded according to their detonating power, regardless of the weight of explosive which they contain. It was the custom in early days of dynamite to grade caps according to the weight of straight fulminate of mercury which they contained, because Nobel, the discoverer, found that a gun or rifle cap, which contained only half a grain of fulminate, would partially explode

straight nitro-glycerine, and that its explosive force was increased in proportion to the increased weight of fulminate up to 5 grains, which seemed to get the maximum energy out of this particular explosive. But other explosives required still more fulminate, some up to 30 grains or more, according to the length of charge to be detonated. Whenever fulminate of mercury is used, it must be incorporated with other ingredients to make the cap safe to handle. Some of these ingredients lessen its detonating effect, others intensify it, so the effects from given weights of fulminate have always been referred to as standards for different grades.

Though desirous of avoiding reference to any particular brand of caps, it is well to emphasize the fact that as their cost is small compared with the cost of drilling and preparing holes, none but the very strongest and best detonators should be employed. Consider first the powder and conditions under which it is to be used, then select a detonator which will develop the greatest energy out of that particular powder under these conditions. Properly made detonators, if not tampered with, should be safe to handle regardless of their strength.

Electrical fuses or exploders are for firing blasts by electricity. This method is of advantage when a number of shots can be fired simultaneously, as by firing them all at once the entire combined strength of the explosive is utilized. It is also commendable because of its safety and certainty of action in submarine work, wet shafts, and other places. Electrical fuses are built into the blasting caps and form a part of them. (Fig. 8) They are sealed up air-tight and are as nearly water-proof as such things can be made without expensive rubber insu-

*A paper read before the California Miners' Association and published by the California Cap Company.

lation, but when handled with ordinary care may be used freely under water, except when very deep, in which case they require special insulation and reinforced cartridges.

No blasting cap, unless it be a wet one, will fail to explode if fire reaches it, and there is no reason why the fire should not reach it if the fuse is good and has been properly handled. Nevertheless, cap manufacturers, like other manufacturers, are blamed for failures in blasting and are called upon to investigate complaints, but, as a rule, the difficulties are traced to improper handling by the operator, generally unintentionally, sometimes through lack of proper instructions. By way of illustration, the following instances have been noted and their remedies suggested:

Caps have failed to explode although the fuse had apparently burned all right. Upon investigation it has invariably been found that the fuse had not been put all the way into the cap and it had been crimped hard near the end with one or other of the objectionable tools which make a groove around the shell and had choked the fire in the fuse so that it could not spit into the cap. (Fig. 6) Upon removing the old fuse and putting a fresh piece

into the same caps which had failed before, but crimping them with a broad-faced tool, every one has exploded. Hence, to avoid choking the fire in the fuse, always see that the fuse is pushed down into the cap as far as the composition and secured to the cap with a broad tool, making the flat compression around the shell. (Fig. 5) Avoid thin crimpers, which make a groove around the shell. (Fig. 4)

Why does a tool which makes a groove around a shell frequently choke the fire in the fuse, or cause the fire instead of spitting into the cap to break out through the fuse just above the cap? (Fig. 4) The familiar Chinese fire-cracker will serve as an illustration. It is a core of meal powder rolled up in many layers of paper and choked at the bottom. The burning powder reaches this choke and can get no farther, so it takes the line of least resistance, bursts through the side of the paper and makes the desired report. So it is with fuse; the choke weakens or stops the fire, according to how hard it is crimped and how near the choke is to the extreme end of the fuse. A broad crimping tool cannot choke the fire because it acts similarly to a vise, and any good fuse will burn through a pressure of 300 lb. in a vise.

There are a great many more tools on the market which have the thin crimping part than have the broad. The thin ones (Fig. 3) have been cheaper to get up, hence find a market, but invariably wherever replaced by a broad tool the most frequent source of misfiring has ceased. Why buy a poor tool and take such chances when 50 cents at most will buy a better and more practical tool?

Miners should be cautioned also about some combination crimpers and fuse cutters, because although many have the broad crimping, in some it is placed behind the cutting part. This is not a good arrangement, because the cutter comes in the most convenient place to nip the cap with when in a hurry and being sharp, not only makes a groove part way around the shell, but also breaks the shell and lets water into the cap. Bad results have been traced to this very thing; hence, operators desiring combination tools should be particular to use only those which have the cutter behind the crimping part. (Fig. 2) The broad crimping without any cutter is recommended because there can then be no mistakes made. Either a pocket knife or pruning shears make good fuse-cutters.

When the use of a crimping tool is suggested to some miners,

or when they hear of misfiring being caused by poor crimpers, they smile and tell how they get along by merely biting the cap to the fuse with their teeth. This is a crude method, but a positive admission of the necessity of fastening caps some way, or else these fellows would not take such a risk of putting dangerous things in their mouths. They also admit of occasional misfires due to caps slipping away from the fuse when they didn't bite hard enough, perhaps, and all are familiar with 'miners' headaches,' taking them as a matter of course, even after losing time waiting for noxious gases to clear after firing; hence these blasters have all this time unconsciously not been getting the best results out of caps and powder, because good crimping not only secures the position of the cap and keeps dampness out, but also serves as additional confinement to the fulminate, thereby developing greater power from the cap, which, as has already been shown, produced a correspondingly increased result from the powder.

Other instances of complaint have been noted where the end of the fuse inserted in the cap had become damp. It had burned apparently down to the cap, but in so doing had forced the hot moisture into the cap, thereby not only moistening the fulminate, but weakening the spit of the fire from the fuse. Damp fuse has been observed to burn a few feet and then slow down or hang fire and sometimes to go out. Cutting off the burned part immediately and re-lighting, the remainder burned a few inches and again went out, and so on through the whole length, showing conclusively that the heated dampness steamed the powder enough to weaken, and at times to

put out, the fire. The remedy is as follows: Fuse should not be left lying around in a damp place; but if it has had to be for a short while, cut off a few inches and throw the piece away, or, having cut off the desired length for the hole, always put the freshly cut end into the cap. Of course, caps must be kept dry also.

The question has been asked, "Why should fuse so well protected with waterproof covering dampen so readily?" Because the meal powder in the fuse is hygroscopic, drawing moisture from the atmosphere. Also, the yarn core along which the powder is strung is dry and spongy, so that both the powder and yarn will draw moisture a long way into the fuse. That this moisture is driven ahead of the fire in the fuse, steaming and weakening it, has been demonstrated in still another way by placing one end of the damp fuse in a cold glass tube and observing the large amount of water vapor condensed in the cold tube. Dry fuse will spit fire several inches into the tube and the glass will be comparatively free from water, but damp fuse will only spit very weak fire, if any at all, and the cold glass tube will be wet with drops of condensed steam from the fuse, the amount of moisture increasing with the length of fuse burned.

In other instances blasters have smeared double-tape fuse with vaseline, others with axle grease or crude oil, when working in wet ground, intending to make it waterproof, and these oils being solvents of tar had penetrated through the tar into the core of powder in the fuse and spoiled it. The quantity of volatile tar products from the burning fuse may also be observed in the glass tube mentioned above by a brown stain which their condensation will make. Soap, clay or tallow will protect the fuse for a short time, but these occasionally get chafed off when pushed into the hole or during tamping. Candle grease is often used and is efficient, but care must be taken not to apply it too hot. The safer and better way in such cases is to use triple-tape or other waterproof fuse in wet ground, and secure the cap with a broad crimper, or wrap about four inches of electricians' adhesive tape over the junction of cap and fuse. (Fig. 9) In very wet ground it is often expedient to use electrical exploders. (Fig. 8)

Unbottomed holes, 'sinkers' and premature blasts are sometimes complained of. These have been found to be cases either of using too low a grade of cap for a particular kind of powder, spoiled powder, uncaredful loading, or hole cut off by a previous shot.

The proper choice of detonator will remedy the first cause: 3x or 4x caps are recommended for straight dynamites when not frozen; 5x, 6x or 'lions' for gelatine dynamites, chlorate mixtures and all other inert powders. In cold weather, nitro-glycerine powders become less sensitive; the strongest cap is then especially recommended, as it will get most work and least fume out of any powder, even under unfavorable conditions.

The second cause requires more careful storage of powder. Nitro-glycerine evaporates perceptibly at a temperature of 100°, so that the powder will become weakened and inert. It freezes at about 42°, becoming hard, inert and dangerous. In a damp place it will absorb moisture, which displaces the nitroglycerine, and if stored there for any length of time will become spoiled. Hence dynamite should be soft and dry, stored in a dry and cool place.

As for the third cause, premature blasts, smoky blasts, and weak shots frequently result when the cap is buried way down in the mass of the charge, because the fuse in burning down, and before reaching the cap, may prematurely ignite the powder by side spitting or even by its own heat, and burn up part of it before the rest explodes. (Fig. 11)

Even in preparing a short piece of cartridge as a primer

it is bad practice to push any of the fuse into the powder, especially if it is cotton covered, as this absorbs nitro-glycerine rapidly, which, if injected into the cap, greatly weakens its explosive force, and sometimes causes mis-fire.

Side spitting is not always the fault of the fuse. In rough handling it may have become kinked and the tape cracked or weakened at that place so that it blows out of the side of the fuse. Hence, never bury a cap and fuse beneath several sticks of powder. The cap must, however, be in actual contact with the powder, hence the advisability of always tying the cap and fuse into the last stick of powder placed in the hole (Fig. 12), so that the powder cannot slip away from the cap, in which event there would either be tamping or an airspace between the cap and charge, both of which cause mis-shots or bad fumes in the mine, because when the cap gets separated from the powder it cannot possibly exercise its full detonating effect.

In view of the importance of the facts which have been brought forward, a summary is offered, not with a desire to dictate hard and fast rules to those who are breaking ground nearly every day of their lives, but in the form of brief and specific suggestions to insure more thorough detonations of powder and best results.

First—Select the right fuse for the kind of work, and proper caps for the kind of powder in use, and see that both are thoroughly dry.

Second—Powder must not get shaken out from end of fuse, nor sawdust or other obstruction get in between fuse and cap composition. Cutting fuse slanting not only allows a little of the powder to shake off, but often makes an obstruction to the fire because the slender end may fold under. (Fig. 7) Also a sharp-pointed piece of fuse is not a desirable thing to thrust into any cap.

Third—Cut the fuse straight across, not slanting, and push it into the cap half an inch or more, all the way down to the powder. (Fig. 5) If the fuse be ragged at the end or too large to easily enter the cap, never peel off any of the tape or yarn, but swage the end of the fuse to the proper size. This may be easily and quickly done by twisting and squeezing the large part with the crimper (Fig. 1), if it be a broad one. Having inserted the fuse, squeeze the shell tightly to it with a broad crimper placed around the shell so that one side just overlaps onto the fuse. This will make a compression about a quarter of an inch wide around the extreme upper end of the shell.

Fourth—The blasting powder should not be cold, much less frozen, and holes should be carefully charged, squeezing each cartridge separately with a wooden rammer so as to completely fill the hole to the desired height.

Fifth—Having crimped the cap securely to the fuse, insert all of the cap—but none of the fuse—into a stick of powder and tie together (Fig. 10); then put this priming stick upon the rest of the powder in the hole (Fig. 12) and do not ram it until some loose sand or other tamping has been put in. Use tamping without any sharp rocks in it so as not to damage the fuse.

Sixth—Wherever a whole blast may be fired at once, and for all work in very wet places, electrical fuses will be found of advantage.

In conclusion, it is hoped that the subject of detonation as applied to the common blasting explosives has been made more clear and that the facts which have been brought forward show how detonating caps determine the value of the blasting powder which they are used with, and also that oftentimes the fuse, caps and powder are unjustly blamed, whereas if the operator attends more closely to the apparently insignificant, but very essential details referred to, many fruitful sources of danger, as well as much trouble, worry and expense, would be avoided.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

ORE-SEPARATOR.—No. 829,959; William B. Frantz, Lansing, Kansas.

In an ore-separator the combination with a rocking frame and a trough supported thereby; of a rotatable polygonal wheel, a column supported by the frame, a cushion thereon contacting with the wheel, said wheel adapted to vibrate the column and frame, and a trough carried by the frame and movable therewith.

METHOD OF SMELTING ORES AND SEPARATING MATTES.—No. 830,040; Ralph Baggaley, Pittsburg, Pennsylvania; Charles M. Allen, Lo Lo, Montana; and Edward W. Lindquist, Chicago, Illinois.

The method of separating matte, which consists in supplying molten matte and ore to a converter, blowing air therethrough, and discharging the resultant matte and slag into a separate chamber and therein separating the matte from the slag.

SPUD FOR DREDGES.—No. 830,079; George W. King, Marion Ohio.

In a dredge of the character described, a hull having spud-guides; provided with wearing-plates along the mar-

gins of their opposite faces, in combination with a spud consisting of a box-girder with recessed sides, said spud having angle-bars secured thereto and presenting guiding-surfaces to co-operate with the wearing-plates of the guides.

APPARATUS FOR TREATING SLIMES AND SIMILAR MATERIALS.—No. 830,388; William T. Weekley, Kalgoorlie, Western Australia.

The combination of a frame having thereon an upper filter-tray and a lower filter-tray, and means for transposing the trays at intervals to drop material from the first-named tray.

HOT-AIR SYSTEM FOR BLAST-FURNACES.—No. 830,152; Thomas Kiddie, Ladysmith, Canada.

In a device of the class described; the combination with a blast-furnace flue or dust-chamber, of a thin metal pipe extending lengthwise therein, such pipe having in cross-section a width relatively less than its depth and a downward-sloped upper side, means providing for the longitudinal expansion and contraction of the pipe, means for admitting the air of the blast into the pipe at one end, and means for delivering the heated air to the furnace from the other end.

Aspco.

Nitro-glycerine compounds for blasting were introduced in the mining industry nearly forty years ago. They were not kindly received by the miners generally, nevertheless their superiority as a blasting agent was quickly recognized and black powder soon became a thing of the past in most mines. Nitro powders had many things to recommend them. They were compact, they were surprisingly powerful in rending rock, and, on the whole, they were vastly superior to black powder. They were made of varying degrees of strength, from practically pure nitro-glycerine, extremely dangerous to handle, down to the well known 'low powder' used in outside heavy work. Nitro powders became popular, and they are today the most extensively used of any blasting compounds in the world. But the miner, while appreciating the value and convenience of the various makes of nitro-glycerine compounds, such as Giant, Hercules, Judson and a dozen other kinds, is equally wide awake to their disadvantages. He knows they are extremely dangerous to handle; that they freeze at a comparatively moderate temperature -40° F, and that their explosion fills the mine workings with fumes of nitrous oxide, which are not only disagreeable, but deadly if inhaled in large amount. A moderate dose of 'powder smoke' gives the unfortunate who breathes it a splitting headache, which no amount of medicine can remedy; the victim must have hours of sleep and rest before he is free from the evil effects of the powder gas, for most of the remedies recommended for 'powder head' are as bad in their effects as the nitrous oxide, being ruinous to stomach and nerves alike. There is also that nemesis of the miner—the missed hole. How many a good man has come to his end in the prime of health, with apparently years of usefulness ahead of him, by drilling or picking into a missed hole. Often a miner is heard to say, after one of these sad accidents, which has taken one or more of his comrades: "If we could only get a powder that is the equal of dynamite, without its fumes and danger in handling; that won't freeze and is as easy to use as nitro-powder; but I guess we want too much." Not at all. There is just such a blasting compound now being placed upon the market, an innovation in high explosives. One that is perfectly safe to handle, lighter in weight, bulk for bulk, than any dynamite; it won't freeze, nor melt at any atmospheric temperature. A rifle-ball can be shot into a box of it with perfect safety; it leaves no noxious fumes of any kind, and the miner can return to the face of a close drift immediately after blasting without encountering deadly gases, or running danger in any way; and if there has been a missed hole, all he has to feel concerned about is the detonating cap, which is the only thing that will explode this new product. The hardest granite or greenstone, the softest sandstone or shale, are blasted by it with equal facility. For 'bulldozing' and 'block-holing' it has no equal. It simply rends a rock into fragments fracturing it in all directions in a most remarkable manner. Mysterious and difficult of explanation are the physical demonstrations and potentialities of this most modern explosive. Considerable exploitation of this new powder has been made within the past two months at Los Gatos, San Jose, and Berkeley, California, one of the most notable ones of recent date, having taken place on September 21, at Berkeley in the presence of a large number of mining and scientific people, well known on the Pacific Coast.

This new explosive has been named ASPCO, a trade name distinctively characteristic, and suggestive of the manufacturer, The American Safety Powder Co., a California corporation, composed of men identified with the mining industry. An economic feature of ASPCO is the fact that it can be shipped at merchandise rates, which will very materially reduce the item of mining costs. George W. Myers of Berkeley, California, for several years the Coast representative of Masurite, a safety powder with an excellent Eastern reputation, has been appointed the contracting agent for this twentieth century product.

Books Received.

THE PROSPECTOR'S FRIEND is the title of a little book issued by the Way's Pocket Smelter Co., of South Pasadena, California. It contains a description of the Way 'tablet,' used in making metallurgical determination of ore, and other information useful to the prospector. The tablet is said to operate satisfactorily on the ores of gold, silver, copper, tin, lead, zinc, etc., and the determinations are quickly made.

COBALT AND ITS SILVER MINES, is the title of a well-illustrated book by W. S. Bullock, 25 Broad street, New York City. Cobalt has probably attracted more attention than any other one mining camp in the world during the current year. This work describes and illustrates the mines and gives much valuable information about the district, the mining laws, and a list of the most important companies operating there. Price, 25 cents.

From the UNITED STATES GEOLOGICAL SURVEY, Professional Paper No. 50. The Montana Lode of the Keewatin Ice Sheet, by Fred H. H. Calhoun; Bulletin 275, State Deposits and Industry of the United States; No. 277, Mineral Resources of the Kenai Peninsula, Alaska; No. 278, Geology and Coal Resources of the Cape Lisburne region, Alaska; No. 280, The Rampart Gold Placer Region, Alaska, by L. M. Prindle and Frank L. Hess; No. 281; No. 282, Oil-fields of Texas and Louisiana; No. 288; No. 291, A Gazetteer of Colorado; also water supply papers No. 155, 156, 158, 163, 173, 176, and 178.

Commercial Paragraphs.

THE CHICAGO PNEUMATIC TOOL CO. has opened an office at 1012 Memphis Trust Bdg., Memphis, Tenn., in charge of J. Francis Small.

HARRON, RICKARD & MCCONE have established their headquarters at 316 Market St., San Francisco. The warehouse at 7th and Berry St. will be retained as heretofore.

The newly designed SIMPLEX CONCENTRATING TABLE, manufactured by the Colorado Iron Works Company, has a strong, easily adjusted, differential motion, that imparts the proper impulse to the ore along the riffles, and the stroke may be readily shortened or lengthened according to the speed at which the pulp is required to travel toward the discharge. A highly silicious ore that requires longer time to stratify, needs the slower motion obtained by the shorter stroke. The table has three decks, each deck having a riffled rubber surface, and each deck may be independently adjusted as to side slope. This enables the operator to gauge and control the flow of the gangue over the riffles, making it as rapid as possible without carrying the mineral over with it. Each deck is a separate concentrator and may be adjusted to suit its own work.

AMONG the orders for machinery reported booked by the POWER AND MINING MACHINERY CO., Cudahy, Wis., may be mentioned the following: Twenty-four sets of 36 by 16 in. crushing rolls, and four sets of 54 by 20 in. crushing rolls for the Utah Copper Co., Garfield, Utah; three additional converter stands and nine shells for the Detroit plant of the Copper Queen Con. Mining Co., at Morenci, Arizona; eleven 6-ft. Chilean mills for the Real del Monte y Pachuca, Pachuca, Mexico; six 6-ft. Chilean mills for the Golden Cycle Mining Co., Colorado City, Colorado; sixty agitators for the United States Mining Co., Salt Lake City; three 48 by 240 in. water-jacketed copper furnaces for the British Columbia Copper Co., Greenwood, B. C.; three 56 by 240 in. water-jacketed copper furnaces for the Balaklala Con. Mining Co., Redding, Cal.; two 46 by 162 in. copper and lead furnaces for the Oaxaca Smelting & Refining Co., Oaxaca, Mexico; one 56 by 180 in. water-jacketed copper furnace for the Arizona Smelting Co., Humboldt, Arizona; two converter stands, electrically driven, and four shells 96 by 108 in.; also five 10-ton matte ladles, for the Selby Smelting & Lead Co., South San Francisco; four converter shells, 84 by 126 in., for the Colusa Parrot Mining & Smelting Co., Butte, Mont.; two converter shells, 84 by 126 in., for the Shannon Copper Co., Clifton, Arizona.

Editorial.

IN THIS ISSUE we publish a description of shaft-sinking as accomplished with small drills at the North Star mine. The details given by Mr. Arthur B. Foote, assistant superintendent of the mine, will be welcomed by practical men. One of the important economic gains made in mining during the last two or three years has been through the use of small one-man drills for stopping and even, as in this case, for shaft-sinking, in place of the big machines that require two men. The successful use of the small drills is dependent upon the character of the rock and, where that is neither excessively tough nor unusually soft, the only way to find out whether small machines can be substituted for the big ones is to make a trial under careful supervision.

THE TWO ARTICLES on the treatment of ore at the Combination mine will be appreciated by millmen. Mr. Francis L. Bosqui has described the development of the existing process of treatment through a succession of tests and trials from the very start, as the mine grew and the ore changed from an oxidized to a sulphide condition. This account of the practice and of the metallurgical principles involved has more than a local application, for high-grade quartzose gold ore of the same character is being found in many of the new districts of Nevada, the output of rich silicious material at the present time reminding one of the palmy days of Cripple Creek, when the smelters in Colorado became short of the lead and copper ore required for a good smelting mixture. We look forward to the completion of the San Bruno plant, at San Francisco, since these large reduction works will afford a market for the output of the Nevada goldfields, to be smelted with the copper matte from Shasta.

AS WE HAVE SAID on other occasions, this journal has nothing to do with politics, but it takes a keen interest in all that makes for good citizenship. It is a pleasure, therefore, to give a page to an extract from the notable address delivered by the President at Harrisburg. To those who may feel depressed at the general evidence of corruption in politics and in business, the President's appeal to the manhood of the country comes like a bugle call at dawn, awakening all the true patriotism and civic pride of the American people. As the MINING AND SCIENTIFIC PRESS finds many readers in countries outside the United States, it is gratifying to afford them an opportunity of reading the vigorous utterances of our Chief Executive, and when they read them, they are likely to realize that we have something more than an industrial community intent solely on the making of money. To Americans abroad, especially to our engineer friends in distant lands, the stirring notes of the President's address will come as a message from home.

Prevention of Fraud.

The most important topic of discussion on the program of the American Mining Congress, which meets at Denver next week, is the prevention of fraud in mining. It is proposed to draft a law for the protection of investors and the punishment of those who, under cover of mining operations, carry on a predatory business among the inexperienced. In this matter California has led the way, for the last Legislature passed an act, which has now become a law, making willful misrepresentation a felony, punishable by imprisonment, or fine, or both. It is claimed, with good reason, that California is comparatively free from the more vicious forms of mine promotion, and some of those in authority credit this honorable condition of affairs to the existence of punitive legislation. We would be glad to believe this, but, to be frank, we think it to be traceable to the absence of any speculative excitement in the western foothills of the Sierra Nevada. Fraud travels in the dusty wake of a boom and flourishes in the warm air of wild speculation. In Nevada there is lots of it just now, so also at Cobalt, in Ontario, not because of any particular depravity in the people on the deserts of the Great Basin or in those who dwell among the resplendent lakes and forests of Canada, but simply because the haste to get rich quickly deludes the victims that are sacrificed to financial piracy. In California mining is prosperous in a quiet and orderly way, the stock exchanges do not quote the shares in her productive mines, they belong to persons who are willing to hold their property and to work it, instead of the public. If any extraordinary discoveries, especially in a new district, were to be made, it is likely that even our people might take a hand in that game of mining speculation where the 'ante' is high, the play without a 'limit'—and the promoter takes the 'kitty.' It is notorious that new camps are the favorite breeding ground of fraudulent schemes. It is intended to hinder these, if not to suppress them, so that the widows and orphans, the simple and the greedy, may be protected. This is excellent, and we entertain no doubt but that the public discussion of the matter will be beneficial—even more beneficial than the proposed legislation. It is not special legislation that is required so much as the enforcement of that already enacted; there are plenty of laws on the subject, but they lie neglected, because it is difficult to determine at what point a man ceases to express his honest opinion and begins to act in bad faith. Moreover, the truth as to the condition of a mine is hard to ascertain, when anyone is bent on obscuring the facts. The American Mining Congress has undertaken to furnish investors with information about mines and to place the industry "on an investment rather than a speculative basis." Both these departures are well meant, but they are not to be taken seriously. Accurate information concerning a mine is only to be got by sampling and careful investigation, and everyone ought to know that the Congress can do no such work unless it is prepared to pay for the services of a corps of engineers, like those the exploration companies find it necessary to retain. Any opinion based on second-hand and gratuitous informa-

tion is worth usually what it costs—nothing. As to mining being an investment and not a speculation, that is a fallacy of the first water, which it is easy to disprove. How many men would be willing to put their mining scrip in a safe and lock it up for five years, or even five months? Mining is a speculation, with the possibility of gains that warrant the risks; it needs no apology, and benefits not at all by being misrepresented.

We believe in two methods of stopping fraud in mining; the first is to prevent the misuse of the mails, and the other is an enlightened public opinion on the whole subject of mining speculation. The post-office inspectors are to be credited with two notable convictions—that of Letson Balliet and that of G. W. Rumble, and with much other useful work besides. To land such men in the penitentiary is difficult and it is expensive, but it is worth to the community all that it costs. We hope to see the postal authorities encouraged in their activity in this regard, and we consider that one of the most practicable ways of achieving the purpose under discussion would be to increase any appropriation that is made at Washington for rigid control of the mail service, to the end that a great public utility may not be put to base ends. This should apply especially to the newspapers that are made the medium for advertising fraudulent schemes. Next, we believe in the creation of an intelligent public opinion in these matters. Laws are bound to lie unheeded unless the community thinks strongly in regard to the infraction of them; there is no judge or jury that is insensitive to public sentiment. Therefore, let the widows and the orphans, the foolish and the needy, be informed that mining speculation is risky, particularly when undertaken without advice, that vultures are not rare birds, and that people who expect to make a dollar by placing ten cents must not whimper if they see their coin swept off the board. Moreover, let it be recognized that newspapers and journals which denounce mining frauds on their reading pages and advertise others just as bad on their advertising pages, are playing a double game. It is curious, it is even more than a coincidence, that the mining schemes which are advertised on the outside of such papers are never attacked on the inside pages. Again, let the poor widows and orphans, the gullible and the gambler, be informed that the photographic presentments of the organizers of mining companies do not indicate anything in particular. Why a promotor should think that his picture, even if he be handsome, should be accepted as proof of his honesty or of the richness of his hole in the ground, is for someone to explain. In general, the children in finance had better avoid companies that ask for support on the basis of such pictorial suggestion. There are many things that the Mining Congress can say authoritatively, and there is a lot of illumination that it can shed over the by-paths of predatory enterprise. Mining is good enough to stand the truth; when properly done it is the most profitable form of industrial activity, and it will do no harm to divert some of the capital wasted on hopeless holes to the development of sound undertakings. Every dollar mispent is so much lost to the fund that develops the real mineral resources of this country.

By the Way.

At the dedication of the new Capitol of the State of Pennsylvania, at Harrisburg, on October 4, the President, Mr. Theodore Roosevelt, said:

We can show that the past is with us a living force only by the way in which we handle ourselves in the present, and each of us can best show his devotion to his own State by making evident his paramount devotion to that Union which includes all the States. The study of the great deeds of the past is of chief avail in so far as it incites us to grapple resolutely and effectively with the problems of the present.

We are not now menaced by foreign war. Our Union is firmly established. But each generation has its special and serious difficulties, and we of this generation have to struggle with evils springing from the very material success of which we are so proud, from the very growth and prosperity of which, with justice, we boast. The extraordinary industrial changes of the last half-century have produced a totally new set of conditions, under which new evils flourish, and for these new evils new remedies must be devised.

Some of these evils can be grappled with by private effort only, for we never can afford to forget that in the last analysis the chief factor in personal success—and, indeed, in national greatness—must be the sturdy, self-reliant character of the individual citizen. But many of these evils are of such a nature that no private effort can avail against them. These evils, therefore, must be grappled with by governmental action. In some cases this governmental action must be exercised by the several States individually. In yet others it has become increasingly evident that no efficient State action is possible, and that we need, through executive action, through legislation, and through judicial interpretation and construction of law, to increase the power of the Federal Government.

If we fail thus to increase it, we show our impotence and leave ourselves at the mercy of those ingenious legal advisers of the holders of vast corporate wealth, who, in the performance of what they regard as their duty, and to serve the ends of their clients, invoke the law at one time for the confounding of their rivals, and at another time strive for the nullification of the law, in order that they themselves may be left free to work their unbridled will on these same rivals, or on those who labor for them, or on the general public.

In the exercise of their profession and in the service of their clients astute lawyers strive to prevent the passage of efficient laws and strive to secure judicial determinations of those that pass which shall emasculate them.

They do not invoke the Constitution in order to compel the due observance of law alike by rich and poor, by great and small; on the contrary, they are ceaselessly on the watch to cry out that the Constitution is violated whenever any effort is made to invoke the aid of the National Government, whether for the efficient regulation of railroads, for the efficient supervision of great corporations, or for efficiently securing obedience to such a law as the national eight-hour law and similar so-called 'labor statutes.'

The doctrine they preach would make the Constitution merely the shield of incompetence and the excuse for governmental paralysis; they treat it as a justification for refusing to attempt the remedy of evil, instead of as the source of vital power necessary for the existence of a mighty and ever-growing Nation.

All honest men must abhor and reprobate any effort to excite hostility to men of wealth as such. We should do all we can to encourage thrift and business energy, to

put a premium upon the conduct of the man who honestly earns his livelihood and more than his livelihood, and who honestly uses the money he has earned. But it is our clear duty to see, in the interest of the people, that there is adequate supervision and control over the business use of the swollen fortunes of today, and also widely to determine the conditions upon which these fortunes are to be transmitted and the percentage that they shall pay to the Government whose protecting arm alone enables them to exist. Only the Nation can do this work. To relegate it to the State is a farce, and is simply another way of saying that it shall not be done at all.

Under a wise and far-seeing interpretation of the interstate commerce clause of the Constitution, I maintain that the National Government should have complete power to deal with all of this wealth which in any way goes into the commerce between the States—and practically all of it that is employed in the great corporations does thus go in. The national legislators should most scrupulously avoid any demagogic legislation about the business use of this wealth, and should realize that it would be better to have no legislation at all than legislation couched either in a vindictive spirit of hatred toward men of wealth or else drawn with the recklessness of impracticable visionaries.

But, on the other hand, it shall and must ultimately be understood that the United States Government, on behalf of the people of the United States, has and is to exercise the power of supervision and control over the business use of this wealth—in the first place, over all the work of the common carriers of the Nation, and in the next place over the work of all the great corporations which directly or indirectly do any interstate business whatever—and this includes almost all of the great corporations. The Government ought not to conduct the business of the country; but it ought to regulate it so that it shall be conducted in the interest of the public.

It behooves us Americans to look ahead and plan out the right kind of a civilization, as that which we intend to develop from these wonderful new conditions of vast industrial growth. It must not be, it shall not be, the civilization of a mere plutocracy, a banking-house, Wall-street-syndicate civilization; nor yet can there be submission to class hatred, to rancor, brutality, and mob violence, for that would mean the end of all civilization. Increased powers are susceptible of abuse as well as use; never before have the opportunities for selfishness been so great, nor the results of selfishness so appalling; for in communities where everything is organized on a merely selfish commercial basis, such selfishness, if unchecked, may transform the great forces of the new epoch into powers of destruction hitherto unequalled.

We need to check the forces of greed, to insure just treatment alike of capital and of labor, and of the general public, to prevent any man, rich or poor, from doing or receiving wrong, whether this wrong be one of cunning or of violence. Much can be done by wise legislation and by resolute enforcement of the law. But still more must be done by steady training of the individual citizen, in conscience and character, until he grows to abhor corruption and greed and tyranny and brutality, and to prize justice and fair dealing.

The men who are to do the work of the new epoch must be trained so as to have a sturdy self-respect, a power of sturdy insistence on their own rights, and with it a proud and generous recognition of their duties, a sense of honorable obligation to their fellows, which will bind them, as by bands of steel, to refrain in their daily work at home or in their business from doing aught to any man which cannot be blazoned under the noon-day sun.

Special Correspondence.

London.

Siberian Ventures are Popular. — Particulars of Some of Them. —

Methods of Financing Mines. — The Golden Stream From Australasia. — Impressive Statistics.

Sundry reports and particulars concerning Siberian ventures have furnished the financial and mining press with a supply of welcome 'copy' during the slack holiday season. The industry is assuming considerable proportions, the promoting groups having been able to attract to their side names which stand well in both financial and social circles. As ground-work for future reference it will be useful to glance briefly at the various organizations in the order, as may be practicable, in which they have come into public notice. The Siberian Syndicate, Ltd., the shares of which have just been introduced on the market, has a nominal capital of £100,000, in 100,000 shares of £1 each. There are issued 50,000 shares, of which 8,574 shares are fully paid and 41,426 have 5s. per share paid up. It is not expected that more than an additional five shillings will be called up this year. The reserve is consequently £50,000, and it is added that "no options exist over these shares." The Siberian Syndicate was formed in June, 1905, to acquire the assets and good will of the previous syndicate of the same name, which had been continuously at work in Siberia since 1902, and which, in July, 1904, floated the Spassky copper mine. The other properties in which the syndicate is interested are stated to be numerous and to cover an enormous area. The principal are known as the Popoff and Atbasar groups of mines, respectively, upon which options have been secured. The Popoff group consists of 59 ore-fields, containing gold, silver, copper, lead, graphite, and coal mines, and two smelting works situated in the Karkaralinsk and Pavlodar districts of the province of Semipalatinsk, on the left bank of the river Irtysh, in southwest Siberia. The district is reached from London in about fourteen days. The reports of the syndicate's engineers are necessarily incomplete, in view of the enormous area involved; but, so far, they are considered by the consulting engineers, Pellew, Harvey & Fell, to be of a most encouraging nature. The Atbasar group consists of copper, silver-lead, and coal mines in the Kirghese steppes. The preliminary reports of the engineers on the copper deposits are said to be highly favorable. To allay any uneasiness in the minds of speculators as to the possible effect of the political unrest in the Russian Empire, it is pointed out that the properties in which the Syndicate are interested lie outside the revolutionary area. A proof of this may be found in the fact that the chief police department is so far able to occupy itself with the peaceable ways of commerce as to be in a position to inform the manager of the Spassky Copper Co. that the Government is commencing at once to construct the Orenburg-Amolinsk-Semipalatinsk railway. This railway should pass quite close to the Spassky copper and coal mines, and through the properties now being inspected under option by the Syndicate. With regard to the fortunes of Spassky copper in particular, it appears that a leading South African house has sent out its representative to examine it, with the time-honored object, doubtless, of exercising an option on a block of shares if the report is favorable. The story goes that the company—which is protected by an enormous duty on imports of copper into Russia—has recently secured a most advantageous contract to supply 200,000 poods at 16½ roubles, whereas it is estimated that the cost of pro-

duction will be only about 8 roubles per pood. A further organization has just been formed—Siberian Exploration Syndicate, Ltd., with a capital of £3,000—by the same group of financiers. A second group is concerned in Siberian Proprietary Mines, Ltd., floated in August, 1903, its first bantling being Orsk Goldfields, noticed in my correspondence of April 18, respecting which the latest news is to the effect that the cost of the new work, so far, has been covered by the profits resulting from the operations of the tributers, leaving the working capital of the company practically intact, the ore won on tribute from nine different veins having yielded, since the property was taken over, an average of about 55s. per ton.

The newest effort of this financial group is the issue of the Troitzk Goldfields, Ltd., with the nominal capital of £600,000 in £1 shares, 500,000 of which credited with 14s. paid up on each share, having been issued to the Siberian Proprietary Mines, Ltd., the vendors, in payment for options acquired over the properties. These 500,000 shares, now paid up in full, will provide £150,000 for the purchase of the property and for working capital, while the remaining 100,000 shares are held in reserve to provide for further exploration and plant. As to the situation of the properties, although on the main Siberian railway, the Preobragensk and Alexandrovsk gold mines are in the northwestern part of the Kotchkar goldfield, in the Orenburg province of southeastern European Russia, 64 miles south of the town of Tcheliabinsk and 49 miles southeast of Bishkil, and consequently in a less isolated position than some of the other mines working in Russia. The Preobragensk mine has been worked by its present owners for about 4½ years, and the Alexandrovsk by its present owners for 25 years. The combined area is about two square miles, the property being held on perpetual lease from the Government. According to a statement by the owners of the Preobragensk mine, it has produced 8,000 oz. gold per annum, and the Alexandrovsk mine has produced an average of 5,000 oz. per annum, making together a gross revenue of about £45,000 per annum, with only a very imperfect system of working in vogue. The present profits are said to be about £25,000 per annum from the two mines. The intention of the company is now to undertake the development and exploitation of the numerous valuable lodes already being worked, simultaneously with a more systematic prospecting of the whole property, and eventually to erect from 150 to 200 stamps to crush about 225,000 tons per annum, it being estimated that the average yield of gold will be about 30s. per ton. As to working costs, John Taylor & Sons, who have reported on the property, estimate that they will amount to about 16s. per ton, but the promoters believe that they will not exceed 12s. per ton, and upon this basis the profit per ton would be about 18s., or £202,500 per annum. The whole of the cash capital has been found by the promoters and their friends, from whom the public are expected later on to purchase the shares at a good premium by "coming in" on the market. Meanwhile it may be observed that although Messrs. John Taylor & Sons have visited the properties in question and reported on the working costs, no statement has been published as emanating from that firm respecting the probable profits. The directors are men of social prominence.

Another financial group has also secured the co-operation of men of high degree in the formation of the Siberian Mines, Ltd. The capital of the latter is £100,000 in £1 shares, of which 7,000 will be issued as fully paid, in part payment for various groups of mines to be acquired, and 92,993 will be allotted to the H. A. Syndicate, credited with 15s. paid, the balance of 5s. per share

representing the cash capital available when called up. The properties to be taken over are stated to be all in the province of Orenburg, and the terms of purchase are so arranged that only small monthly payments are to be made until a full report has been received from John Taylor & Sons, and then, if their report should be satisfactory, the company can work the properties at a small annual rental until it has proved them, and decided to complete the purchase. The company will not itself be so much a mining as a promoting concern. Not one of these various Siberian and allied mining properties has produced as yet any dividend to English stockholders, but the market position of some of them may be gauged from the report this morning in one of the leading financial papers (all £1 shares): "Spassky dipped to 5½, Siberian Props. were steady at 5½, Orsk at 1½, and Siberian Syndicate at 1½ prem. Siberian Mines were also firm. Troitzk Goldfields 1½ to 1¾."

Here is a realization of wealth from the other side of the world. Total quantity and value of gold raised in Australia, Tasmania, and New Zealand from the first discovery in 1851 to the end of 1905:

	Quantity. Fine oz.	Value.
Victoria	64,324,197	£273,236,500
New Zealand	15,827,423	67,230,584
West Australia	14,871,687	63,170,911
Queensland	14,601,249	62,022,130
New South Wales	12,534,566	53,235,286
Tasmania	1,204,364	5,498,101
South Australia	594,348	2,523,438
Australasia	124,047,884	£526,916,950

One is reminded of the eloquent popular preacher who extolled the design of Providence in causing the big rivers to flow near the sites of important cities. Truly Britain may thank that Power for depositing such a goodly proportion of the precious ore in a part of the earth's crust possessed by her enterprising sons.

Melbourne, Australia.

The Mt. Morgan Mine and Its Production.—Big Reserves of Copper Ore Under the Gold Gossan.—This Copper Refined in New Jersey.—New Processes at Broken Hill.—The Cattermole Process Doing Well.—Transfer of the Great Cobar Copper Mines.

Before me is the balance sheet of the Mt. Morgan Co., of Queensland, which has recently attained its majority. Its record is one of local unexampled prosperity, yet the State in which it is situated cannot be said to have profited by the discovery. A few people got wealth but the collapse of wild speculation over the shares led for a time almost to commercial disaster. Those who got in early and held their shares have done well. Beginning in 1886 with a dividend of 8d. per share, the company has paid dividends year after year until now the total amounts to £6,679,166. It thus is second only to the Broken Hill Proprietary as a dividend payer. The biggest record was in 1889 when £1,100,000 was distributed in the twelve months. In the following year £700,000 was paid and since then the amount has dwindled until for the last three years the dividends have aggregated £150,000 per annum. The lowest level of the mine is only at 750 ft. below the surface. Hitherto the company has relied entirely on gold for its dividends. Now, however, it is turning its hand to the production of copper. Extensive boring, done with the diamond-drill, has proved the extent of the copper-bearing formation; accordingly, a smelting plant has been erected which is now treating ore carrying roughly 7 dwt. gold and 2½% copper. In the year just ended, one furnace was in commission 131 days and treated 22,153 tons. A second fur-

nace was started late in May and in April converting was begun. The works are now turning out 9½ tons of blister copper per diem, averaging 98.6% copper and 14½ oz. gold per ton. In all probability a couple more furnaces and additional converter plant will be provided. The magnitude of the property can be realized from the fact that the estimates of auriferous copper ore—apart from the gold ore—is 1,212,000 tons, averaging 3½% copper and 8 dwt. gold; 1,597,000 tons worth 3% copper, 2½ dwt. gold; and large unestimated quantities containing from 2 to 3% copper and from 1 to 2 dwt. gold per ton. The Mt. Lyell ore works out at 2.32% copper and a fraction of the above gold contents. The estimate of cost of 35s. per ton for mining, smelting, and realization, is not being exceeded, so it will be seen what a magnificent asset the company has in its copper-gold ore. The company's output of blister copper has been sold for a term to the De Lamar Copper Refining Co., of New Jersey. During the year the company handled 288,353 tons of ore, and 344,162 tons waste. The oxidized gold ore totalled 135,210 tons, averaging 7.82 dwt. and the sulphide gold ore 104,572 tons averaging 10.82 dwt. The fine gold produced during the year was 114,521 oz. Costs at the gold reduction works were 10s. 9d. per ton.

Broken Hill is continuing its experimental work. There are three processes in the field; first, the sulphuric acid process and its rival, the Delprat process; next, the Cattermole process, and, third, the ordinary gravitation process. I have dealt on a previous occasion with the sulphuric acid processes. The Cattermole is a granulation process, and is being tested at the Central mill of the British Sulphide Corporation. The latest figures supplied by the general manager (C. F. Courtney) show that a recovery of 46% zinc has been achieved from the zinc residues and that costs are most satisfactory. This is the best grade zinc concentrate being produced on the Barrier. The company will soon supply zinc concentrate to the Central Zinc Co., England, an off-shoot of the Sulphide Corporation, which has already commenced the erection of works in England. Meantime another furnace will be installed in connection with the company's own spelter plant at Cockle Creek, making three; and possibly a fourth will be put in later. This plant would then, in Mr. Courtney's opinion, be capable of supplying Australia's demand for spelter, which is, as yet, limited. The Sulphide Corporation, he adds, has no intention of giving up the manufacture of spelter, but intends to increase the supply. The spelter process in use at Cockle Creek, near Newcastle (New South Wales), is the Sulman-Picard. The third process is the De Bavay, which is a flotation method dependent entirely on the floatability of particles of zinc sulphide on water and their subsequent collection by gravitation. It will thus be seen that the experiments in respect to Broken Hill zinc sulphides are not only of the utmost importance from a commercial standpoint, but they have high scientific interest.

The final payment has been made in connection with the purchase of the Great Cobar mines, New South Wales. The sum paid for the property was £800,000, and a deposit of £25,000 was paid at the time the option was secured. A check for £775,000 has now been handed to Dr. Read from the Great Cobar, Ltd., of London, which has bought the property of the Great Cobar Copper Syndicate. The properties acquired were the Great Cobar copper mine, the Cobar Chesney copper mine, the Peak and Conqueror gold mines, coal mines at Lithgow, coke works at Rix's Creek, smelters at Cobar, and the copper refinery at Lithgow. J. D. Kendall, representative of the English company, has arrived to take delivery of the properties.

Butte, Montana.

New Company is Organized.—Big Vein Cut by the East Butte.—North Butte Acquires More Territory.—Furnace Creek Operations.—Boston & Montana to Increase Output.—Little Mina to Resume Work.

The Colusa-Leonard Extension Copper Co. has been organized at Butte and incorporated under the laws of Arizona with a capitalization of \$5,000,000, divided into 1,000,000 shares of \$5 each. The new company owns five patented mining claims on the east side of the Butte district, about 2,000 ft. east of the Minnie Healey, Colusa, and Leonard mines, the northern portion of the Pittsburgh & Montana Co.'s ground lying between. The officers of the company are: O. B. Whitford, president; Meyer Genzberger, vice-president; James A. Talbott, treasurer; Arthur Smith, secretary. The ground is undeveloped, but is considered to be well located in view of its proximity to the big mines of the Boston & Montana Coalition. It is expected that machinery will be on the ground and sinking begun in 30 days.

The Amazon-Butte Copper Co., with a capital stock of \$2,500,000, divided into 500,000 shares of \$5 each, has been organized and incorporated at Butte, the subscribers being ex-State Treasurer A. H. Barret, George H. Casey, ex-Mayor Patrick Mullins, James H. Lynch, Christian Jacky, General Charles S. Warren, W. F. Cobban, Frank W. Haskins, William F. Love, and Charles Mattison. The company has acquired the Amazon, West Altona, and Gaynor quartz claims, all old patented properties and good prospects; these comprise about 40 acres of ground south and east of the mines of the Pittsburgh & Montana Co., and west of the mines of the Ida-Montana Co., in which latter property a large body of gray copper and copper glance has recently been opened at 100 ft. from the surface. This vein extends through the West Altona and Gaynor, while the large north and south vein of the Bullwhacker extends directly through both the Amazon and West Altona. There was considerable work done on all these claims in past years and good copper ore opened in numerous places along the outcrops. Rich float is found all over the surface, and in the early days several shipments of rich oxidized ore were made at a profit to Corinne, Utah, by team, a haul of several hundred miles. On the Amazon there is a double-compartment shaft 200 ft. deep and in good condition. Machinery is to be placed on this claim and the shaft sunk to 800 or 1,000 ft. as rapidly as possible.

The North Butte Mining Co. has recently purchased two additional mining claims, the Emily and Millview, and acquired all outstanding interests in the Gem and Snowball. The Millview and Emily lie between the Badger State of the Boston & Montana Co. and the Poser and Elm Orlu, owned by W. A. Clark. The Snowball is a narrow fraction adjoining the Berlin of the North Butte and its acquisition completes the ownership of a solid block of claims of about 15 in number.

The East Butte Copper Mining Co. has cut through the vein encountered in the southern cross-cut from the 400-ft. level of the Dutton mine, and the vein is more than 12 ft. wide. Apparently two of the veins worked on the 200-ft. level united below that point and formed the 12-ft. vein on the 400-ft. level. Four feet of the vein carries high-grade copper and the remaining eight feet is good concentrating ore. Work on the cross-cut toward No. 12 shaft, which is being sunk at the southern extremity of the company's ground, is advancing rapidly. Fully a dozen other veins will be opened by this cross-cut. Shaft No. 1 has reached a depth of 530 ft. and No. 12 is down 250 ft. After the company began enlarging and sinking No. 1 shaft, work on the upper levels was stopped. Min-

ing has, however, been resumed on the 200 level and some ore is being hoisted. Large bins are being built on the railroad track and they will be connected by an elevated tramway from No. 1 shaft.

The Lewisohn General Development Co. has purchased a half interest in the Montgomery claim, an east side property, on which a shaft is being sunk to cut the vein recently opened in the Bullwhacker claim, north of the Montgomery.

Donald Gillies, representing the Schwab and Kuntz interests in Nevada and the Furnace Creek district of California, has been in Butte the past week to consult with the directors of the Furnace Creek Extension Copper Co. relative to the proposed merger of all of the big Furnace Creek and Greenwater companies. According to reports from Greenwater the Extension Company has the best showing in that district, and the promoters of the merger are anxious to reach an agreement before proceeding with the negotiations for further territory. John MacGinniss, vice-president of the United Copper Co., and A. J. Campbell, counsel for the Amalgamated Copper Co., are the leading spirits in the Furnace Creek Extension Co. It is understood that the Extension people are willing to go into the merger, it being only a question of terms. The consolidation is to take place in the Furnace Creek Copper Co., Furnace Creek Extension Copper Co., Greenwater & Death Valley Copper Co., and several smaller concerns. The capitalization of the Consolidated Co. will be large, as the property of the Furnace Creek Copper Co. is to go in for \$10,000,000, and that of the Extension Co. will be entered for not much less.

Some remarkably good news is being received from the mines of the Butte & Arizona Copper Co., situated about 30 miles from Bisbee. An official report is that the vein of copper cut in the tunnel a week ago, and then reported to be eight feet wide, has widened to 40 ft. No assays accompanied the latest report, but last week the average value given was 7% copper. If the same average still holds in the larger orebody, the company has a remarkably rich find. The principal stockholders of the Butte & Arizona are Butte and Michigan men.—The Butte-Milwaukee Co. has cut another vein in the Pollock mine by an opening from the 250-ft. station. It is the second vein tapped and another is known to exist in the same claim. The extent of the new claim has not yet been determined. The Pollock is north of the Elm Orlu, which W. A. Clark is developing, and both are in the heart of the North Butte district. The Butte-Milwaukee Co. owns the Pollock and has options on several other properties adjoining that mine.

The Butte & Bacorn Copper Mining Co. has secured two additional and promising mining claims in the Allie Bell and St. Andrew, for which it has contracted to pay \$29,000, having taken an option that will run to January 28, 1908. The two claims are owned by Maurice Isenberg, of New York, and James W. Murphy and Duncan McRea, of Butte, and adjoin the Colleen Bawn on the north and east. The Colleen Bawn is one of the principal properties of the Butte & Bacorn, and upon which it is sinking one of its three shafts. If the Butte & Bacorn strikes copper in the Colleen Bawn, as anticipated, the acquisition of the two additional claims will prove valuable, although the Butte & Bacorn already owns more than 300 acres of mineral ground in that locality. The Parrot Co. is equipping the Little Mina mine with new machinery with the intention of resuming work. This mine adjoins the Nipper. The famous Blue vein of the Nipper, over which there was so much litigation, strikes through the Little Mina, and it is expected that with sufficient development the property can be made a good copper producer. There is a shaft 800 ft. deep on the property, and it is the intention

of the Parrot Co. to add at least 200 ft. to it, which depth, it is believed, will take it into the orebodies.

The directors of the Boston & Montana Co. have made appropriations for extensive improvements at Butte whereby the company will be able to increase its output of copper by at least 20,000,000 lb. per year. Its present output is 100,000,000 lb. The company is producing copper at a cost of 9 cents per pound, and the increasing output contemplated will give it an additional earning capacity of approximately \$2,200,000 per year. The capacity of the smelter at Great Falls will be increased about 1,000 tons per day; work on the improvements and changes at that plant are now under way.

Houghton, Michigan.

Greatly Increased Production From the Lake Superior Copper Mines. — Estimates of Future Output. — Important Statistical Data.

The great progress accomplished in the past decade, and now being carried forward at an increased pace, by the Lake Superior copper industry, is shown by the forces

copper last year, and will make nearly 50,000,000 lb. this year. In 1898 a considerable amount of new work was started, and there was a revival of the copper mining industry in both Keweenaw and Ontonagon counties, while 1899 was signalized by a mining boom of proportions unprecedented in the history of the district. Great as was the activity of 1898, there is more new work under way in 1906; but the work of the present day attracts far less attention and comment than seven years ago, due to the growth of the mining industry. In place of the 20 miles of copper belt on which seven mines were working ten years ago, there now are nearly 20 producing mines, and an equal number of developing properties, some of which are working on a large scale.

Although the Calumet & Hecla remains the leader, it is no longer the producer of more than half of the copper made by the Lake district, as was the case from 1870, only four years after the mine was opened, until and including 1901, with the single exception of 1892. For 1905 the Calumet & Hecla made but 41 % of the copper turned out by Lake mines. In 1895 the Calumet & Hecla

Each rectangle is a township, six miles square.

The Copper Region of Lake Superior.

employed and by the capital invested in the business, as well as by the steadily increasing output of copper. In 1905 the production of refined copper by the Lake Superior mines was 129,198,460 lb., and in 1905 the output was 229,270,035 lb., showing an increase of 77 %. In 1905 the forces employed in the copper mines of the Lake district were 7,249 men, while at present the force is about 18,000 men, for the mines, mills, and smelters—an increase of 148 %. It will be noted that the increase in forces is almost double the increase in production, the reason of which is not that the men are less efficient now than ten years ago, it is due rather to the vast amount of new work now under way.

Ten years ago the Lake Superior industry was at its lowest ebb. There were only seven mines in operation, and work was in progress along but twenty miles of the mineral range, in Houghton county, all work having been suspended in both Keweenaw and Ontonagon counties. Exploratory work was practically unknown during 1894, 1895, and 1896, and the producing mines did practically no dead work, with the single exception of the Calumet & Hecla, which continued its time-honored policy of opening ground for ten years ahead of immediate requirements. In 1897 there came a change for the better, with the beginning of exploratory work at Six-Mile mill, south of Houghton, and from this new beginning have grown the Baltic, Trimountain, and Champion mines, which made more than 40,000,000 lb.

made 79,137,399 lb. fine copper out of a total production of 129,198,460 lb., leaving only 50,061,061 lb. from other mines, while in 1905 the Calumet & Hecla made 95,100,610 lb., an increase of 20 % in 10 years, and other mines made 134,159,425 lb., an increase of 168 per cent.

The vast amount of exploratory and development work now under way, both at the old mines and at the properties not yet productive, will require years to arrive at full fruition. From five to seven years' time and the expenditure of one and a half to two million dollars are required to make a new mine in this district, and the production of 1905 may be said to mark the results of the work begun in 1898 and 1899. Predictions are hazardous, but in a general way it is possible to forecast the results six years hence. Long before that time the Calumet & Hecla should have a monthly productive capacity of ten million pounds of fine copper from the shafts of its main property, in addition to which the company should be getting an output, by that time, from several of its numerous subsidiary properties, of which three, the Manitou, Gratiot, and Superior, make a promising showing. From its main tract the Calumet & Hecla should make approximately 125,000,000 lb. in 1912. The Baltic, Trimountain, and Champion mines of the Copper Range Co. should yield at least 75,000,000 lb. in 1912, leaving out of account the Globe, which promises well. The Osceola should be capable of producing 25,000,000 lb. six years hence. The five mines enumerated in the forego-

ing list should make, by the figures given, 225,000,000 lb. copper in 1912, practically equivalent to the total output of the 18 producing mines of the district during 1905, leaving the output of 13 other producing mines of 1905, plus the output of new mines as a net gain for the output of the district. In all likelihood the 1912 production of the Lake Superior mines will reach 375,000,000 lb. of copper.

Leadville, Colorado.

Good Output Last Month.—Many New Developments and Discoveries. — Sugar Loaf District Reviving. — Important Find in Iowa Gulch.

Despite the fact that during the early part of the month the smelters were compelled to face a serious condition because of the scarcity of labor, and that a number of the mines took advantage of the situation to close down for needed repairs, the output of the district for September reached the sum of 89,230 tons, as compared with 88,600 tons for August.

The Penrose has completed the installation of its underground electric plant, which is being used to furnish light for the mine. A Pelton wheel, driven by water from the Bison workings, furnishes the power. A shaft is being sunk on the Holy Cross vein of the mine. The vein carries good ore and at present writing over 1,000 tons of ore is broken and ready for shipment and milling. —The Aetna Mining Co. is sinking a shaft on its property on Carbonate hill. At a depth of 300 ft. the shaft is still in lime, but it is expected in the next 50 ft. to reach the parting quartzite, the horizon at which many of the adjoining properties produced their rich chloride ore. —The Yak Tunnel lateral has reached the Louisville workings and completely drained the property. Development work will commence at once on the lower levels, where large bodies of iron-zinc sulphides were lately exposed. —The installation of a plant of machinery on the Jennie June has been completed and the manager reports a good body of ore exposed in the workings ready for stoping.

A new company, called the Bonanza Mining Co., has entered the Alma district and secured approximately 50 acres of mineral ground. A force of men will be put to work developing the property as soon as arrangements are completed. —The New Era will install a new plant of machinery during the month. —For some time past a force of men has been employed by the R. A. M. Co., repairing the shaft and surface buildings. It is the intention of the management to put a force of men into the mine as soon as the surface improvements are completed. This property was formerly a large producer. —The Country Boy, on Nigger hill, is proving a bonanza to the Lanyon Zinc Co., of Iola, Kansas. From this property during a single month 450 tons of zinc ore running above 40% zinc have been shipped, in addition to the milling ore. The company is pushing development work.

An important strike is reported on the Lord Byron property in Iowa gulch. At 30 ft. depth a good body of ore carrying 7% lead, 16 oz. silver, and 27% zinc has been encountered. This discovery will stimulate development work on many properties in this locality. —Another district to come to the front is Sugar Loaf. At present 130 to 150 tons are being shipped daily and the old Dinero, which produced heavily in former years, is soon to be among the active properties, as the Dinero Consolidated Mining & Milling Co. has been organized to re-open the workings. This mine has two fissure veins which formerly produced quantities of high-grade ore. A superabundance of water stopped operations at the lower levels and forced the work to the upper workings, where low-grade ore was mined. An adit will be driven 3,000

ft. from the base of the mountain to a point below the Dinero shaft; this will not only remove the water but will furnish a means of easy transportation of the ore to the smelter. Among the improvements, an electric plant will be installed for light and power.

Morenci, Arizona.

Activity at the Silver Bell and Imperial Mines.—Important Development in the Humboldt Mine.—The Arizona Copper Co. makes Many Improvements.

Much activity is being shown at present at the Silver Bell mine. The big air-compressor will soon be ready for work, and the erection of the smelter will also be commenced. The Imperial Copper Co. is sinking its shaft to the 900-ft. level, and when the compressor is ready to operate air-drills, the shaft will be continued to the depth of 1,800 ft. It is estimated that the smelter will be completed in about six months, and besides treating the output of its own mines the Imperial Copper Co. will do custom smelting.

The Cleveland-Arizona mine, said to be under the control of the Standard Oil interests, having been flooded, the management is now installing machinery to get rid of the water. The main shaft is now down 600 ft., with 600 ft. of lateral work. A large number of other claims are also being worked here by this company. Sinking is being continued on the Arcade group of 16 claims, where there is a good showing. The Indiana-Arizona main shaft is down to 400 ft. and has uncovered high-grade copper ore. The Great Sulphide Copper Co. is sinking its shaft below the 300-ft. level and will prospect thoroughly with a diamond-drill. Development work is going steadily ahead on the Crepin-Richardson group, and the showing made is considered highly satisfactory. The main shaft of the Cole-Clidden mine is down over 200 ft. and good copper ore has been encountered. The La Mina Cobre Co., which is working twenty claims, is sinking a timbered, double-compartment shaft to a depth of 115 ft., where lateral exploration will commence. Two gold claims owned by Dick Lakenan in Gold gulch have been leased to Walter Doudna.

At the Humboldt mine, of the Arizona Copper Co., an important vein has been discovered 420 ft. from the shaft on the first level. Some ore had been taken from the vein previously, but it gave out after driving a short distance. A drift going north was begun lately and the face of it was advanced 135 ft. from the main level. The vein was small for the first 100 ft., but then began to improve. On the 60-ft. level in No. 12 drift, a good vein of ore was found between stopes No. 12 and 13, and a raise put up from the adit-level to connect. On the third level of the King group, beneath stope No. 3, an incline winze has been sunk 70 ft. in good oxidized ore, finally meeting sulphide ore, which assays 14% and is eight feet wide. On the fourth level the old King vein has been exposed 450 ft. below the first level; this constitutes the most important development in this ground for the past six months. Where it was cut the vein was of sulphide ore, 18½ ft. thick, and assaying 5.1%. It has been followed for 150 ft., and so far it maintains its value. By this exposure a very large body of sulphide ore has been placed in sight between this and the upper level, a distance of 237 ft. Raising for air and further driving are in progress. At the claims of the Arizona Copper Co. above Metcalf many surface improvements have been in progress during the past six months so as to allow of handling a larger tonnage. A 125-h.p. boiler has been erected preparatory to replacing the gasoline hoist by a double-drum steam-hoist. To supply water to the mine and camp, a well was sunk in Chase creek, half a mile north of Metcalf. Here a suction and a force pump have been installed, and

water is elevated through a 2-in. pipe-line 2½ miles long to tanks of 60,000-gal. capacity situated above the mines. The tramway to the head of the incline is being improved to allow a light locomotive to replace the present horse-haulage. The installation of the steam hoist, steam haulage and other improvements will result in a much larger output for this group.

Toronto, Canada.

Cobalt is Booming.—The Foster-Cobalt Deal.—Wonderful Showing of Silver in the Nipissing.—Encouraging Development in La Rose Mine.—Other Finds in the District.—Doubt Thrown on Peace River Discoveries.

Cobalt is booming as it has never boomed before as a field for extensive investments. The sale of a controlling interest in the Foster-Cobalt mine to a syndicate composed partly of American and partly of Canadian capitalists is regarded merely as a prelude to the consummation of many similar deals now in contemplation, by which paying propositions which have only been worked in a small way will be acquired by men with ample cap-

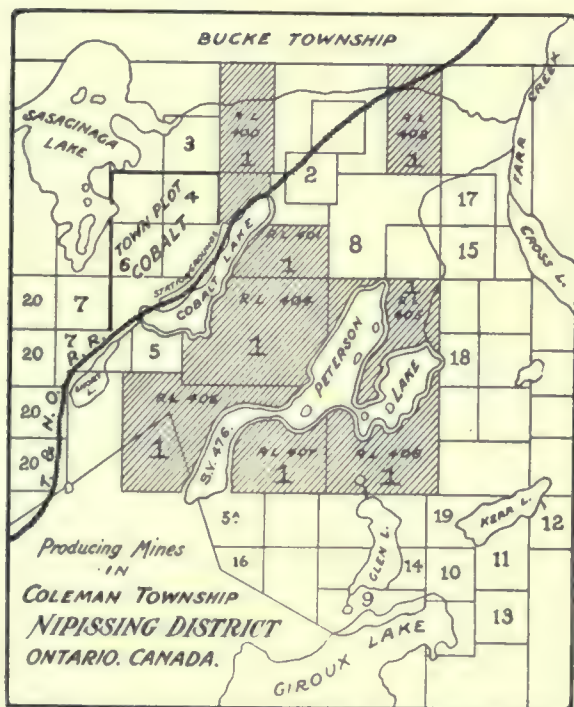

hoists installed. Yesterday 35 tons of ore, valued at from \$60,000 to \$70,000, were shipped from the mine. F. C. Loring, the mining engineer in charge, says that ore of the value of \$700,000 is already blocked out. The exact details of the deal under which the syndicate secured control are not known, but it is understood that 600,000 shares were bought at about \$1.50 per share, the par value being \$1.

At the Nipissing, the now famous vein known as Ledge 49, is being opened up under the superintendence of Capt. John R. De Lamar and Ambrose Monell, two of the directors. Large crowds have been attracted by the great nugget extracted from this vein, weighing over two tons, the silver content of which is estimated at \$19,000. The vein has now been uncovered for about 260 ft. For 150 ft. of this distance, according to Prof. W. E. Hidden, it has a width of about 60 in., then narrowing down to from 14 to 28 in. The contents of the widest portion of the vein are largely cobalt and other inferior ores, but as the vein narrows it increases in richness, the silver content being about 50%. The persistence of this vein in width and richness for a depth of 50 ft. below the surface would indicate a value of about \$4,000,000. As other veins in the neighborhood have been worked to that depth, and in some cases below it, without showing any falling off, this is regarded as a safe estimate. Prof. Hidden states that the company will erect a building 150 ft. long, covering the most valuable portion of the vein, under which the work will be carried on. In some spots the vein will have to be chiseled out, owing to its richness in pure silver. A large central compressor-plant will shortly be installed for the supply of power to the various workings, and a central shaft is being sunk at Ledge 49, which will be continued to a depth of 500 ft. At Ledge 26, the output of silver from which has been over \$300,000 to date, a shaft is being sunk and operations will be continued all winter. At the 70-ft. level of this shaft, drifts will be run into the three veins which converge near this point. The hydraulic plant used for the work of stripping and disclosing new veins has proved the economy of the process and fully justified the experiment, some half dozen veins having been discovered by this means. Ore shipments from the Nipissing mines to date have aggregated about \$1,400,000.

An important feature in the development of La Rose mine is the recovery of one of the veins which at a depth of 225 ft. went into the walls and disappeared altogether at 300 ft. Cross-cutting, however, showed that the vein was still there. The fact is regarded as auspicious for the future of the camp. Three carloads of ore were shipped from La Rose last week.—The Buffalo mine has three carloads of ore ready for shipment, one carload being high grade.

Among new discoveries reported and awaiting official inspection are a find of gold-bearing quartz by Gordon Benson about two miles southwest of Cobalt town, and a silver-cobalt vein 18 in. wide just north of the Red Rock property in Bucke township.—The Right of Way Co., which recently acquired the mining privileges on the right of way of the Temiskaming & Northern Ontario Railway, held a meeting for the organization at Ottawa recently, T. A. Beament being elected president, E. Seybold, vice-president, and E. A. Larmonth, secretary and treasurer. Work has just been commenced on the property.

The Dominion Geological Survey officials are disposed to doubt the value of the reported discoveries of gold by J. A. Macdonell, in the Peace River district of Alberta. They state that last winter some of the samples were examined by them and found to be iron pyrite. Mr. Macdonell is positive that the gold is there, stating that

ital to introduce modern machinery and exploit them thoroughly. The past week has been characterized by the visits of many capitalists to the camp and important developments in the transfer of properties to be largely capitalized and put on the market are daily looked for. The success of the Nipissing flotation combined with the practical results which have followed the application of improved mining and prospecting methods, marks the inauguration of a new era of production on a large scale and the gradual disappearance of the small operator.

It is understood that Toronto and Montreal capital is largely represented in the Foster-Cobalt syndicate, and that the president of the reorganized company will be W. K. George, of Toronto. A new manager, A. W. Scott, a former Nevada miner, has taken charge and introduced many changes. The staff of 40 men employed will be largely increased and compressor-plant and steam-

he tested it with quicksilver. Thorough tests will be made here and at Montreal.

A new mining division has been created comprising the territorial districts of Parry Sound and Muskoka, to be known as the Parry Sound mining division. Henry F. McGuire is appointed recorder.—Charles W. Belyea has been appointed recorder of the Kenora mining division.—The Canada Corundum Co., Ltd., has been authorized to increase its capital stock from \$1,500,000 to \$2,500,000.

Another big strike has been made at the Laurentian gold mine, in the Manitou Lake area. The raise from the first level is 50 ft. up, with rich ore all the way. While driving operations were in progress to connect the top of the raise with the main shaft, unexpected resistance was met with from massive gold which the machine-drills were unable to penetrate. Blasting was resorted to, one shot bringing down \$15,000 worth of gold. The ore at this point is three-fourths native gold.

Cripple Creek, Colorado.

Output to Increase Shortly.—Rich Strike in Lucky Gus.—New Machinery for the Jerry Johnson.—Treatment Charges.—South Dante in Big Ore.—Portland Cyanide Plant Nearing Completion.—Heavy Output From the Granite.

The output of the camp for the month of September was considerably less than that of previous months, which was due, to a great extent, to several mines storing a part of their production to be shipped at a later date to mills (outside of the trust) now in course of erection. The September tonnage of the district treated by the United States Reduction & Refining Co. fell off about 5,000 tons. When the Golden Cycle mill at Colorado City is completed, which at the present time does not seem probable until the early part of December, the tonnage of the district will increase quite materially. The enlargement of this mill to accommodate an increased capacity of 400 tons is already discussed by the management.—A rich strike of ore at a depth of 300 ft. has been made during the last few days on the Lucky Gus of the Stratton Estate, situated on the southwest slope of Bull hill. A carload from this new find, which is being broken three feet wide, went out the first of this month and is expected to run \$75 per ton.—Another 100-ft. lift is to be sunk on the Gold Sovereign shaft on Bull hill to enable the large orebody recently discovered on the 800-ft. level to be economically worked. The ore from this mine will be shipped direct to the Golden Cycle mill at Colorado City in the near future.

New machinery, to replace that destroyed by fire on the Jerry Johnson mine recently, has been ordered and will shortly be on the ground. The 600-ft. shaft will be sunk to facilitate thorough development of the property.—A circular letter has been sent out by the Findley Gold Mining Co., stating that shipments will be discontinued to the plants of the smelter trust owing to the excessive rates of freight and treatment. No ore will be shipped until the Golden Cycle mill is ready to receive it. The difference between the open rate of the smelters and the rate at this mill is approximately \$3 per ton, which on an output of 200 tons or more per month makes a big difference in the profit. The Golden Cycle Co. is now in the market for ore to be treated in their mill at Colorado City.—Two leases have already been granted on the United Gold Mines property. Frank Edwards, of Independence, has obtained a lease on the Trail claim below the tunnel level. The term of the lease is for one year and the royalties are graded from 15 to 30%. Fifty shifts of work per month are required by the lessor company. The northern part of the W. P. H. claim, situated

on Ironclad hill, has been leased to Morris Eads, of Victor.—The lease of the British American Mining Co., Ltd., on the South Dante, has become one of the most promising in the district. Operations are being carried on at a distance of 3,000 ft. from the mouth of the Trail tunnel in Eclipse gulch. This long tram greatly retards the output, but the adit is now being straightened and put into shape to handle the increased tonnage. Ore is being stoped from a junction of veins, everything being shipped just as it is broken. Assays taken across the orebody, which is between 20 and 30 ft. wide, run from \$15 to \$300 per ton, and rusty gold can be seen in many places.

The Portland Gold Mining Co. has declared its regular quarterly dividend of five cents per share, amounting to \$150,000. The cyanide plant being built by this company at Colorado City is nearing completion and will treat the immense tailing dump from the mill. The output for the month of September from the Granite mine on Battle mountain was approximately 2,250 tons on company account and 600 tons by lessees operating on the Monument, Gold Coin, and Upper Granite claims. The grade of the ore averaged an ounce and a half per ton. This heavy production makes the Granite property one of the foremost in the district.—Owing to the recent snow-storm, which has made the roads heavy, the Little Clara mine has not been able to ship its ore fast enough to keep the ore-house clear. Marsh, Hodges & Co., leasing on this mine, are very anxious to force the production, as their lease expires in a year and they do not care to take any chances in case of renewal being refused.

Salt Lake, Utah.

Local Business.—Activity in Beaver County.—Gold Springs Camp.—Daly-West Makes a Strike.—News From Tintic.—Increase of Gold in the Ohio at Bingham.

The ore and bullion settlements of the past week amounted to \$705,000 and the sales of the Salt Lake Stock & Mining Exchange during the same period aggregated 317,043 shares, for which \$178,844 was paid.

Beaver county is the scene of increased activity and important developments have been reported from a number of mines there. In the Cactus, operated by the Newhouse Mines & Smelters corporation, a large orebody, heretofore unexplored, has been opened on the lower levels. It has been cross-cut on the 600 level showing a width of 68 ft., the mass being mill-stuff mixed with a great deal of high-grade shipping ore. The new find has caused a marked advance in the price of the stock.—The Cedar Mining Co., operating near Milford, in a cross-cut from the 125-ft. level of an incline-shaft has cut a body of high-grade silver-lead ore. The company is preparing to make shipments. Herman Barnett, of Salt Lake, is manager.—The Revenue Mining Co., of which L. G. Burton of Salt Lake is consulting engineer, has been carrying forward a vigorous campaign of development for several years and has acquired patents to about 2,000 acres. A large tonnage of ore has been developed and a new stamp-mill, which is to treat from 25 to 50 tons of ore daily, is nearing completion.—Unusual activity is being displayed all over the western part of Beaver county and good results are being obtained almost everywhere.—In Iron county, too, mining is picking up. The new camp of Gold Springs is rapidly coming to the front. A representative of the Davis-Daly Estates has acquired short-time options on a number of properties there, among them being the Donohue group. The Jennie Gold Mining Co. is developing ore rapidly and will soon begin shipping. The General Engineering Co. of Salt Lake is making some tests of the ore and

drawing plans for the proposed mill, which will start with an initial unit of about 30 tons of ore per day. The Jennie shaft is situated about 15 ft. from the Utah-Nevada State line and the company owns ground in both Utah and Nevada. Charles A. Short, of Gold Springs, is manager of this company.

The Little Bell contact vein, which the management of the Daly-West Mining Co. has been driving for during the past few months, has been encountered and is considered to be the most important development in that mine in a number of years. A drift 40 ft. long on the vein has been run in four feet of high-grade ore. The Western Utah Copper Co. has filed articles of incorporation in Nevada to operate the Gold Hill mine in the Clifton section of the Deep Creek mining district. The company is controlled by parties heavily interested in the Bingham Con. M. & S. Co., and is capitalized for 500,000 shares of \$5 each. The officers and incorporators are: W. S. McCornick, presi-

Utah.

dent; Duncan McVichie, vice-president; H. H. Green, secretary and treasurer, who, with E. L. White, F. Augustus Heinze, Henry N. Sweet and John A. Street are directors. Some extensive bodies of copper ore have been developed. The mine is situated 30 miles from the main track of the Western Pacific railroad and will be reached by a branch line. The management of the Eagle & Blue Bell mine in the Tintic district reports the strike of a large body of good ore at a point 400 ft. north of the shaft on the 1,000-ft. level.—The Annandale property in the Tintic district, optioned to F. Augustus Heinze, several months ago, is being developed. The ground adjoins the Centennial Eureka mine, which is under the control of the United States Smelting, Refining & Mining Co.—The management of the Lower Mammoth Mining Co., in the same district, has ceased work on the 1,700 level pending the sinking of the main shaft from the 1,500-ft. level.

Ground has been broken for the three-compartment shaft to be put down on the property of the Ohio Copper Co., at Bingham, while development and extraction goes on steadily in other portions of the mine. The shipments of concentrate during the past week has revealed the presence of larger gold values than heretofore obtained in this property, control assays showing as much as \$3.20, as against 70 and 80 cents in former shipments, while the copper ran about 24%. The Ohio looks now as if it would make one of the big shipping mines of Bingham.

Mining Summary.

ALASKA.

Gold to the value of \$50,000 has already been brought from the new placer diggings in the Yentna district, lying south of Mount McKinley in Alaska. The pay has all been extracted from stream diggings, the benches having received but little attention. The locality will probably be thoroughly prospected in the immediate future, as it is comparatively easy of access from Seward.

ARIZONA.

COCHISE COUNTY.

At Johnson Camp, Brown & Wien have taken a bond and lease on four claims belonging to Ben. X. Williams. The bond is for one year at \$25,000, and the lease calls for a 10% royalty. They have some good copper ore in sight.—Elex. Bannow is doing assessment work on his group of copper claims.—W. A. Johnston has let a contract for development work to be performed on his group of four claims.—Machine-drills have arrived and are to be installed in the shaft of the Arizona & Michigan Co.—Supt. Mackay, of the Black Prince Co., is preparing to install machine-drills.—There are three sets of lessees operating on the Mayflower copper claim, and all are getting good results.—The Republic continues to make regular shipments of ore.—The Peabody holds her record as a good producer, shipping about three cars per week.—The People's Party group is being worked by the new owners and bids fair to rival the Peabody.—The Cochise Copper Co. has its shaft down 230 ft. into the wash; three shifts are at work. George M. Brown, the superintendent, expects to encounter the lode at about 250 ft.—This camp has produced within the last six years approximately one million dollars worth of copper, one-half of which is profit. While the Peabody has furnished about half of this amount, the Republic, Mammoth, Copper Chief, People's Party, and other groups, have contributed also. Although several of these mines have been worked for more than 25 years, comparatively little development work has really been done. It is only within the last year that capital has become favorably impressed with the district, and while there is much activity, there is still a wide field of undeveloped prospects which offer fair inducements to speculators. There being little or no positive ore blocked out, the properties cannot as yet be offered as investments.

YAVAPAI COUNTY.

(Special Correspondence).—Among a number of mining properties upon which development work has been recently inaugurated in Yavapai county, and which give promise of doing well, is the Fuller group of mines in the Squaw Creek district, recently purchased by the White Horse Mining Co. Despite the distance of the mines and district from railroad communication, these mines have from time to time produced a large amount of high-grade ore, work being later discontinued when the water-level was reached, and the ore gave indications of changing to sulphide. The new concern which lately acquired the property is under the management of the Manhattan Securities Co., of New York, with T. E. Campbell as general manager, who is conducting the operations in a miner-like way with a view to getting the property in shape for economic work. The underground operations are at present confined to running No. 2 adit to connect with No. 2 shaft, a distance of 200 ft. farther west along the vein. The shaft is now 127 ft. deep, and the adit will tap the vein at a depth of 188 ft. below the bottom of it. From this shaft some of the best ore ever found in the mine was taken in 1898 by Colorado miners, who had a lease on the ground. The pay-streak in the adit is now five feet wide, and samples on the average \$12 per ton in gold. In addition to this, and associated with the pay-streak, a four-inch vein of sulphide ore was recently uncovered, which gave returns of \$130 per ton in gold, and which appears to be widening out as the adit is being advanced. Since this sulphide ore was struck there has been an increase of water, but not enough to interfere with the work. The water can be used to great advantage later,

when work on the mine is far enough advanced to commence the treatment of the ore in the mill. This is the first water of any consequence ever struck in the mine, and coming, as it does, with the appearance of the sulphide ore, is a good indication that the sulphide streak is a permanent one.

Phoenix, October 5.

CALIFORNIA.

CALAVERAS COUNTY.

The Mokelumne Hill mining district is the scene of much activity. The 20-stamp mill at the Hamby mine is nearing completion, while in the eastern part of the district, the Easy Bird mine is increasing the capacity of its reduction plant, a large rock-breaker and another concentrator being added. North of the Easy Bird is the Lucas mine, which is being equipped with a compressor and three power-drills. —The North Star mine is going to be systematically worked and the main tunnel re-timbered. —A new shaft is to be sunk on the Blue Jay mine. Over 50 men are now employed in the Mokelumne Hill district.

NEVADA COUNTY.

E. B. Whitehead has been developing a valuable claim at Deadman's Flat. Five well-defined veins have been discovered varying from eight inches to four feet wide and assaying \$10 to \$30. The ore is free-milling and of the 'blue ribbon' variety, which has proved so productive in Grass Valley.

SIERRA COUNTY.

(Special Correspondence). —The rock-house at the Sierra Buttes mine burned on the 7th inst., and will cause the tramway to close down for a short while. —The Hayes Con. Co. is rushing the building of the 20-stamp mill and will soon have it ready. —The Sovereign Co. is sinking a shaft on the Nevada claim; it is in sulphide ore, principally iron pyrite and galena, averaging \$40 per ton. —The Empire Co., in Gold Valley, is re-building the 25-stamp mill and adding a cyanide plant to treat the tailing. —J. W. Buckingham has completed his five-stamp mill and began crushing last week. —The Tightner mine has increased its force and will complete the adit as soon as possible, which will be 1,400 ft. long. H. L. Johnson is superintendent. —Tom Winrod, Ed. Deal, and H. W. Turner, owners of the Antler mine, have completed the adit and struck the vein 200 ft. in depth, which is 10 ft. wide and pans \$4 per ton in free gold. This is a promising prospect that bids fair to become a good mine. —F. P. Roddy, superintendent of the Poker Flat mine, has returned from San Francisco and is repairing the mill. —Hood & Kelleher, who have been mining on Bunker Hill for a great many years, have struck the gravel channel on the rim and it prospects well in coarse gold. —Poore & Johnson, at Deadwood, have struck gravel that pays one ounce to the set of timbers. —The Telegraph Co. has been troubled with water. It is increasing its pumping capacity and will resume sinking soon. —The South Fork Gravel mine is working with two shifts in the adit and is in the same character of bedrock as on Bald mountain. They expect soon to strike the channel. —R. D. Williams has struck a two-foot vein in the Eagle Bird mine at a depth of 200 ft.; this is a fissure vein in the granite near the head of Jim Crow canyon.

Downieville, October 8.

SISKIYOU COUNTY.

The Lanky Bob mine at Salmon river has a force of men at work, and the mill is running constantly on quartz which averages \$25 per ton. This is the mine about which considerable litigation has been in progress, with a case still on trial by appeal to the Supreme Court. —The California Associated Mining Co., which purchased the old Gold Ball or Yreka Mining & Milling Co. claim, has twelve men employed in development work to open the claims for extensive operations. The first payment on the claim was made some time ago, and the balance is expected as it becomes due under terms of the bond.

C. A. Patterson is shipping a ton sample from the Spencer claim on Humbug creek. —The Advance mill and the Highland mine in the Salmon River district are now running continuously in spite of the scarcity of water. —The Yreka dredger has been shut down indefinitely.

TUOLUMNE COUNTY.

Development work done at the mine on the Kline ranch, near Stent, since the recent strike, shows improvement in the ore as depth increases. The owners are getting from \$1 to \$10 per pan from the fine quartz after blasting. —The 10-stamp mill of the Imperial mine, near Jacksonville, is being put in readiness for operation. —Rich ore has been uncovered in the Blackhawk mine, situated west of Soulsbyville and operated by A. A. Irish, of Los Angeles. It is reported here this week that the ore will run into the hundreds of dollars per ton. The vein is three feet wide where the discovery was made. —It is rumored that negotiations are under way for the purchase of the Confidence mine. —Within a few days the 5-stamp mill of the Mary mine, the property of the Mountain Mining Co., will be started up. —Development work at the Uncle Sam mine, near Arasterville, is being done on a shoot of ore rich in free gold, recently uncovered. —The shaft of the Longfellow mine, at Big Oak Flat, is being sunk to a depth of 700 ft. Until new orebodies are opened up, the mill will run daytime only. Underground work is being prosecuted with three eight-hour shifts. —The force at the Providence mine numbers 25 men and is being increased. —It is reported that the Del Monte will soon be in operation again. —The Lady Washington mine and millsite and the California and Golden West mines, situated near Tuolumne, were conveyed by deed on the 4th inst. to W. C. Elkins, of Cleveland, by E. P. Heald, of San Francisco.

The Golden Rock ditch, which will supply water to the mines about Groveland and Big Rock Flat, is nearly finished, and the citizens of the 'south of the river' are making preparations to celebrate. —The Big Creek Gold Mining Co. has manufactured enough lumber for its proposed long flume and its sawmill has been closed down. —At the App mine, 100 men are employed. The machine and blacksmith shops and other buildings recently destroyed by fire are being re-built. A 25-drill compressor has been installed. —The Tuolumne Water Co. expects to keep nearly 200 men employed throughout the winter on the big dam being constructed and on other improvements. Next year there will doubtless be an ample supply of water for all the mines desiring it. —At the property of the Standard Gold Mining Co. the adit last week reached the Hardtack vein on the foot-wall. Considerable work has been done to accomplish this, but the discovery made is said to be regarded as ample compensation for the outlay of money and time. The ore is rich and the strike is considered valuable. T. F. McAvoy, the superintendent, has 12 men employed at this mine. —The force at the Don Pedro mine is being increased.

Tuolumne, October 8.

COLORADO.

PARK COUNTY.

(Special Correspondence). —The Snowstorm Hydraulic Co. of this place has closed down for the season. The manager, W. E. Thorne, reports a very satisfactory clean-up. During the early part of the year most of the work which was done on the placer was development work, but the latter part of the season, especially the last two months, has shown a nice profit to the company. The early snow would indicate that the coming year there will be plenty of water for hydraulic purposes. The Snowstorm intends driving a long tunnel through the banks of Beaver creek. During the last season Mr. Thorne has had drills at work prospecting the Beaver creek placers and the results of the drill-holes justify a large scheme of operations. The work will probably be carried on through the winter months, so that when spring opens up the company will be ready to proceed with hydraulicking.

Alma, October 5.

GUNNISON COUNTY.

(Special Correspondence). —J. M. McDougal, manager of the Denver City mine, 12 miles southeast of Gunnison, recently cut 6 to 8 ft. copper and zinc ore at a depth of 112 ft. The ore runs 36% zinc and 10% copper. Mr. McDougal has about 200 tons of ore in the bins and has completed 600 ft. of drifts and cross-cuts. The ore also carries \$4 in gold and silver.

Gunnison, October 2.

The Carter tunnel, of the Ashland Mining Co., is 2,400 ft. in length, and is opening up ore; later on, when development work has progressed far enough, the company will build a mill for handling this ore. At present a drift is being pushed ahead on an 18-ft. vein near the breast of the adit. There are five other veins on which milling ore has been opened up. This company owns the ground ahead of it for over one mile and after this territory has been pierced, the adit will be extended and used to transport the output of mines to the east of it. The property is equipped with a Leyner compressor and power-drills. Carrol M. Carter is president and general manager.—The Grand Prize adjoins the Ashland on the east, and is shipping five 20-ton cars per month that will average \$100 per ton. W. C. Black, of Salida, is the manager.—About one mile north of the Carter tunnel is the Raymond Consolidated Mines Co. During the past year a new mill has been built. The adit is now 2,200 ft. in length and there is about 1,000 ft. of drifts on the first vein, 500 ft. on the second and 400 ft. on the third vein. In the upper works, there is a tunnel 900 ft. long with a 200-ft. winze. These upper workings are connected with the mill by an aerial tramway, which handles eight tons of ore per hour. On the last vein cut in the main adit a raise is being made to connect with the upper workings, so that all the ore from the surface can be brought down through the lower adit instead of over the aerial tramway. The main adit is 9 by 9 ft. in the clear and it is the intention of Eugene M. Lamont, the manager, to lay a double track and either use compressed air or electric haulage. The power plant consists of two 100-h.p. Union Iron Works boilers; one 20 by 20 in. Norwalk compressor; one 20-h.p. Climax engine; one 150-h.p. Skinner engine, which operates the mill by means of a rope drive; two 250-volt generators. The ore first goes through a 10 by 16 in. Blake crusher and is then elevated 25 ft. by a belt-conveyer and discharged into the battery-bins and fed through four automatic Challenge feeders to the stamps. The mill contains four batteries of 1,000 lb. stamps making 105 drops per min. It then passes over amalgamating plates and thence to four Wilfley and four Card concentrators. The tables discharge into shaking launders which feed automatically to a dryer. The mill work is done by four men on two 12-hour shifts, and produces about 500 oz. in gold bullion per month and 150 tons of concentrate. The slime is handled by the Roberts slime table, which is said to be a satisfactory machine. The dryer is of the hoe conveyer type and reduces the moisture in the concentrate to 1%. The concentrate as sacked for shipment will average \$30 per ton. This mine is situated about five miles from the Gunnison division of the Colorado & Southern railway, from which point all supplies for the mines and mill are brought by wagon. This mill was furnished and constructed by the Colorado Iron Works Co.—The Goldsmith Leasing Co. has recently secured a lease on the old Goldsmith mine and is preparing to put in a stamp-mill which was purchased some time ago from the Morse Bros. Machinery & Supply Co. They claim to have a good streak of smelting ore which runs from \$80 to \$100 per ton. The mill-dirt runs \$17 to \$20 per ton. E. C. Statler is manager.—The Gold Link Co., of which A. E. Reynolds, of Denver, is the principal owner, has started excavating for a mill.

Ohio City, October 4.

NEVADA.

LINCOLN COUNTY.

(Special Correspondence).—The shaft of the Wyoming Searchlight is down 209 ft. From the experience of adjoining properties only about 40 ft. more work will be necessary to reach water-level.—Harry Adsit, manager of the Colorado-Nevada property and formerly manager of the Tomboy mine in Colorado, reports 185 ft. of work in his double-compartment shaft. All the work done on this property is of a substantial kind, showing the confidence of the owners.—On the Blossom, from which \$317,000 was extracted during development, work will shortly be resumed. The Pompeii also will resume; in the meantime it is affording Searchlight with a supply of excellent water, the capacity being 160,000 gal. per day.—Forty-seven men are at work on the Searchlight M. & M. Co. A cyanide

plant capable of handling 100 tons per day is almost completed; 20 vats have been installed. Two 70-h.p. boilers are being put in, the work to be entirely completed within ten days. They have 3,000 tons of tailing already accumulated, which will run over \$5 per ton. The cost of handling the tailing through the new plant is estimated at \$1.19, making a clear profit of over \$4 per ton. The shaft on this property is down 350 ft. Several new cabins are being erected for the accommodation of the increased force of men.—A. A. McKnight, of the Mines & Securities Co., Denver, has a bond on the Stoner property in El Dorado canyon. They have outfitted at Searchlight, preparatory to working a large force of men. F. Wallace White, of Pittsburg, has been visiting the Wallace group in El Dorado canyon, with the intention of acquiring property for his syndicate.—The Quartette Mining Co. is making improvements on its miners' cottages. Superintendent Harrington, who recently suffered from a stroke of apoplexy, is reported better.—The electric machinery has finally arrived and the entire Searchlight lighting system will be working within a week.—G. F. Colton, one of the owners in the Duplex, which was recently sold to John Brockman and Count Portales, is here. Mr. Colton is the man who named the town of Searchlight.

Searchlight, October 6.

NYE COUNTY.

(Special Correspondence).—Charles E. Knox (president of the Montana Tonopah), Harry Ramsey, James L. Butler, and Frank M. Ish, of Tonopah, have purchased the old Congress mine and will soon resume operations. J. J. Fairchild, formerly of the Johnnie Con. Gold Mining Co., has been selected as superintendent. This property has a shaft 350 ft. deep, all in ore. The orebody on the 700 level of the Johnnie Con. mine has been defined as 5½ ft. wide, assaying between \$25 and \$30. Sixteen men are now working underground in this property.—Two shifts are working on the Frost-Rathborne lease on the Johnnie Con. ground sacking ore on the 40-ft. level.—The Bullfrog-Johnnie Co. has put a crew of men at work sinking a shaft on the Anna M. claim to determine the strength of the Blue Bell vein, the outcrop of which indicates that it extends into this ground.—Work has been started on the Clanahan mines by W. S. Smith in the Mineral Flat country. The property has a galena vein and assays from \$100 to \$150 in gold and 20 oz. silver.—L. L. Patrick, manager of the Florence mine and a magnate of Goldfield, has purchased a group of mines on Mineral Flat.—The Leadville-Johnnie has a force at work prospecting the Last Chance claim, which has recently shown some rich stuff. This is in addition to the regular work on No. 2 shaft.—In the Globe, work is still confined to the lower tunnel. The new shaft is being sunk on an extension of the Johnnie lode, which shows 5½ ft. of ore assaying from \$10 to \$15.—The Frost-Rathborne lease on the Johnnie Con. ground is sacking rich ore from the surface. They evidently have an extension of the Globe Treasure vein.

Johnnie, October 3.

WHITE PINE COUNTY.

The Nevada Consolidated Co., which is doing so much toward the development of the Ely copper district, is involved in an action in the District Court relating to the title of six important copper claims known as the Chainman group. This property, located in the centre of the productive area, is valued at \$500,000.

BRITISH COLUMBIA.

A serious situation is developing in the Boundary district as a result of the strike in the Crows Nest coal mines at Fernie, B. C. The shortage of coal is becoming a serious menace both to the smelters and also to the mines dependent on them. The Granby reduction works alone consume 300 tons per day and the stocks are exceedingly small. Efforts are being made to meet the demand from Washington and Vancouver Island, but it is probable that the smelters will be partially, if not wholly, closed down unless some compromise is immediately arranged between the miners and operators at Crows Nest. A great number of mines would be effected if ore could not be accepted by the custom smelters.

Personal.

J. PARKE CHANNING is in Colorado.

CURTIS H. LINDLEY is at Ely, Nevada.

R. GILMAN BROWN is in Chihuahua, Mexico.

WILLIAM BLACKMORE is examining mines in Norway.

T. R. HENAHEN has returned to Silverton from Missouri.

J. P. SIDWELL has returned to Chicago from Ouray, Colorado.

H. DEC. RICHARDS is at Orleans, Siskiyou county, California.

J. B. JENSEN, of Salt Lake City, is in the Greenwater district, California.

C. M. FULLER has returned to Denver from a professional trip to Kentucky.

ARTHUR LAKES has been examining mines in Gunnison county, Colorado.

W. L. AUSTIN will be at San Francisco on October 16, on his way from Butte.

CHARLES BUTTERS has returned from Europe. He goes to Salvador next week.

M. T. CHESTNUT and son, of St. Louis, Mo., are now living at Durango, Colorado.

E. M. RAY, of Los Angeles, Cal., is engaged in professional work in Idaho and Montana.

H. B. WARREN has been appointed manager of the Northern Mines Ltd. at Atlin, British Columbia.

HOMER WILSON is now superintendent for the Centennial-Goldfield Mining Co. at Lida, Nevada.

R. R. LESLIE has resigned as superintendent for the Creston-Colorado Mining Co., in Sonora, Mexico.

W. E. THORNE has closed down the Snow Storm hydraulic mine at Alma, Colo., for the season and returned to Denver.

J. D. BEEBE has returned from Alabama and accepted a position with the Lenawee Tunnel Co., at Montezuma, Colorado.

W. H. HOLMES has returned to Denver from Silver City, New Mexico, where he has been to report on mining properties.

THEODORE J. HOOVER has been appointed technical manager for the Minerals Separation Ltd., with an office at 62 London Wall, E. C. London.

R. L. LLOYD has accepted an appointment as metallurgist to the Braden Copper Co., in Chile. He sailed from New York for Valparaiso on October 6.

T. A. RICKARD has been appointed delegate at large to the American Mining Congress by President Roosevelt. He will attend the Congress, which meets at Denver on October 16.

JOHN M. DAUGHERTY, of Omaha, JAMES W. NEILL, of Butte, Mont., and THOMAS A. VARDEN, of Sacramento, have been looking over the properties of the American Mining & Development Co., at Kennett, Shasta county, and San Juan, Nevada county, during the past week. Mr. Varden is general superintendent for the company, and Mr. Neill is consulting engineer.

Obituary.

JOHN C. HENAHEN died at St. Joseph's Hospital, Denver, Colo., on September 21. The deceased was well known as a mining and smelterman throughout Colorado. He was at one time with the Grant and Arkansas Valley plants at Leadville, and later with the American Smelting & Refining Co. He was forty-six years of age at the time of his death. He is survived by his brother, Thomas R. Henahen, of Silverton.

WM. H. RUSSELL, an old-time California and Nevada miner, died at Chilpancingo, in Guerrero, Mexico, on September 30. 'Bill' Russell — as he was generally known — came to Mexico in December, 1903, and had charge of some part of the Guerrero Development Co.'s work up to within a few days of his death. He intended to return to California this month, but was taken ill suddenly.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE new copper district of Greenwater is situated in the desert portion of Inyo county, California, about 60 miles south of Bullfrog, Nevada.

THE efficiency of a rock-breaker falls off rapidly when a reduction exceeding 4 to 1 is attempted, say, 8 to 2 in. cubes, and the same rule holds good for rolls.

FOR practical purposes it is safe to assume that a 9 by 15 in. Blake crusher, run at 250 rev. per min., will break to 1.5-in. size about 5 to 7 tons of quartzose ore per hour, with the consumption of 15 horsepower.

THE belt-conveyor is, for many purposes, the most efficient of the machinery used for conveying. It requires the least power to drive; its first cost is moderate, and the expense for repairs is comparatively small.

THE diamond-drill may be used for prospecting work in almost any kind of formation, and when the prospecting is carried on systematically, reliable results may be obtained at a minimum of expense by use of the core-drill.

THE cost of drying ore depends upon five factors: The percentage of moisture contained; whether fire-gases can be passed through it without injury; whether the ore be sandy or clayey; its ignition temperature; and, finally, the degree of dryness required.

THE simplest form of ore dryer is a series of cast-iron plates placed over a flue so that they will be heated below by the hot gases from the fire-place, each plate having a flange at its sides through which adjoining plates can be bolted together if desired.

THE cost of excavating earth with pick and shovel, and loading it, is about 40c. per cu. yd. for hardpan; 20c. for tough clay; 15c. for ordinary clay, gravel, or loam; and 12c. per cu. yd. for light, sandy soil—wages being reckoned at 15c. per hour in each case.

TO FACE the glare of a furnace or to protect the eyes from excessive light, it is not necessary to use colored spectacles or smoked glasses. Protection can be secured by making a small aperture in a sheet of paper or cardboard, using a pin or pocket-knife to make the hole.

AN effort is now being made to reform the ways of the Patent Office, which is far behind in its work. The Assistant Commissioner of Patents is lending his aid, so that it is hoped to remedy conditions that are detrimental to the interests of investors and industrial corporations.

As a general thing the heavier wire is better for screens when treating coarse, gritty ore, but for soft, clayey ore, likely to choke the screen, the finer wire is preferable in a dry-crushing mill. For coarse screening, say down to 0.25-in. openings, perforated steel-plate trombels of circular section give the best service.

THE answer to the question asking how many miner's inches of water can be carried through 9,000 ft. of pipe, the first 1,600 ft. of which is 18 in. diam. and has 90 ft. fall, and the remainder 11 in. diam., with a fall of two inches to the rod, is: Between 200 and 250 California miner's inches, depending on the kind and condition of pipe.

THE statement that a crystal of calc-spar consists of carbonate of lime, is quite true, if we only mean that, by appropriate processes, it may be resolved into carbonic acid and quicklime. If you pass the same carbonic acid over the very quicklime thus obtained, you will obtain carbonate of lime again; but it will not be calc-spar, nor anything like it.

IN order to increase the speed of a small engine that is running a stamp-mill, lag the driving pulley with a piece of belting so as to give the extra speed. Some throttling governors have a loose pin, so that by merely adjusting that, the speed can be changed. Another way would be to alter the governor pulley so that it will give the same speed of governor for a higher speed of engine. But the question always arises whether the steam-pipe and ports are sufficiently large to carry the steam without too much wire-drawing.

IN REGARD to the best method of keeping a record of the time lost in stamp-mills, we give that used in the Standard mill (at Bodie) when under the direction of R. Gilman Brown. On the post of each battery a pad is tacked; on this the millman records the time lost, noting the cause for each stoppage. Every day the head man reports to the office the time lost for each battery, proportioning the loss to the several causes. This daily sheet has a line for each battery, and would appear somewhat as follows:

Battery number.	Hours run.	Hours lost.
1	22.30	0.30 dress plates, 0.40 lace belt, 0.20 set tappet.
2	22.00	0.30 " " 0.40 " " 0.50 tappet and screen.

Words in italics are printed, the others are written. It was intended to have a list of normal causes printed at the foot of the blank, with a letter or contraction for each, and simply use these in place of writing in full. In the office, the causes are segregated into certain natural categories corresponding to headings in the large office-sheet for the month, and they are entered daily in accordance with this system. All other details, such as renewals, supplies used, new shoes and dies, etc., are also reported on the daily sheet, and entered on the office sheet. The system is simple, and has answered all the requirements at the Standard.

IN REGARD to the treatment of a low-grade copper ore, calculating the copper as chalcopryite and the balance of the iron as pyrite, the data furnished give an approximate partial analysis of 4% Cu, 20% Fe, and 23.4% S, making a total percentage of 47.4, leaving 52.6% to be accounted for. This 52.6% is probably silicate of alumina or silica. If the iron is present as pyrite it is probably not very strong in structure and the run-of-mine ore is likely to contain much fine stuff. The present practice is to screen out the fine ore up to about one inch size, the undersize going to roasters and the resulting calcine is smelted in reverberatory furnaces. The oversize should be smelted direct in blast-furnaces. There are several questions which would have to be considered before determining the proper metallurgy for this ore. The analysis is similar to the second class Bingham pyritic ore, although higher in Cu. Water concentration would hardly be considered, especially if some of the remaining 52.6% should be CaCO_3 . With wood as fuel the entire run-of-mine ore should be crushed and rolled to about one-inch size and then roasted and the calcine smelted in reverberatory furnaces. Wood can be used as fuel in reverberatory furnaces with success. At Trail, B. C., in the early days, wood was the only fuel used in the reverberatory furnaces. It would also be wise to look up the manufacturer of producer gas from wood. In Mexico producer gas manufactured from wood has been used successfully in power plants.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Who Is a Mining Engineer?

The Editor:

SIR—In your issue of August 4 a letter, dated London, July 13, 1906, and signed 'Viator,' deals with the subject of mining quacks. The article gives the impression that the writer considers a full course in a college or school of mines indispensable in the making of a competent mining engineer; that without this training it is impossible for anyone, no matter how well endowed by nature in the gifts of reasoning power, perceptive ability and general common sense to become that—to some persons at least—vague, ambiguous quantity, known as a 'mining engineer.'

Speaking from the standpoint of one whose early technical education was neglected to such an extent that he does not know, off-hand, the meaning of the word which our London friend has chosen for a *nom de plume*, and who is furthermore an "ex-day's pay man," I venture to state that if a prescribed course in some college or mining school is the only avenue whereby a man may become entitled to the distinction of being considered a mining engineer, many of our best men in the mining business today would be unknown and their many merits and obvious worth unrecognized.

It is practically impossible for anyone who has passed that period of life when the luxury of a college course is usually indulged in, to enter school, do the term, and obtain his degree. What then, I would ask, is the man going to do who has been thrown upon the world and compelled to battle therewith to wrench therefrom a living, and who has nothing but his natural faculties and possibly the three Rs for an education?

If in the course of time he feels within himself a desire to climb to the higher planes of the mining business in which, by accident or design, he is engaged as a "day's pay man," and develops a thirst for knowledge along technical lines, is he to be compelled—by the limitations of his early schooling—to stand idly by while others, more fortunate in that regard, pass on and grasp the prize he feels should rightfully be open to him to compete for? Must he renounce and forego forever the cultivation of his mind and desist from acquiring information of a technical character because, forsooth, it has been declared by some person or body of persons that he may never embellish his name with the mystic characters M. E., and no one must take his word or his opinion for anything in mining matters on that account? As one who has served a long and tedious apprenticeship in the ranks of the toilers and who has, by dint of hard work and some perseverance, acquired at least a modicum of this much coveted fruit of the tree of knowledge, I beg to answer No! a thousand times No! If a man is worth the candle that feebly illuminates his place of work in a mine he will be quick to recognize the benefits that come of a technical education and will never rest until he has acquired at least a working knowledge of the technology of his business, and when he has done this I feel bold to declare that he is a better mining man and his opinion entitled to far greater respect than many of the listless, careless bunches of nothing that are turned out of our mining schools by the thousand every year and turned loose upon an unsuspecting public. True, they have run the gauntlet of professors and instructors and passed the examinations more or less creditably and can answer set questions on the various subjects embraced in their course

very glibly, but their M. E. does not amount to a continental until they have gone forth and gained an intimate acquaintance with their business by coming in contact with the various phases thereof in actual practice and then give evidence of an adaptability for it.

Too many of our school of mines graduates had their profession chosen for them, and willy-nilly, they had to get in and dig at it and obtain their degree. In some cases unquestionably the selection of this business was a wise one, while in many instances the results would seem to indicate that a very serious mistake had been made, hence many of our misfits and nondescripts. In the case of our "ex-day's pay man," however, the case is very different. If a common miner thinks enough of the business, after having had perhaps many years of practical experience, to buckle down, of his own free will, to try and assimilate the hard dry facts pertaining to the theoretical side of mining, I think it is comparatively safe to assume that he is anxious to advance and to know whatever is worth knowing about the subject. Is it unreasonable, then, when he has qualified himself along these lines, that he should demand recognition among the other members of his profession? I think not, and I have yet to find a man who has attained any distinction as a mining engineer—in all that the term implies—who would refuse to recognize merit in a fellow worker simply on account of the fact that the latter had not had the advantages of a college education.

If my opportunities for meeting representative men of the mining profession have been so limited that I may not be permitted to form a proper conception of the way they feel on this matter, I hope I may never be undeceived, for I would very much dislike to be compelled to lower the high estimate in which I have been led to hold these gentlemen.

As to the probability of an incompetent ignoramus with a love for the use of "a multiplicity of high-sounding technical terms" deluding a business man, with money to spend and able to pay for the advice and opinions of a mining engineer, the idea seems to me to be too absurd to require a denial. Any man with the average amount of horse sense would readily see through such a palpable fraud as that of a man using language of that nature and terms indiscriminately jumbled together without rhyme or reason, and would know at once the kind of people he was dealing with. No sensible, intelligent human being would be fooled for an instant by a report so obviously ridiculous and self-contradictory as the one quoted by your correspondent and such a contingency, or the chance of it may, I think, be dismissed as not being sufficiently likely of occurrence to cause any alarm.

Going back again to the degree: As you state in your comment upon the article under discussion, the degree conferred by the college or school merely shows that the academic education has been acquired. It is, however, only the alphabet of a thorough mining education. No one would be chump enough to attach any value to the vaporings of one of these fledglings in regard to mining matters. The graduate is more than apt to find that many of the lessons taught in school were illustrated by ideal conditions, and when he goes out to fight and to conquer for himself, it will be strange if at first he does not fail to find things just as he had expected. Then it is that he finds the need of some practical education. This, of course, will come in time; but it takes time. He will find himself confronted by problems that the text-books do not seem to handle, and, as well as he remembers, the instructors must have overlooked; then, cast upon his own resources, he is obliged to put on his thinking cap, and, with the hard concrete facts before him, work

Three Weeks in Mexico---VII.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

Mexican mining terms are frequently distinguished by their aptitude. The hanging wall is called *alto* (high or up), the foot-wall is *bajo* (down or low). But in El Oro I found that the natives spoke of the hanging as *reliz* (pronounced like release). It is a word signifying a landslide or slip, and as suggesting a plane of parting or what a miner calls a 'shooting course,' it struck me as excellent. The hanging is also described as *reliz arriba*, or *arriba* by itself. Waste is *tepetate*. All stringers are called *hilos*, *hilo* being a thread. Ore that is speckled

it to the hanging. These tap chutes wherever practicable, but if the ground near a chute has caved, then a new raise (from the lateral drift) is made to serve the purpose of extracting ore. Finally, when even the foot-wall begins to be bad, a lateral drift is run in the foot-wall country itself, and this sometimes finds unsuspected occurrences of ore.

Another procedure is to leave about twenty feet of ore above the top of the hanging-wall drift; the arch of ground being removed upon the final exhaustion of that block of ore. This method is employed when the maintenance of a roadway is vital, especially when approaching a shaft.

It is instructive to note that while the operating expenses at the Esperanza during 1904 represented 74% of the production, after the bonanza was struck the proportion of expenses decreased to 37%. The diamond-drill cut the new West vein in August, 1904, and the discovery was referred to by Mr. R. T. Bayliss at El Oro annual meeting in October, 1904, but the big rise in Esperanza shares did not begin until the spring of 1905. The story of the discovery illustrates anew how deceptive a single cross-cut can be. The West vein was cut by a cross-cut on the third level at a point 150 ft. north of the south boundary of the mine; the ore was poor, about 15 inches of stuff assaying 17 grams gold per ton. Next it was intersected in a drill-hole 900 ft. north of the place just described, but on the fourth level. Here also it was poor, about 18 inches, assaying 12 grams. This was done by the former Mexican company about four years before the eventual ascertainment of its real value. In August, 1904, the drill-hole put out by the new management, at the fifth level, cut the northern portion of the orebody and found 22 ft. of an average value of \$37 per ton. But the cross-cut which was started at once on the track of the hole cut an 11-ft. vein assaying \$75, the probable explanation being that the drill followed a cross-stringer connecting a poor vein 5 ft. thick to the 11 ft. of rich ore, there being 6 ft. of shale between them, so that the 22 ft. of core assayed \$37 per ton.

The discovery is creditable to the management, as it was owing to their good judgment in the use of the drill. Now two drills are kept in constant use, although this manner of testing the ground is expensive because the quartz is

hard on the carbons. The average cost is 5 pesos per foot of $\frac{1}{8}$ -in. core. A Sullivan E drill is used, capable of drilling 400 feet.

In the Esperanza mine, it is the custom to extend main drifts in the ore, which is hard and stands well. Although the shale is softer, it is found economical to keep within the ore, because this practice obviates timbering as the drift progresses. When the drift has been advanced the desired length—a month's or even two months' work, at 65 to 70 ft. per month—the ore is taken down on both sides and double drift-sets are put in place. When mining near the big fault, skillful work is required. On the upper levels the shattered ground is narrow, but this evidence of faulting increases, so that while it is barely one foot wide on the first level, it is 20 ft. wide at the fifth, where it is dangerous. In order to traverse this ground, not only is spiling required on top, but also on the side of the drift. The set is put in place in the customary manner, with cap, blocking and bridge, so that it looks like Fig. 1. The 'bridge' serves as a resting place for the spiling poles and allows space underneath for driving. Pointing the spiling upward and sharpening it

Placing Timbers in Position in the Stopes.

with black sulphide is known as *mosceado*, or fly-specked, *mosca* being a fly.

The ore, as it comes from El Oro mine, is handled expeditiously. At the main (incline) shaft there are two gyratory (Comet D) crushers, the oversize from which goes to a jaw (Reliance) breaker, 9 by 15 inches. Thence the ore passes into bins and from them it is fed onto a (Robins) belt-conveyor, which is made in sections as demanded by the length (about 200 yards) and the slope to the mill. At the mill the ore is delivered by the conveyor to a traveling tripper which distributes it automatically into the bins; the tripper moves over the bins the entire length of the mill and then returns.

When opening up ground previous to stoping, it is the custom to run a main drift in the middle of the hanging-wall orebody, leaving ore on both sides up to the top of the timbers constituting the drift-set. Then stoping begins above the drift for the full width of the orebody. When the ground begins to weaken and re-timbering has been carried as far as practicable, the stopes will be about half way up to the next level; then the drift in the foot-wall orebody is utilized, by driving cross-cuts from

from one side, tends to lift the soft rock. When the spiling has been pushed on top and at sides, it is driven either with a sledge-hammer or, if that is ineffective, with a ram. If the roof-spiling needs this treatment, the ram is put on rollers. This ram is a piece of 8 by 8 in. timber, from 8 to 10 ft. long, so as to get a good run with it over rollers; if it is to be used for driving spiling near the floor, the ram is suspended from a roof-timber and thus it gets a swing. If the ground commences to run,

Fig. 1.

the face is bulk-headed with 4 by 12 in. or 6 by 12 in. planks, according to conditions. These breast-boards are then blocked by spiling, both on top and sides; the next step is to advance them. If the bottom one is advanced first, the ground would run, but if the top one is pushed, there is nothing to escape, because the top spiling holds

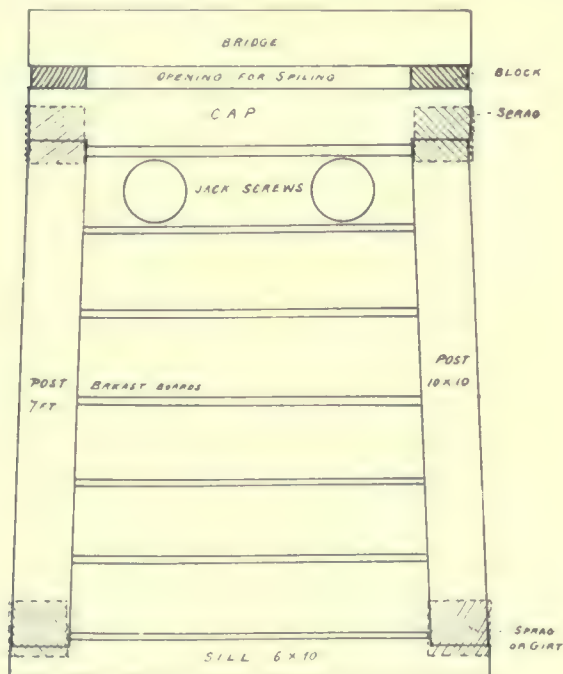

Fig. 2.

it back. Therefore, two jack-screws are brought to the spot and they are placed with heel (or base) on a cross-timber carried by the rear set. The top breast-board is now advanced 8 or 12 inches and a sawed-off block is inserted within the space thus obtained; this block holds the breast-board in its advanced position. The next board is pushed to a corresponding position, as before, cleaning

out the cavity made, the soft ground being taken out over the top of the next lower board. This procedure is repeated with the other boards until they are all in line, marking a permanent advance of 8 or 10 inches or more, as circumstances permit. This is position No. 2. On the next advance, longer blocks are used to keep the breast-boards in place and the work goes on until room has been made for another set.

The north shaft is sunk through bad ground, particularly a length of 200 ft. between the third and fourth levels, and another stretch from the eighth to the ninth. There is a creep of 15 inches per annum, and it is found necessary to renew the timbering every nine months; this is done by a gang of *peones* specially trained under a Piedmontese foreman.

Double sets are used for timbering main drifts; all

Special Shaft Set; 14-In. Timbers.

the caps are double-locked to prevent splitting and, in rare cases, even the sills are double, when the ground underfoot tends to rise. In such cases an intervening block of ten inches is inserted, the bottom sill being the first to break. Ordinary sets would last only 60 days, the double sets are in service for 12 months; the top set

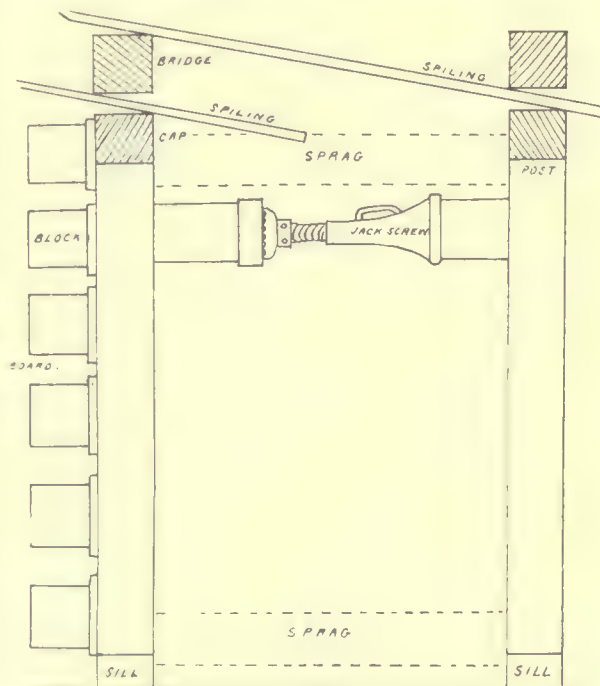

Fig. 3.

takes the weight and yields, without affecting the usefulness of the drift. The lower set remains unimpaired, until finally it is pushed too hard; then the pressure is taken by the erection of a false set, which, while the lower set is being replaced, does service as a top set.

In bad ground it is the custom to leave from three to four inches between the lagging, so as to permit the

soft ground to come through, but not enough to block the tram-track. After this the ground is not eased further until the lagging breaks; it is then replaced by fresh

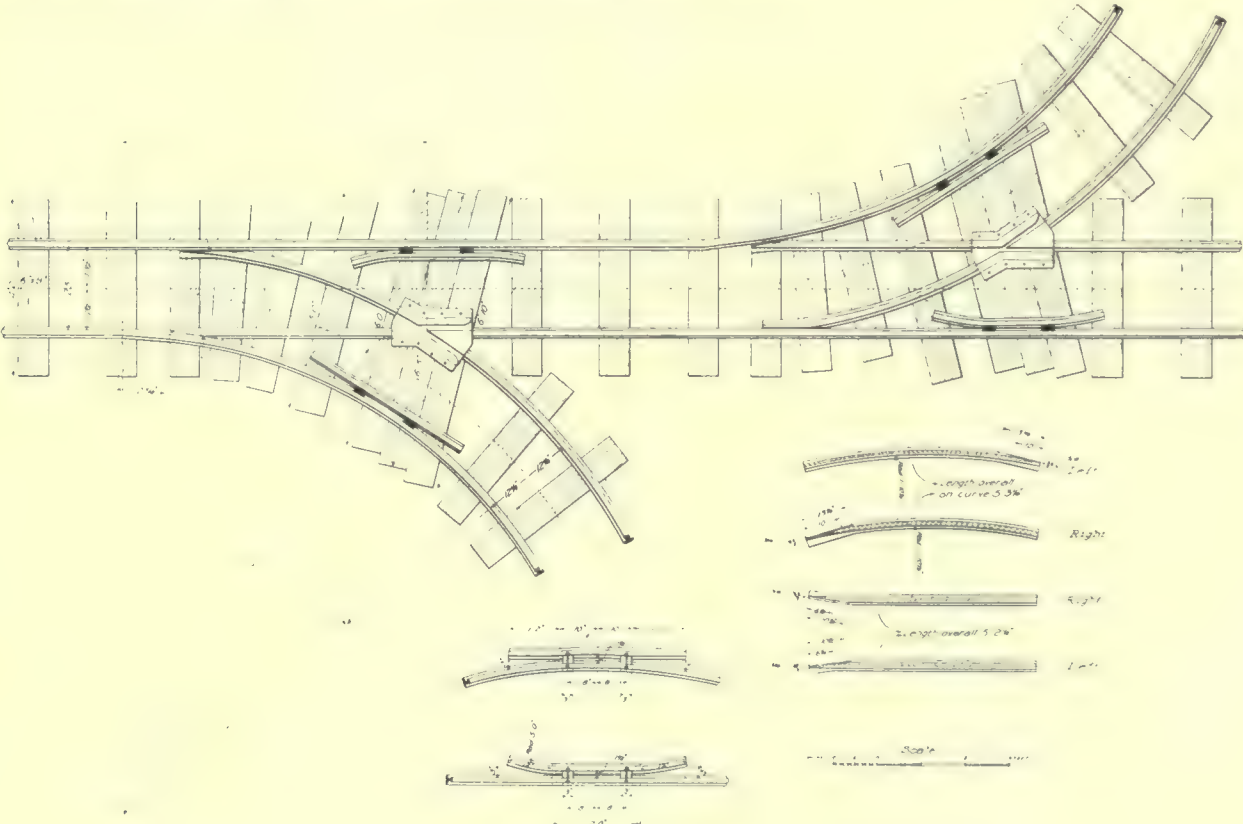

get relief of pressure by pushing through the lagging, the space between poles is six inches. Close lagging requires more frequent renewal, but it eases the timbers. By

Split Switch. Mine Locomotive Track.

poles. If the weight is from overhead, no effort is made to ease the pressure, which is allowed to break the timbers, to be replaced by fresh sets. The choice is between

allowing the sides to break through, more weight is thrown on the timbers, by the enlargement of the arch of ground overhead.

Fixed Switch in Mine Track.

losing time in cleaning the track or letting the timber stand as long as possible before renewal. It is held that the question of blocking the track is paramount in a mine producing so large a tonnage of rich ore. Where it is the intention to encourage the ground to

Stope-sets are 5 ft. from centre to centre, with a height of 8 ft. They are so placed as to oppose the tendency of the walls to close, and the consequent strains are all accepted on the end of timbers. Great care is taken with the tracks and admirable sys-

tem is exhibited in the arrangement of them. The cars weigh 1,100 lb. each and carry 2,200 lb., the total weight being 3,300 lb. The gradient is a half of one per cent, that is, it is such that the labor of pushing an empty car up-grade or of pushing a full car down-grade, is approximately equal. The width of track is 23 in., or 60 cm., the gauge being based on the metric system. The rails are 20 lb. per yard, and of Carnegie cross-section. The minimum curvature adopted throughout the mine is a 12-ft. radius, for which standard cast-iron right and left-handed frogs are used. Switch-points are carefully made in the Esperanza company's own shops; the points themselves being reduced in a planer instead of the customary blacksmith shop. All of these precautions tend to assure easy handling of heavy cars by inferior native labor. Special tools are provided for bending and punching the rails; all curves are laid to template. The ties are 2 to 2½ ft. apart and are made of 6 by 8 timbers. On curves the gauge is widened 1½ in., and the

Square Set. 8-In. Timbers. Side Elevation and Details.

inside of curves is protected by a guard-rail; the same protection is provided at the points of all frogs. When using hand-cars, fixed points are laid down; but where electric motors run, the switches are made movable.

The Esperanza company maintains elaborate assay-plans. There is one for each floor in the stopes, the floors being 7½ ft. apart. On each plan the timber sets are marked in 5 ft. squares, every month's work is indicated by a different color and in every set the assay-value of that square of ground is marked in figures indicating grams of gold per metric ton. There is no assay for silver because the ratio between the metals is known from experience; in oxidized ore it is 6½ grams of silver to 1 gram of gold; in sulphide ore the proportion is as 15 to 1. Every car loaded with ore from a chute is grab-sampled at the shaft-station, the assays thus obtained giving the average value of the mine-output for that day, while the number of cars gives the quantity. Thus 350 mine-assays are made per diem, and these also enable the foreman to keep a check on the kind of ore being broken. Gangs

of samplers, in pairs, test daily each working face in stopes and drifts; a sampler within the space of one set will get a chance to test more than one face, sometimes three of them. Both the moil and the pick are used; the ore is broken onto canvas spread underneath; the samples average 50 lb. apiece and are quartered down to 5 lb. each, before they go to the sampling room at the assay-office. All these returns are compared with the battery sample from the mill.

Taxes are heavy at El Oro. They amount, for instance, to 13% on the gross output of the Esperanza mine, but this includes State and Federal taxes, import duties, and the care of troops stationed in the district. On bullion the mine pays 2½% to the Federal Government and 1½%

Square Set. 8-In. Timbers. Plan and Elevation.

to the State.* All State taxes are subject to a second imposition of 25%, which goes to the Federal department. There is a wage tax, so much for each man on the payroll; there is a stamp-tax on every recorded business transaction; and there are duties on imports, particularly on dynamite.

On dynamite there is a tax of 243 pesos per ton. El Oro mine uses 185 cases, of 50 lb. each, per month. The Esperanza mine consumes 400 cases, or a carload in six weeks, so that the tax weighs heavily. It is intended to compel the mining companies to use the domestic dynamite; but the Mexican company's factory was blown up twice and they had ceased to manufacture at the time of my visit; nevertheless, according to the terms made with the Government, they had to furnish 60% dynamite at 19.34 pesos per case of 50 lb.—a rate fixed by the Government, as against 16.34 pesos, the old price. While the factory was in operation it cost 29.67 pesos to import the

*Gold, however, is now being purchased by the Government, and on bullion parted and refined in the country the Federal tax on gold has been removed, while the silver tax is reduced to 1½ per cent.

explosive from the United States; the company (Mexican National Dynamite Co.) was furnishing (in October, 1905) American dynamite for 19.34 pesos, but as soon as their factory resumed, it was expected that they would sell their own product at the same price. Americans mining in Mexico consider it to be unsafe and usually prefer to import dynamite at 29.67 pesos. Recently one of the leading companies at El Oro has made arrangements to buy from the monopoly, which furnishes American dynamite at about the same price as paid formerly. The management could not import the American powder direct, however, without paying the increased price. The monopoly is allowed to charge 16.79 pesos for 40%; 18.07 for 50%; and 19.34 for 60% dynamite.

The electric power used at El Oro comes from the Necaxa plant, on the river of that name, 176 miles distant. At the time of my visit the line was nearly completed. It has been built by Canadian capital. Mexico City is supplied with the same power, the distance being 100 miles from the falls to the city and 76 miles from there to El Oro, over the wires. There are eight circuits of three wires each between Mexico and Necaxa, and two circuits, also of three wires, from the city to the mines. Fifty thousand volts are delivered at El Oro, by a three-phase system, and it is expected that there will be an 8% loss to the city and an equal loss thence to the mines. The current does not go through a transformer at Mexico. Power is generated under a head of 1,450 ft. by a vertical-shaft turbine with the generator on top; the wheel is the invention of Escher Weiss, at Zurich (Switzerland). The hydrostatic head at Necaxa has been obtained by the building of an earth dam, 185 ft. high, 1,500 ft. thick at the base and three-fourths of a mile long; it holds 55,000,000 cubic metres of water and backs the river $2\frac{1}{4}$ miles. The transmission cable has a jute core and consists of six strands of No. 6 wire equivalent to No. 000 wire or 0.229 in. The power is sold to the mining companies on a sliding scale, the prices being graded according to the amount consumed, the lowest price being \$50 per horsepower per annum to those consuming over 1,000 horsepower. Several times the natives have cut down the wires and stolen them, on two occasions as much as a kilometre was removed. This has been exaggerated by rumor to seven or eight kilometres. As soon as the cables were erected, a small current (generated by a steam plant at Mexico City) was put on, in order to prevent stealing; the result was that several *peones* were killed. Later, when one line had a current and the other not, the thieves seemed to know enough to distinguish between the dead line and the live one. The copper stolen is cut up and sold to the junk shops.

MELTING POINTS OF METALS.—Ice melts at 0° C. and 32° F.; under 760 mm. pressure it boils at 100° C., or 212° F. According to J. A. Harker, of the National Physical Laboratory, the following data give the melting points of the metals named:

Metal.	Degrees Centigrade.	Degrees Fahrenheit.
Tin	232	449
Lead	327	620
Zinc	419	786
Antimony	632	1,169
Aluminum	657	1,214
Silver	955	1,751
Gold	1,064	1,947
Copper	1,062	1,943
Nickel	1,427	2,600
Iron	1,503	2,737
Platinum	1,710	3,110

THE famous Burra Burra copper mine, in South Australia, is to be re-opened after 30 years of idleness. Five parties of tributers have started to work.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

THE drill-cores marked E. J. B. from Velardeña, Mex. are quartzite containing pyrite.

THE mineral from Santa Ana, Cal. marked W. W. H. is compact green chlorite containing nothing of value.

THE bluish tarnish on the pyrite crystals from Quartz, Cal. marked G. L. E. is probably due to a slight oxidation of the sulphide.

THE rocks from Shoemaker, Los Angeles county, Cal., are: No. 1, Garnet; No. 2, Serpentine; No. 3, calcium carbonate (both pieces).

THE rock from Lakeview, Ore., marked L. H. H. is quartzite. If precious metals are present the amount can be determined by an assay.

THE mineral from Hamil Station, Mono county, Cal., marked F. C., is silicious iron ore, containing sulphide and carbonate of copper—sink on it.

Rocks from Spokane, Wash., are: No. 1 and 2, Quartzite containing copper sulphide. The brown patches are also Quartzite stained by limonite. No. 3 is Graphite.

THE rocks from Chloride, Ariz., marked M. C. are: No. 1. Feldspar-porphry; No. 2. Quartzite; No. 3. Aplite or granite; No. 4. Biotite-quartz-diorite; No. 5. Rhyolite-porphry; No. 6. Granite; No. 7. Diabase; No. 8. Biotite-granitite; No. 9. Diabase; No. 10. Altered rock probably rhyolite, with biotite crystals.

THE mineral specimens from Spokane, marked A. R., are: No. 1. Cellular quartz with limonite stains; No. 2. Limonite resulting from the alteration of an iron-bearing mineral, perhaps pyrite; No. 3. Carbonaceous schist; No. 4. The yellow mineral is siderite. The other questions can only be answered from a knowledge of the local mineral occurrence.

THE rocks from Ibapah, Utah., marked J. S. L. are: No. 1. Hornblende-diorite. No. 2. Quartz-mica rock containing black crystals of tourmaline, probably an altered pegmatite; No. 3. Hornblende-biotite granite; No. 4. Rhyolite. No. 5. Rhyolite, altered and stained with red hematite; No. 6. A hydrous magnesian silicate, allied to serpentine; No. 7. Cuprite, the oxide of copper with malachite and chrysocolla; No. 8. Native bismuth.

THE rocks from Slocan, B. C., marked W. C., are very much decayed and determination is accordingly difficult and uncertain. No. 1 is Diabase; No. 2 is not a typical rock. It was evidently a basic rock of some kind—probably diorite—but it is now altered to a nondescript mass of argillaceous and chlorite mineral; No. 3 is Talc-schist; No. 4 is much altered, but was originally a coarse Quartz-diorite; No. 5 is similar to No. 4, but has suffered more from surface decay; No. 6 is Diabase; No. 7 is Quartz-mica-diorite; No. 8 is a silicious dike rock and has somewhat the appearance of ore; No. 9 is a dark-colored Biotite-granite; No. 10 is an igneous basic rock, partly altered to Talc-schist; No. 11 is Quartz containing specular iron and pyrite. That marked A is a much altered magnesian rock. It contains considerable disseminated quartz. The occurrence of a fine silt-like limonite in this rock suggests the possibility of the presence of gold; B is similar to A, but still more like ore. C is Feldspar.

Shaft-Sinking With Small Machines.

Written for the MINING AND SCIENTIFIC PRESS
By ARTHUR B. FOOTER.

For the past six months the North Star Mines Co. has been extending its main incline-shaft from the 4,000-ft. level to 4,700 ft. A vertical shaft, 1,600 ft. deep, joins the incline at the 4,000-ft. level, and the skips operating in the vertical shaft continue down the incline, making the turn at the intersection through a curve of 30-ft. radius.

The incline-shaft, with which we are particularly concerned, is 18 ft. wide by 7 ft. high, and has an average

the drills into four three-quarter-inch hose. Twenty-two holes six feet long constituted a round, unless the ground was found too hard to break to this depth, when shorter holes were drilled. These holes were usually blasted at about four or five o'clock in the morning, and by the time the day shift came on the smoke was sufficiently cleared out for them to go to work. It was found that by stopping the sinking pump, the water, rising and covering the face, helped to diminish the gas.

For getting rid of the rock, a single track was laid to within a short distance of the bottom of the shaft, branching there into two tracks to the bottom. These two tracks were kept extended to the face itself by two port-

At the Bottom of the North Star Shaft.

pitch of a little less than 30° from the horizontal. It is in very hard rock, requiring no timber.

The work of sinking was carried on by a day and night shift. The mucking was done by the day shift, consisting of three miners and two car-boys, working from seven in the morning until five in the afternoon, while the drilling was done on the night shift by four machine-men who went to work at six in the evening and worked until they had drilled and blasted a round. This usually took until 4 A. M., but sometimes, if they got a late start, they did not go home until seven, when the day shift came on. The miners were paid \$3 per day, the car-boys \$2.50, and the machine-men \$4.50. Any delay either in drilling or mucking was made up by the machine-men working 'long shift'—from four to seven in the morning—these men getting extra pay, with the understanding that they would do this when necessary. Only twice in the six months was so much time lost that it could not be made up in this way, so that it became necessary to lose a whole shift. Both times it was trouble with the sinking pump which caused the delay.

Four 2½-in. torpedo drills, mounted on four arms on two six-foot bars, were used in drilling, the air being brought to the drills through two one-inch hose branching near

able lengths of tracks, the rail-ends of which were tapered down and provided with wings so they would slide on top of the track already laid, thus making it possible to run a car right up to the face without splicing in short lengths of rail, or waiting until the dirt was all cleaned up. An automatic switch at the branch, thrown by the ascending car, always returned the descending car to the unoccupied track at the bottom. Thus there was always a car at the face being filled, first on one side of the shaft and then on the other, the hoisting rope being unhooked from the empty car and hooked to the other car as soon as loaded. The cars were of the standard round-bottom side-dump pattern used in the mine, of one ton capacity. A small geared engine, run by compressed air, hoisted the cars to the 4,000-ft. level, where they were dumped into the bins and the rock hoisted to the surface in the skips.

The chief departure from the usual practice of shaft-sinking has been in the use of small or one-man machine-drills. It has usually been considered that with small machines the progress would be too slow, although possibly a saving in cost could be effected. It is believed that the following table of progress and costs will show that the speed in this instance is better than that usually

made by the use of large machines, the size of shaft and the nature of the rock being taken into consideration, while the cost is as low as is to be expected with the use of small machines. The figures are given only for the five full months that were run.

	March	April	May	June	July	Average
Feet driven	100	111	120	100	100	106
Tons hoisted	1,545	1,385	1,487	1,593	1,092	1,420
Labor per foot	\$9.93	\$8.32	\$8.18	\$9.00	\$9.06	\$8.90
Powder and candles per foot	3.05	2.65	2.99	3.01	3.20	2.98
Drills per foot	4.47	1.76	3.82	2.27	2.16	2.90
Tools, etc., per foot	2.07	1.03	1.89	1.12	.94	1.41
Tramming per foot	8.54	8.95	7.63	9.13	6.98	8.25
Timbering per foot	1.55	1.78	1.43	1.49	1.32	1.51
Hoisting per foot	2.96	2.63	2.91	2.90	2.07	2.69
Blacksmiths and mechanics per foot	2.83	2.52	2.62	3.33	2.59	2.79
Total cost of mining per foot	\$35.45	\$29.64	\$31.47	\$32.25	\$28.32	\$31.45

Mr. A. D. Foote is the manager of the mine, and the work has been directly under the supervision of Mr. Robert Walker as underground superintendent, and Mr. Richard Barry as foreman.

PORTLAND CEMENT is now manufactured in this country from the following raw materials—cement rock and limestone, limestone and clay or shale, marl and clay, and limestone and blast-furnace slag. In 1905, 52½ % of the portland cement manufactured in this country was made from cement rock and limestone, 36½ % from limestone, and clay or shale, and 11 % from marl and clay. The manufacture of cement from cement rock and limestone is distinctly an American process, but both limestone and clay, and marl and clay, have been used for this purpose abroad. Cement rock is an argillaceous limestone. In New Jersey, for example, the deposit is in a narrow belt about 50 miles long and nowhere more than four miles wide. Cement rock contains from 65 to 80 % carbonate of lime and from 15 to 25 % silica, oxide of iron and alumina taken together. The early cement plants using clay and marl or limestone and clay all followed closely the European practice of cement manufacture, which consisted in finely grinding a wet mixture of marl and clay or limestone and clay and then moulding the mixture into bricks, which were burned in some form of upright kiln. Those plants using cement rock and limestone, however, found it impossible to get the fine crystalline mixture to cohere sufficiently to form briquettes which could be handled without crumbling. At one plant, therefore, a small percentage of cement was added to the mixture as a binder, while at another plant coal tar was used for this purpose. The use of cement rock as a raw material and the employment of coal tar as a binding material constituted the first advancement of American over European practice.

DETERMINATION OF BISMUTH.—A satisfactory method of determining bismuth consists in adding to its solution in nitric acid strong ammonium phosphate solution in slight excess. BiPO₄ is perfectly insoluble and withstands ignition. The filter-paper must be burned separately. In presence of Cu or Cd, some excess of HNO₃ must be used and the BiPO₄ should be boiled with decinormal HNO₃, which is then re-treated with Am₂HPO₄ to recover the trace of dissolved BiPO₄.—L. Moser, *Journal of the Chemical Society of London*, March, 1906.

THERE is a prevalent idea that the constructive genius is in itself something grander than the critical, even though the former turns out to have merely made a symmetrical rubbish heap in the middle of the road of science, which the latter has to clear away before anybody can get forward.

Cobalt.

Written for the MINING AND SCIENTIFIC PRESS
By J. A. MACDONALD.

There is a popular idea that the Cobalt boom is over because some five thousand green prospectors were chased out of the district this spring by a combination of bad luck and black flies. Up to the latter part of July, the black flies, mosquitoes, and sand-flies were so rife that they made prospecting in the thick bush almost impossible. Added to this, the new prospectors, instead of spreading out over the country, confined their operations principally to the area around Cobalt, which has already been thoroughly examined on the surface. Those who hope to make strikes in that vicinity now must trench for discoveries. Any uncovered outcrops were all located last summer.

Another feature which tended to dull interest in the camp was the determination of the mine owners not to ship any more ore to the smelters in New Jersey. Last year they were forced to sell their ore in order to realize enough money to declare dividends and provide for development. But they recognized the fact that it was robbing their mines to send ore to Jersey City, because the smelter paid only for their silver and kept all the rich by-products, such as cobalt, nickel, and arsenic, which are associated with the silver found in Cobalt. This summer, however, all the large mines are storing their output and waiting for the completion of the smelter now being rapidly brought to completion at Hamilton, Ontario. Last month one well-known property had 200 tons stored that would assay from \$1,000 to \$1,500 per ton, and another had over \$1,000,000 worth of ore either broken or blocked out. Meantime most of the companies are clearing the surface of their properties and, in doing so, they are finding rich veins under the grass-roots. In nearly every case a large number of new finds have been made adjacent to the shafts already sunk and some of these are even richer than those that are being worked. The Jacobs company has a new vein exposed for a length of over a hundred yards; this is eight inches wide and almost pure silver. The latest big discovery reported is on the Nipissing property; the vein is alleged to be five feet wide and is uncovered for 50 ft. Prof. W. A. Parks, of Toronto University, who has just returned from Cobalt, is authority for the statement, and is said to have personally measured this astonishing find. The Nipissing company can have no object in putting forth a canard, because that mine yielded \$1,600,000 worth of ore for the year ending April 1. The general result of stopping the operations this summer has been that the score of recognized mines are found to be richer than at first supposed. On the outlying claims around the magic circle of shipping mines, a considerable number of companies are engaged in what the old-timers term 'perpendicular' prospecting. That is, instead of examining the surface of the claims by trenching, they are sinking expensive shafts on insufficient data in the hope of striking it rich down below. The experience of the camp is that unless you can strike it on the surface, there is not much use going down with a shaft. A goodly number of these 'perpendicular prospectors' are likely to lose their money, which, if employed in less spectacular work, might have resulted in success.

A large number of the experienced prospectors, however, have gone north along the Temiskaming & Northern Ontario Railway, which runs through the heart of the Cobalt district, and a strike of gold has been made, about ten days ago, 85 miles north of New Liskeard, assaying several thousand dollars per ton, and a rush for that locality has now commenced. This is the first find

of gold of any importance, and the yellow metal has an attraction very much greater than that of silver.

With the finding of the great big nugget of silver at Cobalt a short time ago, which weighed 800 lb., 70% being silver, worth something over \$5,000, there has been a great rush of people, mostly American capitalists, to Cobalt. Last week a number of New Yorkers, having their own private car, came into Cobalt to speculate. A great many men from across the border, having a little money, come daily to Ottawa with the intention of prospecting for themselves, expecting to hire an experienced miner to go in with them. Last week the proprietor of a milk-sugar factory in central New York left his factory to other hands, and came to Ottawa. Seeking out the

writer, he asked to be put in acquaintanceship with a good, honest prospector to 'go in' with him. Such a man was found, but these prospectors have so many applications of like nature that their terms are almost prohibitive. This prospector demanded from my New York friend a monthly wage of \$50 and a one-third interest in any find, the green man with the money to pay all the expenses, such as the purchase of a canoe, tent, blankets, shovels, picks, and a supply of provisions. The man from New York was a little timid, and thought the 'lay' was too one-sided. He has not yet closed a deal with the prospector. He was assured, however, that a two months' prospecting trip into Cobalt would not cost much over \$200, which is not a large sum to lose even if no finds are made.

Under force of circumstances the Government of Ontario has now gone into mining in Cobalt, the profits to go to the Provincial Treasury. The reason for this is that the Gillies timber limit is a sort of silver elephant on the Government's hands. The Gillies timber limit is a large tract of land, just south of the town, which was sold some years ago to the Gillies brothers, lumbermen, for its timber. It is now known that the Gillies limit contains, besides timber, large quantities of silver ore. Gillies will, of course, be allowed to take the timber, but he has no right to the land or the silver ore therein; and to permit prospectors into this territory would mean the destruction of the timber, and an infringement upon private rights; so the Government of Ontario has decided to develop this area on the fringe of the town for the benefit of the people of Ontario. Undoubtedly there is

great mineral wealth in the Gillies timber limit. On the northeast corner of it there is a silver vein on the surface nearly six inches wide, and very rich. It is only uncovered about 50 ft., but the vein alone makes the lot on which it is situated worth several hundred thousand dollars, just as it stands. This is only in one small corner. That may constitute a mine worth millions of dollars, the output of which may extend over a long period of years. Moreover, it is to be noted that the supposed rich part of the Gillies limit is larger than the whole producing area around Cobalt.

There is no reason why the Government should not dig enough silver out of the vein already discovered to secure funds sufficient to prospect thoroughly the entire tract on

behalf of the people of the Province. The ground has already been clandestinely prospected by hundreds of men in defiance of the law, and if their reports are to be believed, the northern part of the limit has "millions in it." Some of the 'finds' have been staked and restaked a dozen times over, while many of the best discoveries have been covered up, awaiting the day when the Government would open it for legal staking of claims. It is generally conceded that if the tract were thrown open in the ordinary way, there would be disorder and even bloodshed. When the time came to file, every claim would have a dozen claimants, and in cases where millions were involved, endless litigation would cripple

development for a long time. The only feasible solution apparently was for the Government to retain the property and develop the mineral resources itself.

J. F. KEMP holds that water under great load or pressure does not expand according to the 4% rule (that is, 4% for 100° C). On the contrary, it may be held by the pressure at fixed volume, despite the added heat. If, for example, we roughly assume a column of water 1 sq. in. in cross-section and 2 ft. high (it is really about 2 ft. 3½ in.) as equal to a pressure of a pound to the square inch in 10,000 ft., we would have pressure of something near 5,000 lb., or over two tons to the square inch; and in face of this, the expansion of water from an added temperature of 100° C. practically becomes a negligible quantity as contributing to hydrostatic head.

THE great tragedy of Science is the slaying of a beautiful hypothesis by an ugly fact.

The American Mining Congress.

Communicated by its Secretary, J. F. CALLBREATH.

The amendments recently adopted by the American Mining Congress mark the beginning of a new era for that organization. Heretofore its work has consisted almost entirely of holding its annual session, at which matters of importance were discussed and resolutions adopted embodying the consensus of opinion, through the influence of which a number of reforms have been accomplished. With the creation of permanent headquarters at Denver the work of the Congress was enlarged and plans were made for the creation of a permanent exhibit of commercial ores of the whole country, a complete mining library, a laboratory for qualitative analyses, a bureau of information on all subjects in connection with mining, and a compact organization through which the problems of mining might be solved—all these so planned as to help the practical mining man and attract the novice. It is also planned to furnish such information to intending investors as would serve to guard them against palpable frauds, and place mining on an investment rather than a speculative basis.

These plans could not be carried out without considerable expense, and the provision made for the expense of an annual convention only was found to be entirely inadequate. Again it was found that the fixing of permanent headquarters at Denver created the impression that the Mining Congress was liable to become a Denver organization, rather than serve the broad purpose of a national institution with which the mining men from every section of the country could co-operate and to which all could turn for assistance in the solution of those problems which require united action and which are of general interest. Another weakness of the old plan lay in the fact that the Directors, necessarily widely separated and busy men, could not hold frequent meetings, and the responsibility of decision of many matters of importance must of necessity be left to the Secretary.

These problems have been met by the recent amendments providing for an Executive Committee with power to act in the interim between meetings of the Directors, and for the increase of the annual dues from \$2 to \$10, which is believed to be sufficient to meet the necessary expenses; not so high as to prohibit the membership of any reputable mining man and yet high enough to keep out unworthy men.

The third objection was met by an amendment to the by-laws which limits the power of any one State to control the organization. Under this clause Colorado, with one thousand members, would have no greater influence in the selection of the governing body than Oregon, Washington, and Idaho, with thirty members present at any annual meeting. That this amendment should have been passed by the unanimous vote of the Colorado members present at the recent meeting of members, indicates the desire on their part to foster a national organization on broad comprehensive lines.

For the protection of the mining investors of the United States, the American Mining Congress has established a Bureau of Inquiry, through which information can be obtained as to the condition of the property and the standing of the company that has asked or is asking for the money of the investor. This Bureau of Inquiry will be absolutely impartial in its findings, its sole purpose being to prevent ill-advised mining investments and to save the West from the disgrace which follows dishonest mining promotion.

In order thoroughly to eradicate fake promotion, the American Mining Congress is pledged to give to inquiring members information absolutely unbiased, collected

from unprejudiced sources—largely its own trusted correspondents—and to have but one end in view, namely, the protection of the investor, its belief being that every dollar improperly invested is a damage to all legitimate mining, and that the highest good of the mining industry may be served by warning investors against improper investments and furnishing such information as will guide them into channels which give promise of success.

A bill providing for the punishment of all mining fakirs and promoters of illegitimate mining enterprises will be drafted by the American Mining Congress at its annual session which will be held in Denver, Colorado, October 16 to 19 inclusive. A committee has been appointed to prepare and submit to the Mining Congress a draft of such bill. This committee comprises two United States Senators, Robt. M. La Follette (Wisconsin) and Fred T. Dubois (Idaho); one Congressman, Eben W. Martin (South Dakota), and the Governors of two States, Geo. C. Pardee (California), and Jos. W. Folk (Missouri). Four are attorneys and all are from mining States of prominence.

Prevention of Fraud.

The last Legislature of the State of California passed an Act which has now become law, providing that:

SECTION 1. Any superintendent, director, secretary, manager, agent, or other officer, of any corporation formed or existing under the laws of this State, or transacting business in the same, and any person pretending or holding himself out as such superintendent, director, secretary, manager, agent, or other officer, who shall wilfully subscribe, sign, endorse, verify, or otherwise assent to the publication, either generally or privately, to the stockholders or other persons dealing with such corporation or its stock, any untrue or wilfully and fraudulently exaggerated report, prospectus, account, statement, of operations, values, business, profits, expenditures or prospects, or other paper or document intended to produce or give, or having a tendency to produce or give, to the shares of stock in such corporation a greater value or less apparent or market value than they really possess, or with the intention of defrauding any particular person or persons, or the public, or persons generally, shall be deemed guilty of a felony, and, on conviction thereof, shall be punished by imprisonment in State prison, or a county jail not exceeding two years, or by fine not exceeding five thousand dollars, or by both.

SECTION 2. All acts and parts of acts in conflict with this act are hereby repealed.

A German-Canadian syndicate proposes to build a cobalt smelter on the Temiskaning and Northern railway. It is stipulated that the German process to be used must be kept secret, and the experts to be Germans. The works will be started with the wet and dry process, first a concentrating plant to treat low-grade ores, then a cobalt oxide works, and lastly a roasting plant. In Germany 52 per cent of the world's production of cobalt oxide is used, and the German superintendent guarantees a market for 100,000 lb. annually.

THE Koreans make excellent miners and laborers, and they are cheap. An assayer informs us that his furnace-man considers himself well paid at \$4 per month, without board. Miners get from 20 to 25 cents (gold) per day, though even less is paid in certain districts. The Korean as a miner may not be as good as a white man, but he is far ahead of both the Kaffir and the Chinaman. By way of comparison it may be said that four Koreans will do the work of three white men.

Ore Treatment at the Combination Mine, Goldfield, Nevada.

II. The Mill.

Written for the MINING AND SCIENTIFIC PRESS
By FRANCIS L. BOSQUIL.

In considering a mill for the combination mine, it was thought that the size of the property would hardly justify the initial installation of more than ten stamps. The plant, as completed, is unusually large for such small capacity. An extensive and costly equipment was made necessary by the elaborate process required for the best recovery, and by the decision of the management to reserve one-half of the mill for the treatment of custom ore. The latter required one complete and separate unit; thus the whole plant was spread over a greater area than would otherwise have been necessary. The outlay, how-

There are four of these bins for the four units of five stamps each. (Ten more stamps have recently been added for treating sulphide ore.) The point of discharge at the top of the mill is shifted by means of the usual form of adjustable carriage. The ore is fed from hanging feeders, attached to the bins, into the low mortars of the Boss cantilever battery system. This type of battery frame and mortar was described in the MINING AND SCIENTIFIC PRESS, of February 17, 1906.

In the following description of the milling system, I shall first take up the treatment of the oxidized ore, which is carried on by the original ten stamps and cyanide annex. As already explained, the mill was divided into two separate units for the purpose of treating custom ore. Very little custom ore, however, has been received; and recent favorable developments in the mine have decided the management to devote the entire mill to their own ore. In the following account, a complete five-

Mill of the Combination Mines Co., at Goldfield, Nevada.

ever, has been amply justified by the efficiency of the machinery, and the high recovery obtained.

The lack of grade for millsite introduced several problems into the construction which have necessarily affected the cost of treatment, namely, the elevating of ore to the bins, and the elevating of pulp to classifiers. The water problem, however, was solved at the start. The water is obtained from springs situated about ten miles west of the mine, and is pumped to the mill against a head of about 800 ft. at a cost of 0.1c. per gal. It is hot as it comes to the surface and carries about 0.1% sodium sulphate and a trace of sodium chloride. Though slightly brackish, the water is potable; and for milling purposes the sodium sulphate is beneficial in assisting the settlement of the slime.

The ore is trammed from the shaft to storage bins, from which it is delivered to a platform above a 10 by 16 Sturtevant roll-jaw crusher, where it is mixed with the required amount of lime, varying from 5 to 10 lb. per ton. The crusher reduces the ore to about one-half inch size. The lack of fall made the interposition of a sorting grizzly impossible. Everything passes to the crusher and is delivered direct to a 12-in. belt-conveyor set at an angle of 20°, which elevates the ore to the mill-bins.

stamp system will be considered. The scheme of treatment is exhibited diagrammatically in Fig. 1.

Inside amalgamation is carried on by means of a curved plate screwed to the chuck-block. The ore is crushed through 12-mesh wire screen. Outside the screen a splash-plate is used. From this plate the pulp falls to a lip-plate about 12 in. wide, with the front edge slightly bent down, giving the pulp a gentle drop to the apron-plate. There are three plates to each mortar, arranged in steps, giving an amalgamating surface 53 in. wide and about 12½ ft. long. The whole tray, by means of wheels and track, can be shifted during the clean-up of the battery, as shown in Fig. 2 and 3.

At the bottom of each tray is a small cone hydraulic classifier, which separates the coarse mill-pulp into two products: (1) Fine sand and slime, which passes to the outer discharge lip of the Bryan mill and thence direct to the concentrators; (2) coarse sand, which passes to the Bryan mill for re-grinding.

The ore being extremely hard and tough, is crushed with 1,350-lb. stamps, falling 100 times per minute, with a 6-in. drop. In spite of this, however, the stamp-duty is only 3½ tons, using a 12-mesh screen. One of the 5-ft. Bryan mills, running at half speed, takes all the coarse

sand, from 10 stamps (approximately 20 tons per day), and crushes it through a No. 9 slotted screen, equivalent to 40 mesh. The final product from the Bryan is passed over two 6-ft. Frue vanners and two 6-ft. Triumph tables. From these concentrators the pulp is raised by two 54-in. Frenier sand-pumps to two sets of cone classifiers. This system is a modification of that introduced by Mr. Merrill at the Homestake cyanide plants. The top cone takes the intermittent discharge from the sand-pump and is so adjusted by valves that it sends a fairly uniform flow of pulp to the two smaller cones. The top cone is not a

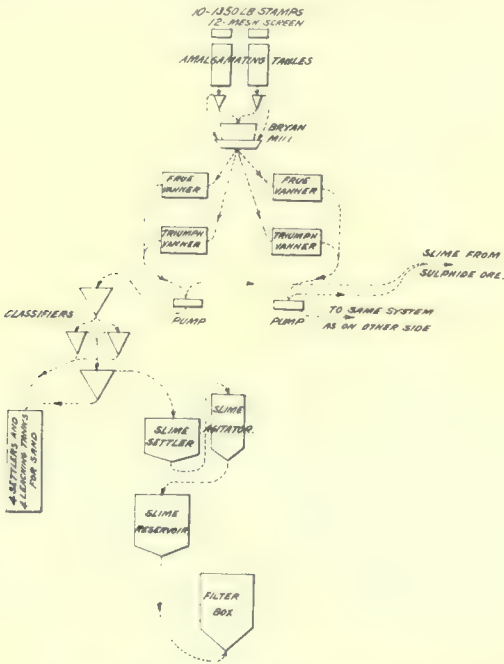

Fig. 1.—Treatment of Oxidized Ore.

good (over 95%) since the introduction of the Butters-Cassel filter. A contemplated re-arrangement of the cones is expected to improve the extraction from slime. In a small mill, classification requires constant attention. Slight interruptions, the suspension of one battery unit, or any variation from normal operating conditions, at once affect the flow of pulp in the classifiers, which are dependent upon nice adjustment for their efficiency. Obviously, the larger the mill, the smoother will be the operation of this system, and the less attention will it require.

From the cones, the sand flows to a pipe distributor and thence to a settling vat, of which there are four on each side of the mill. The fourth vat was added after the completion of the mill. These vats were at first provided with an overflow lip and a circular launder to carry off the surplus water. It was found, however, that occasional irregularities in classification resulted in the settlement of slime in these vats, which interfered with

Fig. 2.—Cross-Section of Amalgamation Table.

classifier. The first rough classification is made in the small hydraulic cones, from which a stream of sand flows direct to the sand vats. The overflow from these small cones, consisting of slime and fine sand, flows to the larger lower cone, where a closer classification is made.

percolation. The settlers were then fitted with slime-gates, and the overflow from the sand-settlers, carrying a certain amount of slime, now runs to a centrifugal pump at the lower end of the mill, to be sent to the slime-settlers for clarification. This is an awkward

Fig. 3.—Movable Amalgamation Table Used in the Combination Mill.

The stream from the bottom of the latter also flows to the leaching vats. The overflow from this large lower cone passes to the slime settlers.

The pulp from the Bryan mill may, therefore, be said to consist of two products, namely:

1. Sand

Retained on 100 mesh.....41%

Passing 100, retained on 200...35%

Passing 200 mesh.....24%

67% of total.
2. Slime...

Passing 200 mesh.....90%

33% of total.

This is not considered an ideal separation, inasmuch as the slime carries a large amount of fine sand. In spite of this, however, the recovery from the slime has been very

arrangement, but was unavoidable owing to the small gradient of the millsite.

When the sand settler is filled, the surplus moisture is removed by a Gould vacuum pump, and the charge shoveled to the treatment vat below. Here the charge is given an eight days' treatment with a 0.1% and a 0.2% cyanide solution, and the residue discharged by sluicing through a central bottom-discharge door.

The slime is delivered to the centre of a conical-bottom settler, provided with a rim overflow. There are two of these settlers on each side of the mill. Each is alternately allowed to fill and overflow for 12 hours, and allowed 12

hours for settling. A pipe decanter carries off the surplus water, leaving the slime with about 50% moisture. Sufficient strong cyanide solution is added to the charge of slime to make a solution of from 0.15 to 0.2% cyanide, and to give the pulp a consistency of three parts solution to one of slime. By means of a centrifugal pump, the pulp is transferred to an agitator, with a steep cone-bottom. By means of valves, the same machine (a 3-in. Krogh slime-pump) is applied to the agitation, taking the slime from the bottom of the vat and throwing it back at the top. A supplementary agitation is given by means of a mechanical stirrer revolving slowly. The pulp and stirrer give an ideal agitation, being sufficiently complete for the best results. The pump, which has a lift of about 10 ft., is run at 375 rev. per min. Thus, at short intervals, the whole content of the vat passes through the pump, where it is aerated by means of a pet-cock on the suction pipe. The stirrer prevents the settlement of fine sand at the junction of the cone bottom with the staves, and keeps up the agitation during pump repairs. The only repair required in the pump is the replacement of the shaft about once per month. The objection urged against the centrifugal pump as an agitator—that it is apt to clog with slime during stoppages—is not a sound one. The 'slime' product at the Combination mill carries a large amount of fine sand, and the pump has repeatedly been started up after stoppages of several hours, without the least trouble.

After agitation, lasting from 12 to 18 hours, the pulp is discharged into a slime reservoir, a vat of large capacity provided with a mechanical stirrer from which it is drawn, as required, for filtration in the Butters-Cassel filter.

A filter-press was at first used for filtering the slime. This was an American machine consisting of fifty 42-in. plates and 2-in. distance frames, and had a capacity of 2½ tons of (dry) slime. It was evidently made of poor material, as it was the source of exasperating trouble through breakage. The plates were continually cracking under a pressure much below the guaranteed maximum, and the outlet-cocks getting out of order or breaking. Moreover, the operation of pressing, washing, and discharging was extremely slow, requiring about five hours, and the operating expense high, requiring two men on each of the three shifts at the prevailing laborer's wage of \$4 per day, to say nothing of the cost of filter-cloths. It is fair to suppose that one of the high-class foreign presses of the Dehné type might have given better satisfaction. At best, however, filter-pressing is not to be compared with the system now in use, especially as regards cost of operating, and the completeness of the washing operation.

The essential points of difference between the Butters modification of the Cassel filter and the other vacuum-filtering schemes are the extreme simplicity in the design of the filter-leaf or frame, and the fact that these frames, throughout the operation, are always stationary. In the Combination plant there are 28 frames (5 by 10 ft.) set 4½ in. apart in a box 10 ft. square with a pointed bottom inclined at an angle of 50°. The slime-pulp is introduced at the point of the box, and a vacuum of 22 in. of mercury is maintained for about 20 min., during which time a cake is deposited on each side of the frame ¾ to 1 in. thick. The surplus pulp is then withdrawn to the slime reservoir and the wash introduced, consisting of a weak solution of cyanide. When the cakes are thoroughly washed, the weak solution is withdrawn into its proper vat, and water introduced, until the frames are completely immersed. The object of this final water is to assist in removing the cakes. More water is introduced into the interior of the frames under a low head. This

causes the cakes to drop off clean, into the pointed bottom of the filter-box, whence they are finally removed by sluicing. The whole operation requires about 3½ hours, and about nine tons (dry) slime are treated at each charge. The plant, therefore, has a capacity of about 63 tons per day. It is operated by one man on each shift. The principal power required is for pumping the pulp and the various solutions in and out of the filter-box, and for operating the vacuum pump. In addition, the gold-bearing solution discharged from the vacuum pump is raised about 30 ft. and forced through the discarded filter-press now used for clarifying purposes. The whole consumes about 10 h.p. A 15-h.p. motor has been installed for this work, but has extra work to do not connected immediately with filtering.

The filter-plant has required no repairs since it was first operated in February of this year, and has worked in the most satisfactory manner. The cost of filtering (exclusive of power) has been reduced from 96c. per ton

Fig. 4.—Treatment of Sulphide Ore.

of slime in January (using filter-press) to 26c. in May (using the Butters system). The power consumption appears to be about the same in the two processes.

Treatment of Sulphide Ore.—This ore is crushed to 12 mesh in two 5-stamp batteries, and run over plates to take up the small quantity of free gold present. See Fig. 4. A classifier at the end of the plate-tray removes the coarse sand and sulphide, which go to a Wilfley concentrator; the overflow of slime and fine sand passing to the outer lip of a Bryan mill. One Wilfley table, therefore, removes the coarse sulphide from the product of ten stamps crushing to 12 mesh. The tailing from the Wilfley is raised in a bucket-elevator to a Bryan mill, which crushes it to 40 mesh (No. 9 slotted screen). The tailing from the Bryan mill joins the stream of slime from the small classifier and passes to four 6-ft. Frue vanners. Here a large quantity of fine sulphide is removed. The Frue tailing is then elevated by a sand-pump to a classifier above a 4 by 12 ft. Abbé tube-mill of the trunnion type. The cone acts as a classifier as well as a de-watering device. The coarse sand passes to the tube-mill; the slime overflow joins the tailing from the tube-mill and goes to three Wilfley slime-tables of the latest pattern. The tailing from the last, consisting of slime and fine sand, is elevated to the cone-classifiers in the original mill, where it is mixed with the oxidized tailing and treated in the cyanide plant.

This plant was only operated a few days, and then shut down pending the installation of two Wilfley slime-tables, making three in all, the first having been set up experimentally. During this short run the results were very promising. Of the final product from the slime-table, 87% passed through 200 mesh, and the three stages of reduction showed a saving by concentration of over 80% of the contained gold. With the cyanide treatment of the slime tailing, a confirmation of the small mill-run is expected—namely, better than 90% recovery.

It is too soon to give the results of tube-mill work. The

mill is lined with 2½-in. sillex blocks, which will be replaced by blocks 4 in. thick.

Precipitation is accomplished in the usual way by means of zinc shaving. The solutions are richer than are usually seen in cyanide mills, reaching as high as one ounce per ton in gold. Owing to the absence of silver, which undoubtedly facilitates the precipitation of gold, a very large zinc surface is required. The precipitate is refined with sulphuric acid and smelted in a pot-furnace, with gasoline, a powerful jet being maintained by means of a small upright Leyner compressor.

The following details of costs for milling and cyaniding indicate a few of the difficulties met with in an isolated district where the cost of supplies, and of labor, power, and water are unusually high. And then it must be borne in mind that the mill is of small capacity. The change from steam to electric power—the latter being furnished by a local concern operating a 90-mile transmission line—reduced the cost of power from a maximum

of \$1.73 per ton (January, 1906) to \$0.76 (May, 1906). We have already noted the great reduction in cost effected by introducing a new filtering system for slime. The marked decrease in operating expense during February was due to increasing the capacity of the mill by annexing ten stamps, making twenty in all. While the total milling and cyaniding cost of \$5.828 per ton seems high, it is really not so when local conditions are considered. It is expected that further retrenchment will soon cut this down to \$5 per ton.

The recovery in the mill and cyanide plant has attained a maximum of 93% for several consecutive months, and has averaged over 90 per cent.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

ORE-CONCENTRATOR.—No. 829,443; Walter R. Thurston, Douglas, Arizona.

A concentrator comprising a stationary hopper having discharge-openings, a distributor below the hopper for conducting the material discharged from the hopper, an oscillating disk-shaped or concave pan below the distributor for receiving the material from the distributor at points adjacent to the outer edge of the pan, an overflow-pipe for the waste having an inner sleeve passed centrally through the pan, and adjustable vertically within the pan, a stuffing-box on the pan through which the pipe passes, a central shaft for supporting the pan and overflow-pipe, means for oscillating the pan and overflow-pipe about the axis of the shaft, a spout leading from the overflow-pipe, and a valve-controlled discharge-spout leading from the pan at a point exterior, but contiguous to, the overflow-pipe, for the discharge of the concentrate.

METALLURGICAL FURNACE.—No. 829,671; George W. Shear, Joliet, Illinois.

A furnace having its roof formed in part with straight, oppositely-inclined portions, the inclination of one portion being greater than the other, and also formed with a rampant arch, the lines of said arch merging with the lines of the straight portions, and the inclination of the arch being toward the front of the furnace.

PROCESS OF SOLIDIFYING EARTHY GROUND.—No. 829,664; Herman Mehner, Friedenau, near Berlin, Germany.

Process of solidifying earthy ground consisting in providing means at the borders of the ground portion which it is intended to solidify, adapted to carry away heat from the

said ground portion and introducing into the ground which is to be solidified a mineral substance in liquid condition adapted to become solid on cooling.

DEVICE FOR REMOVING ORE-SLIMES FROM SETTLING-TANKS.—No. 829,516; Henry Earle, Denver, Colorado.

In a device for removing ore-slimes from settling-tanks, the combination with the settling-tank of a flexible tube connected with the discharge-pipe, one or more pairs of rollers for grasping and compressing said tube and means for moving said rollers downward and returning them to the point of beginning.

ROASTING FURNACE.—No. 827,226; Herbert W. Fox, Colorado Springs, Colorado.

The combination with the furnace having metallic portions, and rabble-shafts passing through the same and a chamber X, of a fireplace at the side thereof, a flue leading from the fireplace to the top of the furnace, and injectors arranged to project jets of air, or air and steam transversely of the said flue.

ELECTROSTATIC SEPARATOR.—No. 827,770; Milard Woodsome, Boston, Massachusetts.

In an electrostatic separator, combination of a repelling-electrode, means to feed material thereto, an opposed electrode, electrical exciting mechanism and connections therefrom to the electrodes, and an electrically-conducting shield surrounding portions of the repelling-electrode which are

not in immediate opposition to the opposed electrode, said shield being electrically connected with the exciting apparatus in parallel with the repelling-electrode.

An Old Firm in New Quarters.

On September 11, the Joshua Hendy Machine Works, after having been incorporated since 1882, was merged into a new corporation, known as Joshua Hendy Iron Works. Articles of incorporation were filed on that day, the subscribers all being the present directors of the Joshua Hendy Machine Works; therefore the old company, despite the disaster of April 18, 1906, finds itself with an increased capital stock of \$1,000,000 wherewith to continue its business operations. On the old site at 75 Fremont St., there is being erected a two-story building, 91½ by 137½ ft., a permanent structure to house the offices and salesrooms. This will be the first permanent building erected in that part of the burned district.

The temporary offices and shops on the old site at Bay, Kearny, and Francisco St., is to be abandoned on December 1. The manufacture of machinery will proceed

been modeled after one of the station houses used by the Santa Fe railway along its San Joaquin division, and is constructed of re-enforced concrete, two stories high, 120 ft. long, and 40 ft. wide, the upper story of which will be used to house the engineering and drafting departments of the company. The buildings are arranged in a quadrangle. The machinery is all new, the previous equipment of the company having been totally destroyed in the fire; every machine will be operated directly and independently by electricity. It is estimated that the buildings will cover about ten acres, thus giving the community another large machine-manufacturing plant on this Coast, and one of the largest devoted exclusively to the manufacture of mining machinery.

Trade Treatises.

THE HENDRIE & BOLTHOFF MANUFACTURING & SUPPLY CO., of Denver, Colo., has issued a pamphlet describing

The Joshua Hendy Iron Works.

in the new works nearing completion at Sunnyvale, in Santa Clara county. The company recently acquired a large tract of land at a place formerly known to old Californians as Murphy's Station, now called Sunnyvale, about ten miles north of San Jose on the coast line of the Southern Pacific railroad.

The accompanying illustration is taken from the architect's drawings of the proposed plant. There has been some delay in securing material for the completion of these works, but this obstacle has been overcome and the work is rapidly nearing completion.

The machine-shop is 420 ft. long and 80 ft. wide. Two 50-ton Niles traveling cranes, electrically operated, will handle the machinery in this department. The foundry building is 300 ft. long and 60 ft. wide, with a daily cupola capacity of 30 tons. The blacksmith-shop and boiler-shop exceed 200 ft. in length and are about 50 ft. wide; the pattern storage building is a two-story brick structure of fire-proof construction; nearly adjoining it are the carpenter and pattern shops; the offices or administration building has

the Jelinek cage-chair, a cage equipment increasing the speed and safety of hoisting through shafts.

THE WESTINGHOUSE ELECTRIC CO. has issued a finely illustrated pamphlet, descriptive of the lighting of various large public buildings, by means of the newest lamp.

THE BLAISDELL CO., of Los Angeles, Cal., sends a well illustrated booklet describing the system of automatic cyaniding machinery for which this company has won a deserved reputation.

THE SCIENTIFIC INSTRUMENT CO., LTD., Cambridge, England, has issued a comprehensive publication (List No. 39), on technical methods of heat measurement. The work is entitled 'Technical Thermometry.' It describes numerous instruments for measuring heat and heat radiation.

ALLIS-CHALMERS CO., Chicago, Ill., issues an interesting illustrated Catalogue No. 17, on mining and quarry cars, skips, and buckets. Catalogue No. 10 describes Huntington mills and the methods of assembling them. Bulletin No. 1507, besides detailing Allis-Chalmers air-compressors, gives interesting notes on the theory of compression.

Editorial.

THE ARTICLE on the Salton Sink under the title of 'A New Inland Sea' will prove interesting to those who have taken note of the vagaries of the Colorado river. The relief map of the Reclamation Service tells its own story well. In the current issue of *Out West*, there is an excellent article on the same subject by Mr. Sharlot M. Hall, which describes the agricultural conquest of the desert that is traversed by the Rio Colorado.

THE VICTORIA QUARTZ mine at Bendigo is down 4,300 feet, and much interest is taken in Australia in the ventilation of the bottom workings. Despite the fact that the water issuing from the rock has a temperature of 115° F., the air at the bottom of the shaft registers 86° only. Owing to the close vicinity of other deep shafts and communicating workings, it has been possible to establish an excellent system of natural ventilation.

TWO BIG PROBLEMS before the manufacturers of steel are how to prevent corrosion of structural material and failure of rails when in service. It has become evident that it is the maker of the steel, and not the manufacturer of the paint that protects its exterior, to whom the engineer must look for such improvement as will prolong the life of the material he uses. So many comparatively rare earths have been found to toughen steel and to give it better resisting qualities that it does not seem too much to hope that the addition of one of these may increase its ability to withstand corrosion.

JUST AT the time when the national ownership of railroads is being discussed in the United States, the Americanization or competitive joint-stock ownership of the railways of South Africa is being advocated in the Transvaal. The State-owned railways of that great gold-mining region are considered as giving a most unsatisfactory service with exorbitant rates. One man's food is evidently another's poison. In South Africa the effort to earn profits from railroads that traverse a sparsely populated country, the industrial growth of which has not progressed far, necessitates high rates of transport, against which the mining communities have protested under the Boer regime and under British rule.

COPPER is selling for over 20 cents per pound. What this means to those mines which have generous lodes and economical management can be gauged by the fact that at the Wolverine mine during the last financial year it cost 6½ cents per pound to mine, mill, and market the copper produced. The Calumet & Hecla produces its copper for a cost of 8 cents per pound, and there are several mines, managed skillfully and operated on a large scale, that work for less than 10 cents per pound. Two years ago conservative estimates of future profit were based on an

average price of 13 cents; a mine that made any sort of profit then is in bonanza now. With copper above 20 cents, lead at 5.75, spelter at 6.06 cents per pound, and silver at 69 cents per ounce, the metal market presents an aspect encouraging to the miner. Civilization moves forward on iron rails and over steel bridges, it is sheathed in copper and adorned with silver, it needs spelter for its melting moments and lead to preserve its gravity, it talks either over copper or aluminum and its hard heart is gold; it needs the metals in every department of its multifarious activities. The age of wood and stone in construction and engineering is passing with the horse-car and the sailing ship. There is an increasing demand for the ore that comes from a hole in the ground, and there is a place for all the metal that the miner produces.

Reports on Mines.

Our contemporary at New York recently published some sensible remarks on reports of mine examinations, and, in the main, we agree with the tenor of them. To one suggestion we demur, and that is the idea of a decadence in the character of such documents. Of course, there are many reports that fail of their purpose, which is to convey the information necessary for the valuation of a mine, but, on the whole, as we remember the character of the stuff that passed current twenty years ago, we feel inclined to emphasize the great progress made in this branch of engineering practice. For it is an essential part of the engineer's work. What is the use of careful investigation, accurate measurement, and logical reasoning if the result of it all cannot be expressed clearly, to the end that the information can be conveyed from the intelligence of one man to that of another in the furtherance of business? There has been a notable advance in this respect. The time was when a report made by a representative mining engineer would include a general description of the mine and its environment, a story of its life, a record of its production, a few maps and the results of assays made on a scattering of grab samples or specimens; this being followed by estimates based wholly on the assumption that the ore in the mine was as good as that which had come out of it, and that therefore the yield during the future could either be maintained or doubled at will by enlarging the reduction works. Today the humor of such reporting would be recognized; it would never be taken seriously. It is true, the offices of exploration companies and similar organizations engaged in legitimate mine promotion are inundated with a mass of reports, most of which are open to criticism on account of their wordiness, incompleteness, or obscurity. But this is due, not so much to the general decadence or essential insufficiency of mine reporting, as to the multitude of men who perform such work nowadays. The number of men capable of appraising a mine has been multiplied immensely by reason of the spread of education and the facility for gaining experience; the financial activity directed to mining enterprises is twenty times greater than it was twenty years ago, and the variety of people engaged has grown in proportion. Formerly only edu-

cated engineers wrote reports; nowadays all sorts and conditions of men are allowed to have their say: Prospectors, geologists, metallurgists, and promoters, as to whom one can say that each has his function in the mining economy, but the appraisal of a mine is not the particular one for which they have been trained. Yet any one of them may by experience, sometimes at the expense of clients, become particularly well qualified for the work. A few prospectors possess an instinct tempered by judgment, so that their opinion is worth money; a few geologists learn enough about minesampling to check their constructive imagination; a few metallurgists have added thorough knowledge of mining to their own special training; and of the promoters we find two classes, those who have graduated from mining into finance, and those who—to aid their finance—have taken pains to learn something about mining. From each of these classes of men there is recruited a number of energetic nomads who write reports, and it is but fair to say that the average of them comes nearer to the essential facts than did the clumsy document prepared by the mining engineer of an earlier day. Therefore we take a cheerful view; we believe that the first-rate mining engineer of today, by reason of the improvement of method due to world-wide industry and intense competition, does incomparably better work than those of aforetime, and that after him the irregulars, the volunteers, and even the camp followers do as well as the academic regulars of a day when the mining horizon was narrow and the industry provincial.

Patents.

Anyone scanning the Official Gazette of the United States Patent Office will find much interesting information, which is not quite submerged beneath queer spelling and rudimentary grammar. This record of the inventive minds of the country is eloquent of the multifarious channels into which its energies are directed. Apparently drinking is an important function of our people, for the non-refillable bottle is the elusive goal of so many ingenious people and next to it comes its complement the bottle-stopper. The importance of railroad operations is reflected on the pages of the Gazette, for nut-locks, automatic switches, car-couplings, and signaling apparatus are invented every month. The farmer is in the mind of the inventors who take out patents for disc-harrows and self-closing gates. While the art of printing and the multiplication of writings has progressed rapidly, there is hope of further advance, for printing devices and typewriting machines are commonly found among the new patents. Toys bespeak a love for the little ones and it is satisfactory to observe that the amusement of children should be regarded as a profitable business. Finally, the childlike in man is expressed in the many garment supporters, clothes-presses, and hat-hangers which are designed each month. It argues at least a regard for neatness, to which cleanliness is allied, and a growth of taste in one of the small, but salient features, of the manner of living usually termed civilization.

By the Way.

In an address delivered by Mr. Walter C. Kerr to the graduating class at the Staten Island Academy, he said:

The only objection I have to commencements, whether of academies or colleges, is the intimation that they are the end of education and the beginning of the world. Education is a continuous performance, the first acts of which are within halls where systematic guiding gives direction and method to personal endeavor. One reason why many who have had much schooling are poorly educated is that they stopped learning, and by a strange anomaly they seemed to stop at commencement.

The education you get through books and teachers is elementary. That which you gain yourself may be profound. Profundity is wholly a matter of quality, not quantity. The world is too full of a number of things, and you will find more tendency to scatter than to concentrate. It is therefore well to do whatever you do with all your might and regard nothing as too small to be done the best you know how. Cleverness will not accomplish much. Brilliancy only serves to permanently polish good things and temporarily polish bad ones. Grace and culture lend charm to anything, but none of these things make for progress. Advancement only comes through good, hard work, diligent application, faithful performance, correctness, accuracy, and that fine display of judgment which flows only from a well ordered mind, capable of thinking independently, acting resolutely, and fearing nothing.

At this commencement time it is well to commence to forget the standards set by the completion of printed pages and the measure fixed by examinations. The world's problems do not come systematically and in the preferred order of easy ones first, followed by a gradation to the most difficult. They come by chance and they hit you sidewise, endwise, and with all degrees of percussion. You must meet them, solve them, get good out of them, and utilize them as the means to further achievement.

Some persons devote much time to passing opinions, stating what they think. It does not make much difference what you think about things. It is what you do about them. There is even danger of thinking too much unless thought is intuitively coupled with action. Your thoughts may sometimes wander harmlessly, but your acts need be right all the time. If you can now begin with the elementary education you have received in a good academy, or even the more extended but still elementary education which some of you will receive in college, you can proceed to make your personality effective in doing those things which your natural tendencies lead you to best do. You will then, in the course of perhaps twenty or more years, become fairly educated as measured by the standard of human performance related to the average span of life.

Humanity is composed of all kinds of people possessing widely different temperaments, tastes, and abilities. It is well that they are not all alike. Anyone will achieve the greatest effectiveness through the opportunities and training which develop native powers. Any other training is liable to stunt the natural growth. Variation in progressive development should be in the direction in which one tends to vary. This assists in the survival of the fittest, the survival of the unlike, the survival of the effective.

Manifestly there must be as many kinds of education as there are types of people, and fortunately the number is not so great but that they can be readily supplied at least within our higher institutions. So long as education was confined to one channel, those whom the

channel precisely fitted were greatly benefited; those whom the channel somewhat fitted were somewhat benefited; those to whom the channel was a misfit were injured because, during the formative period of their development, their native power to vary was resisted, their minds forced away from their natural trend, and energies which could have been potent for good in certain directions were dwarfed by the compulsory exertion of uninteresting, unproductive effort. This results in a kind of mediocrity which is stagnation. You can't make anything good of a man except to make him better in that which he is. You can't unmake him and make him over again.

If it be held that one must needs have the so-called liberal education in order to be well rounded, it is pertinent first to determine whether roundness is what is really wanted and the fitness of the subject to the end. We don't build walls of round stones. We hew them square—some are better rough hewn and others are better when polished. It is not well to attempt to take all the corners off humanity. They should be left on to dent something.

When it is observed that in our modern universities which offer to students wide ranges of educational courses, less than one-quarter follow classical pursuits when left to free choice and that over three-quarters elect professional and industrial education, there is good reason to believe that this is about the proportion in which minds are fitted to receive benefit from the acquirement of the respective classes of knowledge and training. I therefore maintain that instead of decadence in the humanities they are elevated by this natural selection because their representatives become only those whose minds are fitted to take such education and who will therefore conspicuously represent the best possibilities of classical training applied to those to whom it is adapted.

In addition to the several agreeable and desirable attributes of classical training, its fundamental benefit comes through the melting down and re-casting of thought, which to some minds is a stimulating and cultivating process. There are other processes of like kind and quality that are adapted to other minds, notably the melting down of the laws of nature and re-casting them as applied science. Another cultivating and most useful process, too little practiced, is the melting down of one's own thoughts and so re-casting them that they can be understood.

We have heard too much about knowledge for its own sake *versus* knowledge for use. All knowledge is for use. All education is for action. The engineer uses mechanics and thermo-dynamics in a certain direct way. The architect uses art and constructive knowledge in a similar way. The lawyer uses his knowledge in a less material way. The classical or philosophical man uses his acquirements in a different way, but if he does not use them they are useless. The older I grow the more I think there is no such thing as liberal education, liberal arts, or liberal anything, as distinct from specialized departments of knowledge. As to the so-called specialized courses, these are only names. They are no more special than the humanities. Some are scarcely so highly specialized. All education is liberal or all is technical, according to our definitions, but all is for use.

To youth this old world is always a new country. Pioneers must plunge in, turn over what to them is new soil, and make of it the best they can; always in the spirit of industry and honesty, with that aspiration for betterment which invariably turns for good that which is worthy and turns to naught that which is undesirable.

The fault and the fate of the rolling stone is not so much because it rolls as it is that it usually rolls down hill. When you move be sure of your direction.

Johannesburg, Transvaal.

Less Crime Among the Chinese.—Better Police Supervision.—Reading Rooms for Miners.—Increased Gold Production.—The Premier Diamond Mine.

There has been a most acceptable diminution of Chinese crime along the Rand. One got so tired of picking up the morning paper and reading of 'Another Chinese Horror,' that it is quite a relief to find this head-line of yellow journalism missing from the daily paper. Every offence committed by a Chinaman has been magnified far more than if the wrong-doing were done by a Kaffir or white man. One feels sorry for the anti-Chinese brigade, whose chief topic of conversation—'Chinese outrages'—is being taken away from them. One reason for the improved state of things is the gradual re-patriation of the undesirable Chinese. The Protector of Chinese has the power under the ordinance to send back to China any coolie that is considered a dangerous character. Another reason is the improved police supervision, and more earnestness on the part of the authorities to make the punishment fit the crime. At one time a coolie had no objection to spending a month or two in jail; in fact, he looked upon his sojourn there as a holiday. But a coolie does not look forward to a month's residence in jail with much pleasure now. A very good scheme has been put into operation by the Foreign Labor Department. Periodically, they send out a Chinese notice to the mines, written in all the flowery language of the East, informing the coolies of those of their compatriots who are undergoing long imprisonment for serious crimes, and of those that have been hung for murder. These notices have an excellent influence in the compounds.

There has been considerable improvement on the mines in the way of provision of recreation for the men during the last few years. Spacious recreation clubs have been built at nearly every mine, where the men can spend their spare time, instead of sitting in cheerless rooms. In each club-house there is a large billiard room, with two or more tables. There is also a large assembly hall, with a fine stage, where theatricals and concerts can be held. Each mine has a library and reading room, and efforts are being made to induce the men to read technical literature, and pay less attention to books, of the 'blood and thunder' type. The employees of the company are charged from \$0.75 to \$1 per month subscription to the club. Billiards cost the men less than half what is charged at the bars in the neighborhood. It is difficult to decide exactly how much a hall saves the company, but the indirect advantage is very great. On some mines the improvement in sobriety has been marked. The men do not run away from the mines at week ends, but remain on the properties and spend their time at the club. Altogether the introduction of these halls has proved a great success.

The results for August are not yet published, but there seems to be little doubt but that another record will be established. It is satisfactory to note that the struggling companies, like the New Unified, which were recording losses a few months ago, are now earning fair profits; in fact, there is scarcely a producing mine on the Rand that is not making a small profit. This speaks volumes for the great gold deposit, which is being worked for a distance along the strike of more than 60 miles.

There has been some comment upon the drop in grade at the Premier diamond mine. In January 1905 the returns were 0.77 carat per load, while for August 1906 it was only 0.25 carat per load. The scale of operations has increased from 99,933 loads washed in January 1905,

to 411,707 loads washed in August 1906. In spite of the fall in grade, the Premier is still the greatest diamond mine in the world.

Joplin, Missouri.

The Weekly Returns.—Record Output Expected for 1906.—New Companies Organized.—Important Discoveries Made by Drilling.

The highest price reported for zinc ore last week was \$47 per ton, one carload selling at that price from the Missouri Lead & Zinc Co.'s land. Lead ore remains steady at \$82.50 per ton and shows much firmness. The shipment of zinc ore from this district shows an increase of 653,380 lb. over the previous week, and 1,964,840 lb. more than the same week last year. The lead ore shipment was 290,480 lb. less than the previous week, but 651,680 lb. more than the same week last year, and the value was greater last week than that of the previous week by \$1,090, and more than the same week last year by \$59,103. Zinc ore sold a year ago at \$55 per ton and lead ore at \$63.50 per ton. The ore shipments for the week were: Zinc ore, 11,600,560 lb., valued at \$242,660; lead ore, 1,771,430 lb., valued at \$70,523; combined value, \$313,183. The shipments for the 39 weeks of this year are: Zinc ore, 413,515,660 lb., valued at \$8,956,394; lead ore, 58,298,650 lb., valued at \$2,233,320; combined value, \$11,189,714. The shipments for the same period last year were: Zinc ore, 376,387,780 lb., valued at \$8,425,585; lead ore, 46,371,350 lb., valued at \$1,358,540; combined value, \$9,784,125. Should the weather remain favorable for the next three months the value for the year 1906 should reach the \$15,000,000 mark, making it the best year in the history of this mining district.

Articles of association have been filed by the Rhea Lead & Zinc Co., with 350 shares of the value of \$100 each, all paid up for a term of 20 years.—The Overland Lead & Zinc Co., of Webb City, has been organized, with 120 shares of the value of \$250 each, all paid up for a term of 50 years.—A company composed of Jess Harrison, Wm. McAboy, W. N. Johnson, Jerry Clark, and George Booth, all of Webb City, made a rich drill-strike in Newton county, two miles west of Diamond, recently, encountering the ore at 65 ft., and they are still in it at 110 ft. The drillings show this to be one of the best strikes made in that locality. Other holes will be put down and the land thoroughly tested.

The Little Pearl Mining Co., under the management of T. C. Malloy, which has a lease on 14 lots on the Continental tract, promises to open up one of the best mining propositions in this part of the district. In a drill-hole now being put down near the centre of the lease, the company has encountered what is thought to be the richest run of ore ever found on the Continental tract. At a depth of 50 ft. a run of lead ore was found and continued down to 70 ft. At the 85-ft. level zinc ore was found and continued down to 165 ft. At this depth the drill-tools became fastened, but as soon as they can be loosened the hole will be put down to a depth of 200 ft., where the run of sheet ore now being worked by neighboring companies ought to be found. A shaft is being sunk near the drill-hole and is now down 20 ft. In a shaft a couple of hundred feet east of this last drill-strike, two good faces of ore have been opened up at the 145-ft. level. A new 200-ton concentrating plant is to be built. More drilling will be done on the lease to thoroughly test the land.—William Houk, who recently opened up a splendid mine on the Granby Mining & Smelting Co.'s land at Smelter hill, now has the property in shape for making regular returns. After taking the lease on this tract and before commencing permanent development work, Mr. Houk put down 27 drill-holes, good runs of both lead and zinc ores being found in 22 of them.

London.

South Crofty Meeting.—*East Pool Yields Profits.*—*Cornish Consolidated Tin Mines Acquire Lease in Botallack District.*—*Great Cobar Monthly Profit Exceeds £15,000.*—*Scheme to Develop Enormous Hematite Deposits of New Zealand.*—*Changes at Dolores.*—*El Oro Annual Report.*

At the first (statutory) meeting of the shareholders of South Crofty, Ltd., held two weeks ago at Camborne, particulars of progress under the new company were given. The actual management was taken over about the beginning of August, and it early appeared that attention would have to be concentrated upon the prompt completion of Robinson's shaft. Until that shaft was equipped and completed economical working could not well be introduced. Up to the present they were at the 170-fm. level. They had a station at the 60-fm. level for a balance box, a cistern plat had been cut at the 170-fm. level, and a tram-road also had been made. A good deal of dead work naturally had to be carried out in removing more than 700 tons of rock. The pit work in itself was only carried to the 36-fm. level below the adit, and now it had to be completed to the 170. The tenders for the necessary pit work were out, and the work itself should be delivered at the end of October; but the timbering and pit work made a heavy job, and would take some time to do. In the meantime, from the bottom of the shaft they had brought to the surface

Sketch Map Showing Position of Joplin.

six tons of ore from a lode six feet wide, and those six tons carried 37 lb. mineral per ton, which was exceedingly satisfactory. At present their ore carried a little over 7% wolfram, and their intention was to eliminate that wolfram and send clean tin to the market, so that it would fetch as good a price as that of anybody else. The price of the magnetic separator was already settled, and the machine would be delivered in five weeks. At the present moment they had on the floors 35 tons of tin from the stopes, and they had only been using 32 heads of stamps out of the 60, the remaining 28 having been pulled out to be replaced by more modern stamps. When they took possession the mine was selling at the ticketing a little over eight tons per fortnight, and at that time they were employing 80 men in the stopes. Fifty-five men were wanted for the dead work, which only left 25 stoping. On the other hand, although they only had 32 heads of stamps running, they managed to keep up to three tons of tin per week, which nearly covered all the cost of mining and dead work, and they were drawing on their capital only to the extent of £100 per week. The intention with regard to the future was to deal with 100 tons per day, and the ultimate crushing capacity would be to the extent of 40 head of Californian stamps, with a weight of 1,050 lb. per head, and probably they would bring up the duty of each stamp to three tons per day.

The ore that had gone to the stamps during the past month had yielded 40 lb. of mineral per ton, which spoke well for the mine. With regard to the royalties they had approached the landlord and the royalties had been reduced to one-twenty-fifth when black tin was over £80, and one-thirtieth when it was below that price, which might be considered very reasonable terms. C. Fred. Thomas, general manager, told the meeting that his first impression of the mine was distinctly a favorable one; but they had to deal with complex ore. For instance, at the 160-fm. level, west of Robinson's shaft, it was not an unusual thing to take up a stone in which could be easily distinguished tin, arsenic, wolfram, and copper. The statement of accounts of the East Pool and Agar United mines, adjoining South Crofty, shows a profit of £4,368 on East Pool section, and a loss of £24 on Agar, the profit being considerably less than for the preceding

Transvaal and Surrounding Country.

twelve weeks. The agents report that in the early part of the year the tribute pitches fell off in value, and have not yet recovered. They say that the cutting of the new South lode at the 170-fm. level is an important feature in connection with the mines, as it will add considerably to the output and life of the property. Development work has increased during the year, and will be still increased in the coming year. Tin stuff mined during the twelve weeks amounted to 13,454 tons (dry weight); levels, cross-cuts, winzes, and raises, 110 fm. 3 ft. 9 in. About £5,800 was received for by-products. The Cornish Consolidated Tin Mines, Ltd., says the *Western Daily Mercury*, has acquired a lease of Botallack, Carn North, and Buzza, adjoining setts, and intend to work the three as one concern. Buzza was formerly a part of Wheal Owles, but is distinct from the part holed into Boscean thirteen years ago, when several men were drowned. The company named, of which F. Allen is chairman, is already working Clitters, Ltd., and has a large interest in South Crofty. When Botallack ceased working, the miners had followed a rich lode a long way under the sea, and the intention of the new company is to work the lode vigorously. The mine will also be sunk deeper probably by means of a new perpendicular shaft. Nothing has been done below the 200 level, while the adjoining Levant mine, a steady producer, is down 360 fathoms.

Botalack has first to be unwatered, but a portion of the scheme provides for this. All the money necessary has been guaranteed, and the public will be shortly given the opportunity of subscribing a portion. The mine ceased operations in 1895. In the last five years' working there were sold 376 tons of tin per year, at an average price of £49 per ton. The working costs were £54 per ton, and the loss about £9,000. If the same quantity of tin were sold each year at the present price, and the working costs per ton were the same, there would be a profit of £90,000 in five years. W. Thomas, for over 20 years instructor in mining at the Camborne School of Mines, who is now in charge of King Edward, the model mine run by the school, has been appointed manager of Botalack, and will commence his duties next month. The average price per ton of black tin sold at the last Cornish ticketing was £106 8s.—nearly £1 in advance of the previous price; 228½ tons (an appreciable increase on the previous sale) were sold for £24,312 11s. 3d. Dolcoath headed the list, of course, with 65 tons, but the best average price was obtained by Clitters. A correspondent remarks that when the present Dolcoath company started, in 1895, the produce per ton of ore was 79.19 lb. Today it is 41.28 lb., so that hundreds of tons more of stuff have to be taken to the stamps and treated throughout the dressing floors to get the same amount of black tin. It is therefore found that, whereas 28,717 tons of tin ore crushed in the first half-year of the Dolcoath company's operations produced 1,015 tons of black tin, 21,217 more tons of stuff were crushed during the first half of 1906 to produce 95 tons less of black tin. To the splendid price of tin this year must be attributed much of the success now being achieved by the Cornish mines. Dolcoath received on an average £39 3s. 5d. per ton for black tin during the opening half-year of the company's existence, and during the half-year ended June 30, £105 13s. 4d. Fortunately, R. Arthur Thomas has been able to lower the working costs, and there is every prospect of the percentage of produce increasing. Judging from local comments on the labor question it would appear that the hopes expressed at the commencement of the revival, that Cornishmen would return in big numbers from foreign fields, have not been realized, and the necessity for concerted action on the part of the executives grows greater every day. The results of the experiments made in London with the Mackillop high-speed stamps have excited some attention. It is stated that the push cam to accelerate the fall of the stamps was at work in Cornwall several years ago, but failed to get into general use. The entries at the Camborne School of Mines this year are reported to be largely in excess of those of last year at the same time; something like 18 more have entered than in September last year. The list comprises students from most of the large public schools.

Great Cobar, Ltd., has begun well as might have been expected from the favorable circumstances which attended its inception. According to a cable from the mine on the 11th of last month 12,200 tons of ore had been raised since August 22, and 11,300 tons had been smelted, the output of matte from which was 820 tons, the profit on that transaction being estimated at about £15,000. That is for 21 days. An enormous increase in this output is expected when once new machinery is set going. That the stock of this company is in capable hands may be judged from the present market price—£4.12.6 per share for the 750,000 £1 shares. Lloyd Copper, also a New South Wales venture, tells a less flattering tale. Formed in 1899 the company has not yet entered the dividend list, and the £1 shares are quoted at about 15s. A cable advises that, owing to exceptionally heavy rain, the roads are rendered impassable, thus necessitating the closing down of the production plant for

a month. Mining, however, will be continued as usual. The developments in the mine are stated to be highly satisfactory, the lode in the No. 3 level east having widened out to six feet of high-grade ore. A profit of £5,000 is announced for September.

It is reported that J. H. Witheford, who for six years represented Auckland city in the New Zealand Parliament, is now in England in furtherance of a scheme to deal with what has been described by experts as a veritable mountain of hematite ore situated at Parapara, Golden Bay. According to a published statement engineers compute the visible quantity at from 100,000,000 to 600,000,000 tons, and analyses after smelting have proved very satisfactory. In the event of a company being formed to acquire the lease and work the ore with a capital of not less than £200,000 (£100,000 to be spent in acquiring lands, erecting buildings, and in providing the necessary plant), the New Zealand Government has promised a bonus of £1 per ton on the first 20,000 tons of marketable iron or steel produced.

The gross receipts for the month of August from Dolores mine are reported as \$34,500 and the profit \$11,500 from 1,100 tons treated in the mill which broke down during the month. The damage has been already repaired. Notwithstanding this low return, it is generally believed that the critical point in the company's affairs is passed, and when once the initial difficulties connected with the milling, transport, and labor supply are surmounted, Dolores will rank as one of the most notable mines of the Republic. According to rumor, apparently on good authority, George A. Schroter, consulting engineer of the Venture Corporation, has been appointed consulting engineer of Dolores Mines Co., in place of John B. Farish and George J. McCarty, who have retired from the position. The report of El Oro Mining & Railway Co., Ltd., for the year ended June 30 last shows a profit of £204,756, to which is added £32,057 brought forward, making a total of £236,814. After making provision for the new 100-stamp mill, general improvements, other matters, and dividends of 2s. 6d. per share during the year, there remained a balance to carry forward of £58,129. A further £5,033 was expended upon the No. 2 mill, and that construction account is now closed. The erection of this mill, and the introduction of electrical power and of improved metallurgical appliances, have resulted in a substantial decrease in the working expenses and an increase in the percentage of precious metals extracted from the ore. The total average cost per ton, including all expenses in Mexico for the year 1906, was \$5.73 (United States currency) per ton, compared with \$6.87 for 1905; and the average gross value extracted from the ore in 1906 was 84.93%, compared with 73.80% for the year preceding. The replacement of steam by electrical power was commenced in February last, and is now practically completed. During the year 234,079 tons of ore were treated, of an average gross value of \$11.28 per ton, of which \$9.58 per ton was recovered. Although development in depth has been retarded owing to necessary repairs to the Somera shaft, good progress has been maintained in other parts of the mine. The development work for the year amounted to 8,870 lin. ft. Mr. Raymond estimates the ore blocked out and ready for extraction on June 30 at 605,205 tons, with average gold content of \$8.35 per ton. The silver content is about three ounces in addition to the above. He states, however, that, besides this tonnage, there is a considerable amount of ore partially blocked out, which indicates an additional 200,000 tons. The seventh annual meeting of the stockholders held yesterday was a successful one, thanks in a great measure to the lucid and comprehensive statement of the chairman—R. T. Bayliss—concerning the position in Mexico and the com-

pany's interests in the Mexico mines of El Oro and Somera Gold Mining Co. The local management may be congratulated in the appreciative sentiments of the stockholders, who unanimously voted a bonus of £1,500 to R. M. Raymond for his exceptional services, and also one of £750 to his assistant manager—A. F. Main.

Butte, Montana.

London Exploration Buys Interest in Butte Coalition.—Montana Output for 1906 to Show Increase.—Activity in Minnie Healey and West Colusa Mines.—Clark to Sink on Elm Orlu Mine.—Scarcity of Labor Curtails Output.—Butte and Superior Preparing for Extensive Development of Blackrock Group.—Company Organized for New Copper District.

The Rothschilds, through the London Exploration Co., have purchased 50,000 shares of the Butte Coalition Co.'s stock, at \$35. Philip L. Foster, of New York, the American representative of the London Exploration Co., spent several weeks in Butte examining the properties of the Butte Coalition Co., and on his report the Rothschilds made the purchase. Mr. Foster was in Butte at the time the division of the controverted orebodies was made between Coalition and Amalgamated and saw that Coalition was most generously treated, being granted practically all that Heinze, Coalition's predecessor, had contended for during

increase over this year should be fully 25%. It is expected that East Butte will next year be among the steady producers, and that Butte Coalition will increase its output more than 50%, while North Butte will add about 10% to its output. Anaconda and Parrot should also present a better showing than this year.

Work has been resumed on the Minnie Healey mine of the Butte Coalition Co., which had been closed for a month or more on account of the bad condition of the shaft. One hundred and fifty feet have been re-timbered, and the company hopes to be able to use the shaft now until the new one, which is being sunk on the Tramway, is finished. The Minnie Healey shaft, however, is unsafe in other places, and it is not certain that it will not necessitate another shut-down. When the Tramway shaft is completed connections will be made with the Minnie Healey mine and the latter property worked through the new opening. The new shaft is being sunk by the Butte Coalition and Butte & Boston jointly, as the two companies are joint owners of the Tramway.

It is expected that the West Colusa mine of the Boston & Montana Co., will be in operation again this week, as the re-timbering of the shaft has been completed. The

Montana.

his twelve years of litigation with Amalgamated. The stock purchase by the Rothschilds includes a large portion of the 30,000 shares of stock which the Guggenheim interests were some months ago trying to sell, which had been allotted to them at the time of the purchase of the Heinze interests by Coalition, the Guggenheims securing the stock at \$15 per share. Arthur C. Carson, who had been a member of the Coalition board of directors and general manager of its mining operations, resigned as director, and Mr. Foster was elected in his place to represent the London people. The same people in 1895 bought one-third of the stock of the Anaconda Co., taking over at that time the stock of the Hearst interests. They have since been in close touch with Butte companies and have made several attempts to increase their Butte holdings. It is understood that they offered to buy a block of North Butte, but not enough stock to satisfy them could be got together.

Amalgamated representatives express the opinion that the Montana output of copper for 1906 will be about 5% greater than it was last year, while other operators place the estimate as high as 10%. All agree, however, that next year, with a continuance of present conditions, the

Sketch Map of Telluride District, Colorado.

West Colusa shaft is 1,635 ft. deep, and as soon as regular work in the mine is resumed the shaft will also be sunk deeper, it being the intention of the company to put it to a depth of 2,000 ft. During September some ore, amounting to about 300 tons per day from this mine, was hoisted through the St. Lawrence shaft of the Anaconda Co. Ordinarily, when running full capacity, the West Colusa yields about 1,100 tons per day.

The shaft which is being put down by the Farrell and Alliance companies jointly, has reached a depth of 200 ft. and a station is being cut at that point. The first vein in the Alliance ground is only 25 ft. south of the shaft, and will be cross-cut in a short time. The same vein extends into the Farrell ground.

A hoisting engine capable of working to a depth of 1,500 ft., and two 100-h.p. boilers, are being placed on Clark's Elm Orlu mine, a property adjoining the mines of the Butte & Superior Copper Co. Senator Clark will sink a shaft 1,000 ft. deep on the Elm Orlu.

The East Butte Extension Co. is hoisting ore from four shafts on its properties and will soon be producing from the fifth, where development work is in progress. The company is also working the Arnold copper mine at

Rimini, Mont., and has made one shipment of ore assaying 30% copper.

The Boston & Montana Co., one of the Amalgamated sub-companies, is at present producing copper at the rate of 100,000,000 lb. per annum, but the improvements being made in the mines and enlargement of the smelter at Great Falls should add about 20,000,000 or 25,000,000 lb. to next year's output of copper. The main reason why the output this year in Montana will not come up to what was expected is the scarcity of labor that has prevailed during the past six months.

Preparations are under way to do extensive development work on the Blackrock group of mines which the Butte & Superior Copper Co. purchased from Senator Clark and associates. Lessees are working the upper levels of the mines and are shipping a lot of silver ore daily. The Butte & Superior Co. will, however, work it for copper, which is known to exist at greater depth. The shaft will be re-timbered from the surface to the 500-ft. level. It is expected that it will take 35 to 40 days to re-timber the shaft. By the time the work is completed the new hoist and machinery will be up and then the company will prosecute the work of sinking rapidly.

The Parrot Copper Co. is putting up equipment on the Little Mina, a property lying north of the Nipper, and will resume operations on it soon. The Little Mina has a shaft 800 ft. deep, and 200 ft. will be added to it.

The Amalgamated Co. has decided to develop and explore its coal beds on Bear creek. Several other companies have been operating there for many years and have opened good mines. The Amalgamated now has its experts there planning the work to be done.

The Ida-Montana Co. is putting in the foundation for a big hoisting plant on its property southeast of Butte, and in a short time sinking will be resumed.

The shaft being sunk jointly by the Farrell and Alliance companies, in the southeastern part of the city, cut into a good-sized vein of ore at a depth of 190 ft. It is the second vein cut by the shaft.

The Amazon-Butte Copper Co., which has started work on the surface to uncover one of the veins on the Amazon claim for the purpose of selecting a site for a shaft, has cut the apex of a copper-bearing vein. It is believed to be the same vein which has been opened in the Bullwhacker, Montgomery, Bertha, and other claims to the north of the Amazon.

F. Augustus Heinze, who has spent very little time in Montana since he sold his mining interests in the Butte Coalition Co., will continue to make Butte his headquarters. He has acquired control, for the United Copper, of a number of gold properties in Montana, lead mines in Idaho, and copper mines in Utah, the management of which will be under his personal direction.

The Park Copper Co., capitalized at 1,000,000 shares of \$1, has been organized. The company owns a number of claims in a new copper district on the Wise river, about 50 miles south and west of Butte. It is reported that a vein 60 ft. wide has been opened on the surface for a distance of 2,000 ft., and that ore from a shaft on the vein 15 ft. deep assays 12% copper.

The Butte & Bawn Co. is making good progress on several of its shafts, that on the Belinda having reached a depth of 450 ft., that of the Calumet 400 ft., and the Colleen Bawn 275 ft. The last named has for some time been in bad ground and has caused the company a lot of trouble. The company expects to run cross-cuts from the shafts at a depth of 500 feet.

In the Butte & London shaft, being sunk on the Greendale placer, a copper-bearing lode has been cut at a depth of about 650 ft., indicating the presence of veins in the ground. The shaft will be put down to a depth of 1,200 ft. before any cross-cutting will be done.

Toronto, Canada.

Stock Market is Active in Cobalt. — Chicago Syndicate Buys Interests in the Tretheway Mines. — The Watt Property Sold to a Canadian-American Syndicate. — New Vein Discovered on the Right of Way Company Mines. — Silver Queen is Producing Steadily.

American capitalists continue to make heavy investments in Cobalt mining properties, some important deals having been closed during the last few days, while many others are pending. The stock market is active, with shares in the mines of proved value advancing by leaps and bounds, especially in cases where a change of control and the introduction of new capital and improved methods give promise of rapid development and increased output.

The most noteworthy transaction is the sale of G. W. Tretheway's interests in the Tretheway mines to a Chicago syndicate, the personnel of which has not transpired. The properties affected are those of the Tretheway Silver-Cobalt Co., originally known as J. B. 7, and of the Coniagnus Mining Co. (J. B. 6) immediately adjoining, each being 40 acres in extent. The price paid is said to be about \$600,000. Toronto and other parties had been negotiating for the purchase of the controlling interest in the Tretheway Silver-Cobalt Co., and when the conclusion of the deal with the Chicago men was announced, injunctions were issued against Tretheway on behalf of W. G. Fox, a Toronto broker, and C. J. McCuaig, of Montreal, both of whom claimed that Tretheway had agreed to sell to them, and asked that he be restrained from parting with the shares. These proceedings, however, were too late, as the formal transfer had been effected. As big figures are specified in the papers there is a shrewd suspicion on the part of some that the injunction proceedings may have been undertaken to boom the stock.

The Watt property, adjoining the McLeod-Glending, Rothschild, Nova Scotia, and other noted mines, has been bought by a Canadian-American syndicate, represented by Frank L. Culver. A carload of ore, shipped by the late owners, proved of good quality, and another is awaiting shipment. Modern machinery will at once be introduced by the new management.

The Right of Way Co. has fifteen men at work and five veins have been traced. Veins No. 1 and 2 are directly opposite La Rose mine, and were for some time in dispute between the mine-owners and the Provincial Government, the courts deciding in favor of the latter. Twenty feet below these a new vein has been discovered, and followed for 75 ft. It is a calcite vein, carrying much free silver. Vein No. 1 is on the portion of Cobalt townsite included in the company's holdings, and No. 5 is a continuation of a rich vein on the Silver Queen.

At the Silver Queen driving has been carried on at the 65-ft. level for about 100 ft., and much rich ore taken out. The vein here is about 18 in. wide. A large space has been blasted out and a receiver installed so as to keep the drills steadily at work. The ore is trucked to the shaft and raised by a steam-hoist. Two 60-h.p. boilers, an Allis-Chalmers air-compressor, hoisting plant, and dynamos have been installed. The main shaft is down nearly 100 ft. and driving will be carried on when this level is reached.

Mr. Scott, the superintendent of the Foster mine, is in Toronto procuring modern machinery and engaging laborers.

F. E. Hewitt, representing extensive Pittsburg interests, is seeking for opportunities to make large investments in Cobalt propositions.

W. G. Miller has returned to take charge of Government operations on the Gillies timber limit.

Salt Lake, Utah.

Concentrator for Utah Development Co.—New Company to Operate at Ely.—Reduction of Freight Charges for Tintic Ore.—Fortuna Mining Co. to Have Aerial Tramway.—Strike on Scottish Chief.

The Markham Gulch Milling Co. has been organized by E. R. Hastings, J. W. Horne, and A. J. Orem, of Boston. Ground has been broken for a concentrating mill to have capacity for the treatment of 200 tons of ore daily from the Utah Apex and Utah Development companies' mines, both of which are practically under the same control and management. The first-named company has been sending ore to a custom mill for treatment and last week marketed concentrate which netted \$40 per ton.

Copper Glance, a Bingham property, is developing quite satisfactorily and is believed to have an extension of the orebody opened in the Ohio copper mine. There has been much local demand for the stock, which has been bought at a big advance.

Eastern parties are considering the purchase of a control of the Standard copper property, in Bingham, and an examination is in progress.

The Salt Lake Ely Mining Co. has been organized to operate at Ely, Nev. Eleven claims have been acquired, all located at Ely and not far from the properties of the Cumberland Ely and Nevada Con. companies.

The Tintic Mine Owners' Association has succeeded in obtaining from the railroad companies entering that camp a slight reduction of freight charges on ore shipped to the Salt Lake valley for smelting. The reduction amounts to 25c. per ton on all ore of a gross valuation of \$25 per ton. The reduction, however, is not satisfactory to the producers who contend that they are not being accorded the treatment given to producers of other districts of the State where charges are based on the net value of the ore shipped.

The Utah Development Co., of Bingham, has been shipping concentrate to the Salt Lake smelters which netted about \$10 per ton.

The Fortuna Mining Co., of Bingham, has completed a survey for an aerial tramway system, which will convey ore from the mine to the Copper Belt railroad. Sidney Bamberger, of Salt Lake, is manager of this company.

The ore shipments from Park City last week amounted to 1,904 tons, the contributing mines and amounts being: Daly-Judge, 603; Silver King, 613; Little Bell, 21; Ontario, 53; New York, 10; Daly-West, 502; other mines, 102 tons.

The management of the Scottish Chief mine, near Park City, has reported an important strike of ore on the 300-ft. level, where a 3-ft. vein of ore carrying 7.5% copper, 32 oz. silver, 6% lead, and \$1.80 in gold, has been opened.

Development work will shortly be resumed on the Silver Bell property at Park City. N. W. Sonnedeker, of Salt Lake, is manager.

The Golden Bell Mining Co., to operate in Park City, has been formed. L. B. Wight, of Park City, is secretary.

Word comes from Gold Butte, Lincoln county, Nevada, that the adit being driven to develop the Gold Butte mine has cut another orebody. This property is owned by a Salt Lake syndicate.

The directors of the Utah mine, at Fish Springs, have posted the regular dividend of \$3,000, and an extra dividend of \$2,000.

The directors of the Uncle Sam Con. Mining Co., operating in the Tintic mining district, have decided to pass the October dividend. A shortage of cars is given as a

reason for not getting a larger tonnage to market during the past month.

The management of the Scranton Mining Co. has shipped 250 tons of ore to New York to be tested. The company may decide to build a plant for the treatment of low-grade ore on the ground. W. H. Brammel, of Salt Lake, is manager.

The Bingham Con. is making some important changes at its smelter at Bingham Junction. To make room for one of the new reverberatories, a blast-furnace (in use for some time) has been torn out. The foundation has been completed for the new stack, to be built of reinforced concrete and to a height of 250 ft. This company has expended, it is claimed, \$175,000 for experiments and in the installation of a system for the saving of the flue dust and diluting of the sulphurous gases.

Owing to a coal shortage, the Consolidated Mercur Gold Mines Co. at Mercur has kept its mill in operation under the most difficult circumstances.

Cripple Creek, Colorado.

Vein Cut in Morning Glory No. 4. — New Mill to Be Built at Bull Hill. Satisfactory Developments at Portland Mine.

Among the various leases operated by the Western Investment Co. is one on the Morning Glory No. 4 claim. A cross-cut is being driven at a depth of 550 ft. and a vein has recently been encountered, which, when developed more thoroughly, is expected to open up into an orebody of fair size.—The erection of another cyanide mill will be commenced shortly in the district. J. B. Shipman and R. J. Grant, formerly connected with Stratton's Independence, Ltd., propose to construct a mill on the ground of the Lillie mine, belonging to the Vindicator Gold Mining Co., at Bull Hill. The capacity will be 100 tons per day and the dumps of the Lillie and Vindicator as well as the low-grade ores of those mines are to be treated.

The Portland Gold Mining Co. paid a quarterly dividend of five cents per share on October 15, amounting to \$150,000, bringing the amount of the total dividends paid by this company to date up to \$7,147,000. A circular letter by Irving Howbert, the president, has been sent to the shareholders, in which it is stated that the three winzes which have been sunk from the 1,100-ft. level have shown up very well. Two of these are near No. 1 shaft and a third a short distance from No. 2. One of those near No. 1 shaft has been sunk 150 ft. in good ore, while the other is now down 50 ft. with an excellent showing at the bottom.

High-grade ore has been encountered in the winze near No. 2 shaft all the way to a depth of 140 ft. This development work shows that the orebodies continue to a greater depth than heretofore supposed.—The output from the Portland mine since the beginning of the year has averaged 9,000 tons per month, which compares favorably with the production for the last two years. The value per ton has decreased somewhat. The reasons stated for this decrease are: (1) Veins have been mined to their full width so that they will not have to be gone over again, taking out low-grade ore from the walls. (2) The timber in the old stopes near shaft No. 1 is decaying rapidly, necessitating either abandoning the fair-grade ore still remaining on the walls of those stopes, re-timbering at a heavy cost, or to extract this ore as quickly as possible. The latter course has been adopted, giving a fair profit in spite of the rather high cost of mining. The high-grade ore was taken out of these stopes six years ago. The circular also states that the company has no intention of leasing any portion of the mine.

Mining Summary.

ARIZONA.

COCHISE COUNTY.

A strike has been made in the mine owned by T. I. Coleman and L. W. Riggins, situated near Troy. A four-foot vein of high-grade ore has been proved by an inclined shaft 120 ft. deep and an adit 180 ft. long. The vein lies in a contact between quartzite and schist, the vein-filling being principally rose quartz.—Copper ore assaying 40% has been encountered in a two-foot vein in the Riverside group. The ore is mainly chalcopryite and bornite.

GILA COUNTY.

The sulphide vein has been cut on the 800 level of the Copper Hill mine belonging to the Arizona Commercial Copper Co. The size and value of the sulphide orebody has not yet been determined, and it will probably be slow work opening it up, as the ground is wet and very heavy.—The Globe Consolidated is going ahead with the work of sinking and equipping the Gem shaft, which has reached a depth of about 65 ft. The whim on the shaft was replaced by a steam-hoist last Saturday.

MOHAVE COUNTY.

(Special Correspondence).—Unprecedented activity in the mines of this county is reported.—It is now understood that a sale of the Bimetal mine, at Kingman, will soon be made for a large figure. The mine is one of the largest gold-bearing properties in the county. Its proximity to the Santa Fe Pacific railroad makes it very desirable.—The Arizona-Mexican Mining & Smelting Co. is working the Champion mine in Todd basin and getting rich lead ore. The mine was a big producer in the early days of the camp.—Wells Bros. have located the old I. & L. mine in the Wallapai mountains 15 miles southeast of Kingman and have been at work on it since the cool weather began. A drift was run in to cut the vein at a depth of about 500 ft., and from this drift ore running high in silver is being taken. The average of a big pay-streak is said to be \$75, but ore running several hundred dollars can be sorted.—S. A. Taylor has four men at work on his mine at Mineral Park. The orebody is one of the largest and richest in the county, 14 ft. of it running better than \$6 gold and \$3 silver per ton. The last carload shipment from the property netted more than \$2,000. The depth attained in the mine is over 100 ft. and sinking will soon be resumed.—U. H. Taggart, of the H. H. Taggart Mercantile Co., of Kingman, has just returned from Los Angeles, where he made a deal on the C. O. D. mine at Cerbat, and the purchasers will soon visit the property. The C. O. D. mine is one of the best properties in Wallapai district.—It is understood that there will be a consolidation of several of the big mines of Cerbat, and that later a large reduction plant will be installed to handle the ore. The mines composing the consolidation are all good bearing properties, and lie close together, making it possible to work them through one shaft.—Stockton Hill is active in mining operations. The De la Fontaine mine is being worked, while at the mill, work is progressing rapidly. At the Star Spangled Banner mine, the Arizona-Mexican Mining & Smelter Co. is taking out rich lead ore. The mill is completed and will soon be put in commission.—Barney Perkins, of Mineral Park, is preparing for an extended prospecting trip into the country south of Bill Williams fork. That section of the country is reputed to be rich in gold and copper, and will be thoroughly prospected this fall.

Phoenix, October 12.

YAVAPAI COUNTY.

An important mining deal was perfected yesterday when the title to a one-third interest in the Snowflake and Cedar mining claims in the Cherry Creek district was passed from F. L. Scheerer to W. C. Metzger. These claims are among the most promising in the district and will, within a short time, be the scene of active operations.—A shaft on the Snowflake claim, sunk to a depth of 150 ft., from which levels have been run, exposes a body of free-milling gold ore of good grade, averaging a width of 40 in., while surface openings on the other claims show the vein to be equally prom-

ising. In the immediate vicinity of this property the Climax Mining Co. is engaged in the installation of a mill which it is expected will be in running order within the next thirty days, when a force of men will be put to work extracting ore from large bodies which have already been opened.

CALIFORNIA.

INYO COUNTY.

The Lucky Jim mine, three miles north of Darwin, has been sold by J. A. McKenzie to the New Coso Mining Co. The Lucky Jim, with the Christmas Gift, is one of the old-time properties of that part of the county. A great deal of work has been done there. During Darwin's best days the Lucky Jim camp had a population of 300. The largest two-stack smelter in the county was built at Darwin for reducing ores from the two mines. The hoisting plant over one shaft was burned several years ago, but was replaced with another by Mr. McKenzie. The deepest mining is 425 ft. below the surface.

NEVADA COUNTY.

Asbestos has been found in the Washington district, and samples were shown here yesterday by J. T. Dillon and F. T. Smith. The deposit is situated on the South Yuba river on the north side, and is about 200 ft. wide. In this formation there are hundreds of stringers of asbestos, and the find should prove a valuable one.—The new five-stamp mill at the Republic mine, near Graniteville, is completed, and the framework has been put up for five additional stamps. It is the intention of the owners of the mine, McLean, Foss & Co., to keep the stamp-mill running steadily all winter.—After more than a year's trouble the Ironclad mine has finally been unwatered, with the result that the management has been able to enter the 400-ft. level and examine the vein. In the stope the vein is two feet wide and has the appearance of containing valuable milling ore. The water is running in at about 200 gal. per min., and the pumps have a capacity of four hundred gallons.

George Shebley and Joseph Orzalli have bought a five-stamp mill and will move it from You Bet to their mine near Chicago Park. A tunnel is being run to strike the bottom of the shaft, which is down 90 ft.—The Union Hill Con. mine on Banner hill, near Nevada City, has been sold to John J. Myers and C. F. Humphrey, who are interested in the Murchie mine at Nevada City. The Union mine was owned by a local company, which has been operating the mine for some time and has sunk the shaft 200 ft. and driven about 400 ft. The local owners were not provided with means to do development work and erect the machinery necessary for deep mining. The property consists of two claims and runs 3,000 ft. on the vein. The new owners will form a company to be known as the Union Con. Mining Co., and will sink the shaft several hundred feet.

SAN BERNARDINO COUNTY.

The American Eagle Mining Co. expects to commence active development work about October 15. H. H. Ahrens is to take personal charge of the work. The mines are situated in the Whipple mountains, 40 miles south of Needles, and have been largely developed. The orebodies run high in copper and therefore shipping facilities to the smelter at Needles are greatly needed.

SHASTA COUNTY.

T. W. Lawson issued a statement to the stockholders of the Trinity Copper Co. to the effect that all the general conditions and details for the contract between his company and the smelter people had been agreed upon, and that it would be executed by order of the directors of both companies at meetings to be held within two weeks.—N. W. Keith, superintendent of the Mad Ox mine, near Whiskey town, was in Redding last week to dispose of a gold brick—the product of the first run made with the new 10-stamp mill. From 16 to 20 men are employed steadily at the mine. The Cariboo Gold Mining Co., which has a bond on the Mad Ox, is working the mine on a systematic plan of development. The owners are J. F. Schilling, Louis Reel, and Woodward.

Experimental works are being erected on the Pit river,

east of the mouth of the McCloud, to test the possibility of working the iron ore deposits by means of the Heroult process. The company experimenting on the iron deposits is under the direction of H. H. Noble, president of the Northern California Power Co., and C. E. Petinot. C. B. Morgan is in charge of the operations on the Pit river.

The Balakala Con. Copper Co. has received patents on the Gold Nugget, Togo, and Nogi claims. These cover an area on the Coram townsite, the title of which was contested in the spring. The laying of track on the smelter spur has now been begun and the heavy grading finished. This will overcome the transport difficulties which have been a serious hindrance in the building of the new smelter town. — Increased activity is reported at the Midas mine, in Harrison gulch, since the completion of the 700-ft. raise, which is now being equipped as the main hoisting shaft.

TUOLUMNE COUNTY.

(Special Correspondence).—It is reported that the Standard Electric Co. intends extending its wires to Groveland within the next few weeks and that it will compete with the local electric company in supplying power to the mines in that vicinity. The local company is already supplying several mines in that neighborhood, among which are the Mack and Longfellow. — Operations are soon to be resumed at the Arbona mine near Tuttletown, which recently passed from the control of the Equitable Mining Co. to the Calmas Co., of Boston, Mass., a newly organized corporation. — A steam-hoist has been installed at the Eureka mine, situated one mile east of Jacksonville. Sinking is to be resumed. The shaft is 200 ft. deep. — The Tuolumne County Water & Electric Power Co. will shortly run wires from Rawhide to the marble quarries near Columbia by way of Tuttletown for the purpose of conveying power to the points named. — Liens aggregating \$4,000 have been filed against the Black Oak mine by former employees. — A hoist and pump will shortly be installed at the Bullion mine on Knight's Creek and development work vigorously prosecuted. Rich ore has been uncovered at the 80-ft. level, where the vein is eight feet wide. — Several men have been put to work at the Hope mine near Sonora, a combination pocket and milling property. An adit is being driven to open up ore-bodies at a considerable depth. Heretofore it has been worked by means of a shaft.

Tuolumne, October 15.

W. J. McRay, manager of the Clio property at Jacksonville, returned from Los Angeles to resume sinking operations at this property. The shaft is to be carried down to 600 ft., the present depth being 400 feet.

YUBA COUNTY.

Walter E. Trent is engaged in prospecting for a copper lode on the Mackey ranch, at Camptonville. The shaft is now down about 50 ft., and Mr. Trent will let a contract to sink it 50 ft. deeper.

The South Yuba Mining Co. has sold its holdings comprising 10 claims on the north bank of the South Yuba river. The mine was recently examined by J. Neill and T. Varden. Six adits have been driven on the property, almost from the top of the mountain down to the bed of the river, and each has struck the orebody, which has been cut in places from 38 to 56 ft. without going through the lode. The copper ore ranges from 2½ to 30%, besides carrying \$5 per ton in gold and silver.

COLORADO.

BOULDER COUNTY.

(Special Correspondence).—The Fourth of July mines being operated by the Consolidated Copper M., M. & S. Co., on the south base of Arapahoe peak, has an adit 2,760 ft. which cuts the hill 700 ft. below the surface. The deepest shaft on the property is 360 ft., but, on account of the large volume of water in the shaft, they were obliged to abandon same and start a 3,000-ft. adit to tap the orebody underneath the shaft. This adit was started some four years ago. From present indications they will have to drive the adit something like 75 ft. before tapping the vein which they are after, and after that will make a raise to the surface. Several promising veins have been encountered

since the adit was started. J. B. Johnson is president and M. P. Givens secretary.

Eldora, October 13.

CLEAR CREEK COUNTY.

(Special Correspondence).—T. H. Tracy, manager of the Taawasa Gold Mining & Cyaniding Co., expects to have his mill running within the next thirty days. He has overhauled the old mill belonging to the Idaho Springs Reduction Co. and put it in first-class shape for handling the ore from the Taawasa mine, as well as their property at Empire. Some original ideas are being carried out in this plant, especially the dewatering system for handling the concentrate. Instead of having a concentrate box at each table the concentrate will drop from the table to a slot in the floor to a conveying belt which conveys it to the drying apparatus. This scheme, if a success, will be quite a departure from the ordinary way of handling concentrate.

Idaho Springs, October 13.

A large vein was encountered in the breast of the New-house adit and a large quantity of mineralized vein matter broken through, making the width of the vein as near as can be ascertained about 27 ft. None of the samples of the ore assayed enough to warrant stoping, the point of intersection being a barren place in the vein with no slips or feeders coming in. — The old Wing mine, located on Democrat mountain, which has remained in idleness since 1877, has been leased to Chas. Estelle & Co. for a term of years. Development has already been put under way. In the breast of the adit there is now showing from 5 to 16 in. of ore which carries average values of 19 oz. silver and 30% lead. — William Rogers, manager of the Santiago mill, has purchased a small dump at the Burleigh tunnel workings from the Dives-Pelican Seven-Thirty Mining Co. The entire product is to be hauled to the mill at Georgetown, where it will receive concentration.

LAKE COUNTY.

S. Storm, the owner of the Bedford group of claims in Sayer's gulch, arrived last week and has let a contract to E. B. Harlan to continue driving on the Delaware claim. — The recent development work in the lower adit on the Golden Fleece group, operated by the Parrot Mining & Milling Co., has opened up a body of very good ore, assaying from 5½ to 22% copper, and carrying also good values in gold and silver. High-grade copper ore is unusual on Bull hill, and the Golden Fleece is the only place where this metal has been found in paying quantities. The adit has been driven over 300 ft., and is at present 200 ft. below the surface; the last 40 ft. is in rock thoroughly mineralized, and in which frequent streaks of good ore have been found.

PITKIN COUNTY.

A big strike is reported to have been made at the second level of the Smuggler-Union mine. The ore was discovered first in small pockets, but in the last day or two has developed into a big, rich strike.

PUEBLO COUNTY.

Four men were killed as the result of the blowing out of the bosh in furnace D at the Minnequa plant of the Colorado Fuel & Iron Co. Several others are said to be more or less burned by the hot iron. Although constantly in use for years it was believed to be in a perfectly safe condition, and aside from the fact that the furnace had probably been weakened by the heat from within, no explanation is offered as to the cause. This is the second accident of the kind at the plant in the last two years, although no serious trouble has been experienced with the furnaces since J. H. Means, the present superintendent, took charge.

SAN JUAN COUNTY.

The Animas Power Co.'s plant near Rockwood, which has been supplying power to various mines and mills in the district, had a serious accident a few days ago. It seems that while one of the engineers was shutting off the water in the plant, he closed the valve too quickly, with the result that the pipe could not withstand the terrific pressure and was forced apart in several places. It will probably be several days before the company is ready to furnish power to its customers, but luckily many of the properties are equip-

ped with steam-plants, so that they can continue operations. Several hundred feet of steel pipe was rendered useless as a result of the accident.

SUMMIT COUNTY.

(Special Correspondence).—An important strike has been made on the Lucky mine on Mineral Point, the property of the Beaver Creek Mining & Milling Co. The ore is high grade in lead and carries gold and silver, so that it can be shipped as it is mined. The property is also producing large quantities of mill-dirt which is being treated by its own concentration plant.—The Jessie is now running smoothly and is employing 28 men continuously. The 40-stamp mill is running full time and is producing from \$3,000 to \$4,000 of gold per month.—C. L. Lightburn, of Denver, is making arrangements for resumption of work on the property of the Gold Run Mining & Milling Co.—The Country Boy, on Nigger Hill, is preparing a shipment of 500 tons of high-grade zinc ore for Iola, Kansas.—The Pennsylvania is making regular shipments to the Chamberlain & Dillingham Ore Co.'s works at Breckenridge. Mr. Lewald, general manager, states that he will install a large electric power-plant on the Snake river next spring and double the capacity of his mill.—E. E. Loring, manager of the Hoosier Creek Gold Mining Co., is making arrangements for unwatering the shaft, and to continue sinking. If the vein continues to dip at its present angle, the shaft should pass through it at 300 ft. The shaft is now down 100 ft. and is equipped with a good hoist. The vein is 105 ft. away from the shaft at the present level and has been reached by cross-cut. Raises and stopes on the vein have opened up good ore.—The Wonderful-London, which adjoins the Hoosier Creek, has its main shaft down over 400 ft. As soon as the lime contact is reached, drifts and raises will be started to block out ore. The ore already shipped is high grade.

The Atlantic mine on North Star is making regular shipments of gold ore which run from 3 to 5 oz.—The Pacific is also shipping to the smelters, a good grade of galena carrying gold. The property is being worked by W. P. Condon under lease. The main tunnel of the Gold-Dust property which adjoins it is being used as a right-of-way. A winze 75 ft. deep has been sunk below the tunnel, and drifts and raises have been run in the ore from the bottom of the winze.—The Gold-Dust company is now sinking on the ore-shoot recently opened up, and will operate below the main tunnel level by winzes and drifts. The pumping plant recently installed is working well. The Excelsior mine, at Frisco, will soon be working a full force, taking out shipping ore. The ore averages over \$40 per ton. Besides the high-grade streaks, the veins carry large quantities of milling ore, which can be treated by the company's own plant. Excavation is being made for the compressor plant.—At the Square Deal, in the North Ten Mile Canyon, the camp buildings are completed. The main adit is now in over 200 ft. toward the centre of Chief mountain, where rich veins are expected to be cut. The veins on the surface make a fine showing. W. W. Wonser, treasurer of the company, has been at the mine with Eastern visitors.—Jack Norman has struck rich ore in the Hope, which adjoins the Square Deal. He is building a cabin and blacksmith shop and will immediately start a tunnel.—Atherton and party have let a contract for the location of work on their claims on Chief mountain.—The King Solomon is continuing its main development adit toward Mount Royal.—The Columbine, at Robinson, has resumed its old-time activity under the management of Samuel Doran.—The Summit Mining Co. is operating the east shaft of the Robinson mine, which is down 300 ft., and is to be extended 225 ft., to the second contact. The property is well equipped with hoisting machinery and a battery of three large boilers and pumps. Frank Bulkley is manager.

Breckenridge, October 10.

TELLER COUNTY.

William Foley, manager for the Aetna Mining & Development Co., operating a lease on the Index mine on Gold hill, has cross-cut in the fourth level the Pointer vein, for which he has been searching for several weeks. The vein carries good values.

IDAHO.

SHOSHONE COUNTY.

The California mine on Nine Mile, two miles from Wallace, has struck a rich shoot in the No. 4 level. The new orebody has already been proved to be over 15 ft. wide. About 15 or 18 in. of it is solid galena. The rest of the 15 ft. is all high-grade concentrating ore and will probably average as much as 20% in lead. Owing to the dip of the vein, the 300 ft. of vertical depth now obtained will give approximately 800 ft. of backs.—North & Eberhardt have recently bonded for Charles F. O. Merian 800,000 shares of the capital stock of the Black Bear Fraction Mining Co. The property consists of four claims and a fraction and is traversed by two veins. One is known as the Brown Cub vein and the other is the same which contained the great Black Bear ore-shoot of the Frisco mine.

NEVADA.

LINCOLN COUNTY.

(Special Correspondence).—According to the latest information from the headquarters of the Santa Fe railroad in Los Angeles, within seven weeks the first trainload of passengers will be pulled into Searchlight. This means much to the camp as machinery and supplies now have to be hauled 22 miles by team, and the four stages handling the passenger traffic are barely equal to the task.

In the shaft of the Searchlight Consolidated M. & M. Co., good showings have been encountered and high assays obtained from the surface croppings on the Oregon group.

The Searchlight, Wyoming, at a depth of 209 ft. has struck good ore but will continue sinking and driving.—The Bumberger-Wheatley Mining Co. has done 500 ft. of sinking and driving, and trenching has been started. It is the intention of the company to develop all the claims as fast as the work can be accomplished. The ore has averaged \$7 per ton from the grass roots down and is now running as high as \$40.—All the contract work has been completed on the Nevada Consolidated property, the shaft on the Loder claim being 225 ft. down with good showings.—In the Drake shaft on the Quartette property they have sunk 250 ft., but encountered so much water they did not carry out their original plan of cross-cutting at that level. Instead they are cross-cutting toward the main vein of the Quartette itself. This property still continues to get better and from present appearances there seems to be an enormous supply of ore in sight. It is stated on good authority that the dividends will soon be increased from \$15,000 per month to \$30,000, and this, considering the extensive improvements in the company's buildings, is a remarkable showing.

The Cyrus Noble Extension shaft is down 164 ft. and at 158 ft. they encountered an east and west vein which is undoubtedly the vein of the Duplex as the ore in general appearance is exactly the same and carries high values. The Duplex which adjoins this property is the first mine located in Searchlight and was sold to John Brockman of the Commonwealth mines of Arizona and Count Portalis for \$265,000. The Cyrus Noble Extension shaft is only 1,500 ft. from the Duplex shaft.

Searchlight, October 12.

Big strikes are being made 20 miles southwest from Eldorado canyon, 20 miles northwest of Searchlight, and five miles from Crescent, Nevada, in what is known as the Golden Triangle. The new camp is situated in the Bird Spring range in Lincoln county, southern Nevada, two miles from the main line of the Clark road.

WHITE PINE COUNTY.

The new railroad running between Cobre and Ely, a distance of 140 miles, has been completed and is now in operation. Nevada Consolidated interests, which control the road, are now in a position to push the work of building their smelter and concentrator to completion. It was necessary to complete the road before the machinery could be shipped to the Nevada Con. Co.'s property.

OREGON.

JOSEPHINE COUNTY.

An important mineral find has been made almost within the limits of the city of Grants Pass, the discovery consist-

ing of an eight-foot vein of molybdenite. Development will be immediately commenced.

UTAH.

SALT LAKE COUNTY.

The Western Utah Copper Co., controlled by D. MacVichie and others associated with Bingham interests, has been recently formed to operate the Gold Hill mine in the Deep Creek district. The mine was secured under option several years ago, and since that time active development has been carried out with gratifying results. The property is 30 miles from the main line of the Western Pacific railroad and is situated near Clifton in the Deep Creek district. The installation of the new compressor at the Fortuna mine at Bingham is progressing.—A decided victory for the smelting industry of the Salt Lake valley was the decision rendered on Friday afternoon in the case of Morthouse against the Utah Consolidated Co. The plaintiff several months ago brought suit against the Utah Consolidated for damages said to be caused to the plaintiff's crops by the smoke from the smelter of the defendant. Damages were asked to the extent of \$3,000, and the case was decided in favor of the Utah Consolidated Company.

WASHINGTON.

STEVENS COUNTY.

The smelter at Northport has been unable to start operations owing to the shortage of coke caused by the strike at Fernie, B. C. One furnace was ready to start up on October 15, a second on November 1, and a third as soon as the present contract for Le Roi ore at the Trail smelter was out. There are six furnaces at Northport which can treat 1,200 tons of Le Roi ore per day.

FERRY COUNTY.

After testing the ore from the Republic camp Mr. Potter considers that he can successfully treat it at the place of production by a milling process, to come within a reasonable cost and enable ore of as low a grade as \$6 per ton to be mined and treated at a small profit. It is proposed to amalgamate the mines, equip them with modern and more powerful machinery, and work on an extensive scale.—The Keller & Indiana Con. Smelting Co. has completed the construction of its smelting plant.

OKANOGAN COUNTY.

(Special Correspondence).—The Palmer Mountain Tunnel & Power Co. is employing electric drills, grading for the mill, near the mouth of the Palmer Mountain tunnel. It is expected the machinery for the mill will be delivered by the Vancouver, Victoria & Eastern railway at Nighthawk as soon as the rails are laid to that point, about the last of December. From Nighthawk it will be hauled to the mill-site by teams, a distance of 10 miles. An electric engine will be used for the removal of ore and waste from the adit. The light T rails are being replaced by heavier ones. The extension of the adit into the hill and the exploration of the veins already encountered will be started without delay.—In the Copper World Extension mine a cross-cut has been driven 60 ft. on the 300-ft. level, and the shaft is being sunk from the 300 to the 400-ft. level. A change has taken place in the management of this property. Henry Bahrs, who has had charge since the incorporation of the company, has been superseded by R. J. Thomas, of Findlay, Ohio, and Bert Wentworth's place, as foreman, has been given to Clayton Baldwin.—The Ruby mine, at the base of Mt. Chapaca, is looking well, and the rich streak of sulphantimoniate ore still holds out in the raise. Mr. Harman, manager, expects to take out 1,000 tons of an average value of \$100 per ton by the time the Vancouver, Victoria & Eastern railway gets to the mine. The drift from the No. 1 adit on the Phil Sheridan mine, at Sheridan camp, is in 227 ft., and the face, 4 ft. wide, is in good ore. Recently 19 tons of ore was shipped to the Granby smelter which assayed \$59 per ton. A large tonnage of low-grade ore remains on the dump, which assays from \$12 to \$25 per ton. No. 2 adit has been driven 30 ft. on the vein. No. 4 adit will be started shortly and given an additional 75 ft. vertical depth below the No. 3. The latter is in 116 ft. and will tap the

vein at a depth of 152 ft. It has about 150 ft. further to run. The company anticipates letting a contract for the work and is figuring on a 50-ton concentrating mill, to be installed a half-mile distant, on the west fork of Toroda creek. The company also intends building a tramway from the mine to the mill.—The Viola Copper-Gold Mining Co. has driven an open-cut 125 ft. across a vein on the Jupiter claim, which is 15 ft. deep at the face and in galena with lead carbonate. The open-cut is five feet wide and shows low-grade ore on both sides. In the floor is quartzite which assays in gold, silver, copper, and lead. On the Americanetta claim two cross-cut tunnels have been driven.—The Viola group is on the southern slope of Eneas mountain, 18 miles south of Loomis.

Loomis, October 10.

O. D. F. O. Mudnutt, general manager of the Multnomah Mining, Milling & Development Co., announces that work is being pushed on three groups in Nespelem camp. The Nespelem river will be dammed preparatory to installing a power plant.

SPOKANE COUNTY.

Frank T. Post, of Spokane, has bought the Spokane Smelting & Refining Co.'s smelter, five miles west of Spokane, and it is given out it will be put into operation some time in October. The plant was erected 16 years ago, but it has never produced bullion. Philadelphia and Grand Rapids, Mich., capital is said to be behind the deal.

STEVENS COUNTY.

The Young tungsten mines, south of Deer Trail, are reported to have been sold to German interests identified with the Krupps. The claims were located 12 years ago by C. H. Young and M. F. Gibson, of Davenport. The purchasers announce that they will erect a concentrator this fall and ship the product to the Krupp ordnance works. The same people have taken a bond on molybdenum mines, which are 15 miles north of Davenport, in Lincoln county. These are known as the Putney Butte mines.

WYOMING.

CONVERSE COUNTY.

A large acreage of Niobrara shale, within six miles of Douglas, has been taken up to supply a proposed Portland cement plant. The shale at Douglas lies flat on the surface for a depth of 25 ft., so that it can be dug with a minimum of expense, it being necessary to remove practically none of the surface. The Douglas gas wells are within seven miles.—State Geologist H. C. Beeler is investigating the shale possibilities of the newly opened Wind River reservation. If good shales are found there, the attention of manufacturers will be called to the fact, and the new reclamation enterprises in the reservation may have the advantage of cement made close at hand.

BRITISH COLUMBIA.

The strike of the employees of the Crow's Nest Pass Coal Co. is not so disastrous to the mines and smelters as was at first expected. Advantage is being taken of the shortage of coke to attend to repairing, developing, and shaft sinking, with the result that a full force of men is working at most camps.

At the Centre Star, the 650-h.p. Westinghouse motor is in position in the compressor building, and the cement foundation for the new hoist is completed. At Le Roi, the sinking of the shaft from 1,150 ft. will begin immediately. The development of the new territory west of the dike in the Black Bear is being proceeded with, and the ore-shoots there are looking fairly well.

Charles Biesel, the superintendent of the Snowshoe, has discharged the employees and temporarily closed down the mine, owing to the shortage of coke.

The smelter of the Consolidated Co., at Trail, will be closed down in a day or two for want of coke. The management will take advantage of the opportunity afforded to make extensive repairs and improvements to the plant, which have been under contemplation, but which could not be successfully accomplished while everything was in operation. This work will give employment to nearly all the employees.

Personal.

C. A. MOLSON is at Butte.

J. R. FINLAY is at Goldfield.

ARTHUR L. PEARSE is at Salt Lake City.

J. PARKE CHANNING has returned to New York.

F. W. BRADLEY and MARK L. REQUA are in New York.

J. W. MERCER was married at London on September 14.

R. A. PARKER is examining mines in southwestern Colorado.

W. B. DEVEREUX, JR., has returned to New York from Kendall, Montana.

H. VINCENT WALLACE has returned from England to Nogales, Arizona.

SAM. W. CHEYNEY is manager of the Sierra Alta mine in Sierra county, California.

R. B. WATSON, of New York, is inspecting mines in the Cananea district, Mexico.

HENRY HARRIS is superintendent of the Hall smelter at Nelson, British Columbia.

GEORGE E. GUNN is manager of the Cumberland-Ely copper mines, at Ely, Nevada.

J. P. HARVEY is superintendent of the Furnace Creek mine in Inyo county, California.

GILBERT T. ROOTE has returned to San Francisco from examining mines in Trinity county.

C. J. REYNOLDS is superintendent for the Guerrero Development Co., at Chilpancingo, Mexico.

M. L. McDONALD is inspecting mining properties near Forest City, Sierra county, California.

F. W. MACLENNAN has returned to Salt Lake from an investigation of mines at Pioche, Nevada.

ROBERT W. DAVIS, JR., manager of the Old Hundred Mining Co., Silverton, Colo., is in Denver.

A. W. HUDSON has been appointed manager for the Rigby reduction works at Mayer, Arizona.

ALEXANDER N. ALLISON is the new superintendent of the Annie Laurie mine at Kimberly, Utah.

W. C. THOMAS is in charge of the Boundary Falls smelter of the Dominion Copper Co., British Columbia.

CHARLES HUTCHINSON has returned to San Francisco from the American Mining Congress at Denver.

MARK R. LAMB, recently appointed consulting engineer to Chas. Butters & Co., is on the way to South Dakota.

NEWTON W. EMMENS has been appointed manager for the Broadview mine, Trout Lake City, British Columbia.

FRANK H. PROBERT has returned from an extended trip through the Guadalupe y Calvo district of Chihuahua, Mexico.

GEORGE A. PACKARD passed through San Francisco on October 16, and will visit Goldfield and Denver on his way back to Boston.

H. L. JOHNSON has been appointed superintendent of the Tightner mine, near Downieville, Cal., in place of W. S. Hoskins, resigned.

CYRUS W. DAVIS, treasurer of the Gold King and Gold Prince mines, is in Denver on his way to visit the mines at Silverton from Waterville, Maine.

JOHN L. WITNEY has resigned as superintendent for the Lowell & California Mining Co., and has opened an office at 417 Hellman Bdg., Los Angeles.

E. W. SEBBEN has returned to Denver from Silver City, N. M., where he made an examination of an old Spanish mine. He is now at Wickenburg, Arizona.

THEO. B. COMSTOCK is engaged in extensive investigations in southern California, Mexico, and Nevada in the interest of five distinct groups of Los Angeles clients.

Trade Treatises.

ALLIS-CHALMERS Co. have issued Bulletin No. 1053, describing the products of their electrical department.

THE WILSON ORE TREATING Co., of Denver, have issued their first descriptive catalogue of their Rapid Concentrator.

Ore Feeder Bulletin No. 1 issued by the COLORADO IRON WORKS illustrates and describes the Challenge Ore Feeder manufactured by that company.

STEPHENS-ADAMSON MFG. Co., of Aurora, Ill., are issuing a monthly publication devoted to the description of conveying and transmitting machinery.

Bulletin No. 18 on Magnetic Separators has just been issued by the DINGS ELECTRO-MAGNETIC SEPARATOR Co., of Milwaukee, Wis. It describes in detail this excellent system.

Books Received.

THE ECONOMICS OF RAILROAD CONSTRUCTION, by W. L. Webb. Published by J. Wiley & Sons, New York. This volume of 339 pages deals with the operation, maintenance, and construction of railroads. Questions of working expenses, locomotive and car construction, train resistance, and the operation of heavy trains on grades and curves are discussed in detail. This book is written from the standpoint of the constructing or operating engineer, and only touches on legislation and kindred subjects in so far as they affect questions which must be answered by the railroad engineer. The convenient size and clearness of the book should recommend it to those interested in railroad science.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

PROBABLY nine out of ten ore deposits have some relation to a body of igneous rock. In general, a region free from igneous rocks has a scarcity of ore deposits.

THE proper peripheral speed of hexagonal trommels with fine screens is about 180 ft. per minute. The angle of slope should not exceed 10° from the horizontal.

PUMICE is a glassy lava, which at the time of hardening was so full of steam-filled cavities that it now has a spongy structure and is so light as to float; it is a sort of lava froth.

PATENTED CLAIMS may overlap, and in fact do, in all mining districts, but in making application for patents to claims which lap on ground previously patented, the exact rights desired on the area of intersection must be defined.

IN a deep bin, only a small proportion of the weight of the ore is carried on the bottom, the larger portion—depending upon the depth of the bin—being taken by the sides, where it is resolved into vertical pressure by friction.

ANY lack of parallelism between rolls results in end thrust and the tendency toward wearing away the collars. They should not only be parallel but should also remain truly level. Any departure from these conditions increases the frictional resistance of the machine.

GREENSTONE is a general name applied to certain igneous rocks, usually fine-grained, of a dark green color. They are old rocks geologically and their green color is the result of thorough alteration. They are diabases or diorites, sometimes old andesites, and even basalts.

STRUCTURAL STEEL, if encased in a sound sheet of good concrete, is safe from corrosion for a period longer than a building usually remains undisturbed by changes due to the re-construction of a modern city. Care must be taken, however, that the steel is properly encased in the concrete.

THE adulterants commonly used in the manufacture of rubber are chalk, gypsum, calcined magnesia, asphaltum, barytes, litharge, talc, lampblack, and zinc white. In most cases the adulterants represent more than one-half the 'rubber.' The manufacturers claim that the quality is improved by the addition of certain substances such as zinc white.

PLACER CLAIMS may be taken in twenty-acre tracts, the bounding lines of which must conform with the general system of survey lines established by the Government, but if such survey has not been extended to the district, they must be bounded by true meridian and east and west lines. The survey of coal land is subject to somewhat similar rules.

STANDING WATER in shafts sunk in rocks, as in wells, usually indicates the upper limit of the belt of saturation. But the standing water maintains its uniform level (in the absence of pumping) by flowage through the rocks, compensating the local additions or subtractions. Cracks in the rocks in flooded shafts often become silted up from various causes, and little water flows into the shaft or out of it. The surrounding rocks may become drained while the water-level in the shaft remains practically stationary.

THE Indian coolies imported in Fiji, to work on the sugar plantations, are found to eat large quantities of a decomposed basaltic lava. This rock is so soft as to look like a pink clay. Most of its silica has been removed by weathering, and upon analysis at Sydney it has been ascertained that the earth these coolies eat has a composition close to that of bauxite, a hydrated aluminum oxide.

THE capacity of a crusher of the Blake type depends upon the width of the jaw, the speed at which it is driven, the size to which the ore is crushed, and the character of the ore. The hardest material to crush is soft, talcose, tough stuff, that mashes without breaking. With the jaws set about two inches apart, from 1.25 to 1.5 h.p. per ton of material is required.

THE surveying of mine workings is strictly an economic problem and the surveyor must study it as such. The accuracy attained must be such that the cost in obtaining it and the saving of expense in mining operations through it together effect the maximum of economy. The surveyor bearing this in mind will be neither too careless nor too exact. He will not, for example, close down the mine in order to carry a meridian into it when no important connections are needed, and there are no boundary disputes.

CAMS are made right and left hand because there is some crowding away of the cam from the stamp when in operation; so to equalize this, one battery is made to offset the other, by making the cams right and left. They were so made as early as 1868. In the earlier stamps the crowding away was more marked than it is today. We have no data concerning the origin of right and left hand cams, but presume that it quickly followed the introduction of the round revolving stamp, by C. P. Stanford, about 1853.

THE occurrence of diamonds in a gold conglomerate was determined at Nullagine, in the Pilbarra goldfield of Western Australia. The wear of shoes and dies was abnormally rapid, and, upon investigation, it was proved that the iron was cut by diamonds. A. Gibb Maitland, the State Geologist, ascertained these facts and actually found a number of diamond splinters sticking in the iron. They were portions of small diamonds occurring in the gold-bearing conglomerate, the age of which is at least early Paleozoic, perhaps Cambrian.

THE SURVEYING OF BORE-HOLES. — Bore-holes, whether made by a rotary or a percussion drill, are never perfectly straight, and unless the ground is remarkably homogeneous, are not amenable to any mathematical law. Means have been devised, however, of measuring the strike and dip of a hole at any particular distance from its mouth. The trend of the bore-hole can thus be plotted with some degree of approximation and the position of any particular body or strata struck in the bore-hole determined. One method depends in principle upon the conversion from liquid into jelly, by cooling, of a solution of gelatine, contained in a small vessel, together with a compass needle and a plumb-bob, and of such a shape as to align itself with any part of the hole in which it may be placed. Another instrument takes a photographic record of the position of the compass needle and plumb-bob, after the lapse of such an interval of time as is necessary to place the instrument in proper position and allow the needle and plumb-bob to come to rest. The position of points in any plane stratum, as found by three bore-holes, determines it. If, however, the angle at which a bore-hole cuts this stratum is known, only two bore-holes are necessary, and if the strike and dip of the stratum is known, one bore-hole is sufficient to determine it.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Amalgamation of Copper Ore.

The Editor:

Sir—Although other metallurgical processes have of late taken precedence, there can be no doubt that for many isolated mines, and certain classes of silver ore, the amalgamation process deserves consideration. It may be that an account of my experience will be of service to a brother in the profession. Of literature and theories on the amalgamation of raw silver ore, there is more than can be mastered by a single individual in a lifetime, but with the exception of B. Kroehnke's recent valuable treatise on his process, I do not know of anything which has proved a reliable guide in practical work, and the process has been conducted by empirical routine or experimental practice for centuries, in the same way as other industries, like tanning, baking, brewing, etc. "The remarkable thing being that results were obtained without any positive comprehension of the chemical processes involved and that one has been able to conduct these as if one had been, in part, conscious of the single reactions." How little even the engineering profession understood the process is proved by the fact that coppery low-grade amalgam has been, and is still, frequently considered a bug-bear; at the Comstock, for instance, complicated processes have been devised to dispose of it, when actually in it, they had in hand the most potent agent for the raw amalgamation of silver ore—as will appear from the following. But to come to my proposition.

The ore deposit here is a shear-zone in porphyritic rock occurring along a contact with trachyte; it consists of an irregular network of crevices and seams between the much shattered and shaken-up fragments of, in parts, very decomposed and kaolinized rock. The original silver-bearing ore of the vein, a high-grade gray copper (*fahlerz* or tetrahedrite) containing about 5% pure silver and 30% copper, was in great part turned into an earthy friable product of decomposition, carrying chloride, of a yellowish-green color, and containing frequently a kernel of undecomposed gray copper, so that the sulphide and the decomposed portion of the ore occur largely intimately mixed.

The ore was treated by the Freiberg amalgamation process. In the chloridizing roasting of the silver, volatilization was enormous, about 35%—and this at high or low temperature, long or short duration of process, and whether the salt was added at a later stage of roasting, or originally charged with the ore. Even the introduction of expert roaster hands from the States did not materially change the result. The operation was conducted in 1,000-lb. charges in small hand-roasters, with pine wood as fuel. The chlorination would remain incomplete (85%), and the amalgam resulting was low-grade—nearly half copper. When the roasting was carried far enough to decompose the copper chloride, the silver volatilization would rise to over 50 per cent.

The following scheme, an adaptation of the Kroehnke process, was adopted, with favorable results: The fresh sulphide ore was separated from the decomposed ore by hand sorting, as far as practicable, and then crushed separately in the mill. The decomposed portion passed over concentrating tables (Wilfley) before it reached the settling vat, to extract from it all the sulphide it contained. This concentrate, together with the hand-sorted gray copper ore (representing together about one-fourth to one-third of the entire ore output) were subjected to a

chloridizing roast at a low temperature, with the object not to decompose, but to preserve, the cupric chloride. It gave, after reduction with scrap iron in the barrels, an amalgam containing about four times as much copper as silver. This amalgam was utilized, and at the same time refined, in the treatment—by raw amalgamation—of the decomposed or free-milling ore. This ore was charged with 10% of roasted ore (to insure beyond doubt the presence of silver chloride) and $3\frac{1}{2}$ to 5% salt into barrels, sufficient hot water being added to give it the consistency of mortar; then a certain quantity of the coppery amalgam (dissolved in a few bottles of quicksilver) was added, the amount of it being gauged so that the amalgam produced, when the barrel was discharged, would result in a metal about 900 fine.

The following reactions take place: The metallic copper in the amalgam reduces the silver chloride in the charge, with formation of cuprous chloride, thus:

The cuprous chloride, dissolved in the strong hot brine, acts on the silver sulphide in the charge, with formation of insoluble cuprous sulphide and silver chloride, soluble in the hot brine, thus:

This newly created silver chloride is again reduced by the finely distributed metallic copper and becomes a substitute for it, dissolving in the quicksilver, with the formation of a new quantity of cuprous chloride—according to the first reaction given—until finally almost the entire copper content of the amalgam used has been replaced by the silver extracted from the charge.

It is not difficult to gauge the quantity of coppery amalgam necessary. By retorting a small average sample and deducting from the weight of the retort the silver resulting, the copper is determined with sufficient accuracy to base a calculation as to how many ounces of copper are introduced into the barrel charge by the addition of a certain amount of coppery amalgam. We know the number of ounces of silver in the charge; one-tenth of this we require in copper to remain with the resulting bullion. The quantity of copper necessary for the reactions of the amalgamation process can easily be determined by a laboratory test of a few hundred grams of ore in a bottle, or by adding an evident excess of copper-amalgam to the first barrels of a new lot of ore, when only a part of the copper contained in the charge will be consumed, and the resulting amalgam will yet be high in copper, but will indicate how many ounces of copper the process requires. The coppery amalgam resulting from this experimental charge can easily be refined by adding it to a subsequent charge, in which the copper is sufficiently reduced so that this excess of copper in the added amalgam must be consumed. According to the formula

in which the copper is eliminated in the inert condition of cuprous sulphide, copper would be required only in the proportion of the atomic weights, or 63.3 parts of copper for 107.6 parts of silver present—and the same according to the formula referring to the reduction of the silver-chloride by metallic copper. On account of the excess of about 10% copper that we wish to leave in the resulting bullion and by reason of a number of other reactions, we are compelled to add more copper. The presence of manganese peroxide, for instance, destroys the cuprous chloride according to the formula

under formation of cupric chloride, which violently attacks the fine quicksilver globules, distributed through the charge, coating them with an insoluble film of calo-

mel, which prevents them from uniting again and causes great loss. This can be prevented by the addition of pulverized limestone, CaCO_3 , to the charge, if there be no calcite in the ore which will precipitate the cupric chloride as inert carbonate of copper; still, for each atom of manganese present in the ore charge as peroxide, two atoms of copper in the shape of cupric chloride have been destroyed, and this loss of copper must be provided for by an additional amount of coppery amalgam originally added to the charge. Certain iron salts seem to act in a similar way.

Consequently, it is advisable to crush the ore in large lots, well mixed, so that after the amount of copper necessary has been determined in the first few barrels, the treatment for the entire lot is definitely known. The advantages of this method of working are evident: Roasting is reduced to less than one-third of the former amount, being restricted solely to the sulphide. The high silver losses by volatilization are avoided; these had been due to the roasting of the natural chlorides in the decomposed ores in the presence of sulphide and sulph-antimonide. The quicksilver in the barrel charge is completely protected against being attacked and powdered by chlorination, through the stronger electro-positive copper dissolved in it and present up to the end of the amalgamation reactions. The end is easily determined by examining the physical characteristics of a sample of the amalgam, washed from a spoonful taken out of the charge. When sufficient copper had been added originally and this has been substituted by silver, the ore is extracted and the amalgam becomes reasonably pure.

It would seem that in the Washoe pan process the high-priced copper sulphate added must form—with the salt—cupric chloride, which, reduced by attacking the generally very costly (at the mines) iron castings, gives a corresponding amount of expensive copper-amalgam, to which the reaction of the process is partly due. This reaction must, however, remain incomplete, since the cuprous chloride formed by the reduction of the silver-chloride—and which is necessary for the transformation of the silver-sulphide into chloride—cannot maintain itself and fill its mission completely, but must be reduced by the iron parts of the pan to metallic copper. Hence coppery amalgam and low extraction. From this point of view amalgamation in an iron vessel appears radically at fault, and the substitution of a copper vessel or pan, which, of course, could only serve as an amalgamating and not as a grinding apparatus, would seem advisable.

What Is Slime?

The Editor:

SIR—Slime is now receiving so much attention and is so conspicuous a feature in ore treatment that there seems to be a growing disposition to designate some measure of fineness which shall define it and receive general recognition.

We know slime now as a condition of pulp that requires attention more or less different from that given to sand. In my own experience I have found that slime, as it appears to us, is not altogether a matter of extreme fineness, but the manner of creating it is also a factor. Aeration in process of crushing greatly increases the visual evidence of slime.

Many years ago I had been crushing an ore with stamps, using but little water, and the pulp went largely to slime, although a medium screen was used. Near-by a large slow-traveling Chilean mill was installed and began crushing on the same ore. Instead of screens they

used float overflow, about 18 in. above the die. To my surprise, there was no evidence of slime in the vat which received the pulp, the water flowing away from it clear. In this case there was no possible contact of air with the pulp at, or after, its crushing, as the stream had but a gentle flow (without falling) from the mill to the tank. For concentration, it is plain that aeration of pulp is not desirable.

The Best Shape for a Shaft.

The Editor:

SIR—I have followed your discussion on 'The best shape for a shaft' with much interest. It is sometimes a help in matters of this kind to know what others are actually doing, and for this reason I give the following figures of work now being carried on:

At Butte, the standard size for a hoisting compartment is four feet by four feet six inches, that means that all local cars, cages, chairs, skips, etc., are made to fit this size of shaft-compartment, and thus, if extras or renewals are needed, they can be bought to fit, and will fit. The guides are on the four-foot dimension, of course, so that these usually take off four inches on each side, leaving the hoist-compartments each 40 in. in the clear, by 54 inches. I am at present sinking two shafts at Butte, each of three compartments; one has two standard compartments and a pump and manway four feet six by five feet, the other and newer shaft is standard in hoisting section but has a pump compartment 4 ft. 6 in. by 7 ft. in the clear. The last dimension we consider ample for pumps to handle up to 1,200 or 1,500 gal. of water per minute, and also for what is locally known as a 'chippy' cage, that is a smaller cage actuated by small engine on the surface and devoted to the uses of the pumpmen, for handling pipe, pumps, and all incidental work, such as the foremen and shift-bosses in their rounds, thus relieving the main hoisting engines of much petty work. This shaft is timbered with 12 by 12 in. Oregon pine, and the compartments are separated by 10 by 14 in. timbers which carry the guides for the cages and skips.

From the figures quoted it is seen that the outside dimensions of the hole necessary to contain these timbers is 18 ft. 8 in. by 6 ft. 6 in., and of course such a shaft when broken will be nearly 20 feet by seven feet. We expect to carry this shaft down to not less than 1,500 ft., and probably much deeper than that, and consider it ample to allow us to hoist not less than 1,000 tons per day, should we be lucky enough to have that much to hoist steadily. With the big hoisting skips in use at Butte, pockets cut below principal levels and facilities for handling materials above, there is no trouble in doing such a tonnage through this shaft.

At one of my shafts in Butte I hoisted from 600 to 900 tons in this way through such compartments, and the engine was only 18.5% of its time hoisting ore, the rest was taken up with men, timber, waste, etc., or it was standing! It is needless to state what form of shaft I would advocate.

JAS. W. NEILL.

Pasadena, September 25.

HUXLEY'S purpose in life, as he expressed it himself, was: "To promote the increase of natural knowledge and to forward the application of scientific methods of investigation to all the problems of life to the best of my ability, in the conviction that there is no alleviation for the sufferings of mankind except veracity of thought and action, and the resolute facing of the world as it is when the garment of make-believe, by which pious hands have hidden its uglier features, is stripped off."

Prospecting Dredging Ground.

Written for the MINING AND SCIENTIFIC PRESS
BY D'ARCY WEATHERBE.

In considering the prospective value of dredging ground there are many conditions to be taken into account besides its actual gold content; it is like all other classes of mines in this respect. As a prominent mining engineer recently said: "Each mine is a law unto itself." Likewise each dredging scheme must be considered strictly on its own merits before deciding on the methods and machinery to be used. Failure to recognize the specific conditions affecting a property, in calculating the means and cost of working it, has entailed the loss of large amounts of money. Misrepresentation and 'salt-

Prospecting Drill and Recovery Process on the Yuba.

ing,' too, have played an important part in dredging as in other kinds of mining. Besides the amount of gold and the manner of its distribution, the following points must not be overlooked:

1. Characteristics of the gravel, as to clay, hardness, cementing, size of boulders, etc.
2. Depth to bedrock; the character and contour of the rock.
3. Permanent or variable water-level, and available water supply under head or otherwise.
4. Costs of power, labor, transportation, and supplies.
5. Another consideration, not seriously affecting dredging in the State of California, but to be taken into account in many other localities, is the climate.

The methods of determining the factors mentioned are by sinking shafts, by drilling, and by actual test with dredge. Many diverse opinions have been expressed as to the relative value of each method, but undoubtedly the most practicable is the shaft. Water, however, is a serious drawback to prospecting by shaft and therefore

drilling is more common. The Keystone drill No. 3 boring a hole of six-inch diameter is generally used in the Sacramento valley and it costs about \$1,700. Theoretically, provided that all of the core drilled (and no more) is recovered, 16 in. should be drilled in depth for every cubic foot of core produced. It will be found that this result varies from that obtained on the assumption that the diameter of the core is equal to the diameter of the outside of the shoe. The sand-pump is a hollow-steel cylinder 8 ft. long and 4 in. diam., with a valve at the bottom and a closely fitting plunger; on each side, near the top, it has an oval orifice to allow the pulp to be washed out. There are several methods of treatment, and the general practice is the same though the methods of keeping records and estimating results differ slightly. The apparatus used includes a sluice-box, 16 by 12 in. and 10 ft. long, with holes at the lower end for allowing flow into a four compartment settling-tank, another settling-tank, and an ordinary rocker with several pans and tubs. A bucket is placed in the sluice and the contents of the pump are washed into this, each foot being treated separately. The overflow runs off into the settling-tank. The content of the bucket is panned into a tub. The number and size of the 'colors' or particles of gold in each pan are estimated by eye and the result of each foot is noted in the log-book, the colors being classed in three sizes. The colors and black sand from each pan are kept separately; the former are segregated for each foot and then amalgamated. The gold is separated by nitric acid, washed, dried, annealed, and weighed, the resulting buttons from each hole being assayed for fineness. The surplus contents of the pannings caught in the tub are passed through the rocker, the concentrate being re-rocker. The overflow runs into another settling-tank and the contents of the two settling-tanks are roughly dried and measured, the computed yardage being thus checked.

Another method is as follows: The material from the hand-pump is received in a pan held in a sluice-trough similar to that mentioned above. The slime is allowed to flow away and the coarsest material is panned off in the tank. The finer portion of the material in the pan is panned over a large metal tub. The estimation of 'colors' is made in the usual manner, and everything in tub and trough is then passed over a rocker.

Often the rich material in the interstices of the bed-rock or a rich seam will continue to be pumped into the hole, giving higher pannings than are warranted. To prevent this, when within a foot or so of the bottom, the results are panned as usual and from the foot just above and below bedrock the concentrate is caught in separate pans and if the results appear unduly high they are disregarded. All this is noted in the log-book, as well as the character and amount of gold content, other particulars relating to the character of the gravel.

In one instance I observed an ingenious method of preventing salting. The work was being done on single shift, and on leaving for the night two panfuls of barren tailing were dropped down the hole. The heavy bit with rope attached was then lowered into the hole and the iron blocks were put on. To move these it would have been necessary to re-fire the boiler. In the morning the blocks were removed and the rope and bit washed into the hole and pounded to knock off any 'salt' (gold flakes) that might have adhered to them on being dropped down. The pans and sluice, etc., were thoroughly washed and the barren tailing at the bottom was tested. It might be a safer plan to keep a watchman on the spot.

A clever case of salting the drillings occurred recently at Oroville. The 'salter' mixed some finely divided gold with pipe-clay; he became so adroit that he could mark a piece of casing on the inside so that the streak would

contain a given number of cents per cubic yard to be drilled. In case the driller noticed the marks at all, he would simply think that they were initials or shop numbers, and during the process of drilling, the streak with its fine gold was washed into the pump and unwittingly recovered with the gold in the gravel.

In connection with salting, several cases were related where the drillers wilfully produced (at the instance of their employer, it is said) misleading records by the following method: The bulk of the gold content was

holes at long intervals and then closer together if favorable results are indicated.

The cost of drilling differs with the conditions, but it may be said that the price per foot will vary between \$1 and \$3.75 per foot—a wide range. In one case at Oroville 13 holes were put down at a cost of \$3.48 per ft., and in the same district at another property seven holes cost \$2.40 per ft. Some contract work at Oroville was done for \$2.50 per ft. The following recent examples of costs

and speed cover a large area, and will give a practical idea of the variation: On the Yuba, five holes were drilled to an average depth of 93 ft. at an average cost of \$3.85 per ft. The work was done during the winter rains and the roads were extremely heavy—freighting was difficult, transportation charges excessive, and there was great delay in having repairs made at Marysville (the nearest point), the fixed charges having to be sustained all the time. Moreover the work had to be finished within a time limit, so as to secure results before an option on the property expired.

In the southern part of the Oroville district 50 holes were put down averaging 35 ft. each and two drills were employed working simultaneously. The cost in this case averaged the

extremely low price of 97c. per ft. The work was done in summer and all conditions, including soft ground, were most favorable. Water was close at hand and the fact that both drills ran under the same

Rocker and Second Settling Vat at Central Dredging Company's Drilling Plant.

known to lie in a stratum three feet thick and between 17 and 21 ft. from surface; each hole was drilled to about 30 ft., or 10 ft. deeper than was necessary. To illustrate the result we will assume that each of the three feet between 17 and 21 ft. contained 60c. per cu. yd. and the cost of drilling was seven cents. Thus the whole ground necessary to be dredged (20 ft. deep) would average nine cents per yard, leaving a profit of three cents per yard worked. The crafty party who attempted to wreck the negotiations for a fair sale, handed in his report, giving the depth of the ground as 30 ft., and the average yield per yard as six cents. Taking the vendor's admitted cost of working (seven cents), there was an apparent loss of one cent per yard; and so the sale was declared off.

A great deal has been said about the extreme care necessary in making estimates from drill-records. At the best, the method is but an approximation and the accuracy with which it is done should bear an exact ratio to the care taken in measuring the bank and calculating the cubic content dredged each month; otherwise, the results are not only misleading, but useless.

As to the number of holes necessary to test the ground, this also is arbitrary. If the gold is known to be evenly distributed, the tract should be divided into five to ten acre squares. A flag at the centres of these marks the site of the hole. If the gold is in narrowing or widening channels, the ground should be first crossed by series of

Delivery Vat, First Settling Vat, and Sand-Pump.

management reduced expenses. The labor included 1 foreman, 2 drillers, 2 helpers, 1 panner, 1 two-horse team and 1 teamster; the last also acted as water carrier.

At Oroville nine holes were put down about June, 1904, and totaled 258 ft. in depth. One machine was used on single shift and 33 days were employed in the work with four days more for moving.

With regard to the ratio of recovery between dredging and drilling much, of course, depends on the method and care employed, the relative efficiency of the gold-saving appliances and the manner in which the clean-up is accomplished. Most experienced operators contend that

however carefully the operation is carried out (within the practical economic limits) and using the best of gold-saving appliances the results by drilling can never approximate the work of sampling and estimating an orebody underground. It might be supposed that by using an arbitrary method of (over or under) estimating the drilling results, a fair idea of the probable recoverable value might be arrived at and if the results bore a consistent relation (greater or less) to the recovery, this would be an effective method, but such is unfortunately not the case in practice. The ratios are quite irregular and results vary both above and below the returns from prospecting. Only one general rule seems to hold, and its application is found to be generally true, namely, that when very high results—70c. to \$3 say—are got by drill, the recovery from that place is sure to be lower. Likewise it is true in practice, that ground giving very low results from the drill, say from 1 to 5 or 6c., generally dredges considerably higher. Some experienced operators go so far as to say that drilling is practically useless except as a means of ascertaining whether gold is actually present in the ground or not. On the other hand at Folsom, where several thousand holes have been put down and the most careful records kept, it is asserted positively that an average approximating about 90% of the gold shown by drilling has consistently been obtained in dredging. Be that as it may, when it is explained that roughly a drill-sample will only represent something like $\frac{1}{200,000}$ to $\frac{1}{1,000,000}$ of the body of material to be worked while in sampling a mine probably from $\frac{1}{2,500}$ to $\frac{1}{10,000}$ is taken of the orebody (which is not, as a rule, less homogeneous than the gravel beds), there should be at least a proportionate difference in the working results. Moreover, the method of estimation and selection cannot be compared for accuracy. The following authentic cases are extremely interesting in this connection: In front of the Boston and California dredge No. 1, 22 holes were put down in one acre, and the results showed that the ground contained 60c. per cu. yd. When this particular acre was dredged, just 30c. per cu. yd. was recovered. In another instance, 25 holes were put down on one acre and the dredge recovered 95% of the estimated amount. On the Delancy tract, the results of dredging recovery came very close to the drill-estimate, the latter being very carefully done. Of course, the closer together the holes are put down and the more of them there are on a given tract, the closer the general result for the whole tract should come to the actual recovery; if the work is properly done, a fairly accurate idea of the value of the property may be obtained.

For the 12 months ending December, 1903, the *Biggs No. 1** dredge of the Oroville Gold Dredging & Exploration Co., Ltd., worked 474,610 cu. yd., which, according to the estimate from prospecting, should have yielded 11.40c., the total recovery averaged only 8.45c., or 76% of the prospect value. The same dredge for the following 12 months of 1904 dredged 493,150 cu. yd., which yielded 12.32c. per cu. yd., whereas the prospect value of the area worked showed from the drilling tests an average content of 16.64c. per cu. yd., in other words, a recovery was obtained of about 74% of the estimated value by drilling. The following details of the above cases show that the ratios of recovery in cases of ground dredged after one or two drillings vary greatly, while the total average for the year appears to maintain a fairly uniform relation.

In another district in the Sacramento valley for the three months of March, April, and May, 1906, a certain dredge recovered an average of 25c. per cu. yd., where

prospecting by drill had only indicated 18c. per cubic yard.

Naturally, careful shaft-sinking is a more satisfactory method of testing; it ascertains both the gold contents and the nature of the ground far more efficiently and thoroughly, but the cost is sometimes prohibitive in wet ground. Otherwise it costs less than drilling. The so-called China shaft is the method usually employed and unless one has seen the work, one wonders how it was ever accomplished by hand. Probably workmen of no other nationality would do the work or, in fact, could work in such a narrow compass.

The shafts are sunk, circular in section, three feet in diameter, and the work is done by Chinamen. Two men will do from five to eight feet per day, and at Oroville the contract cost is \$1 per foot. Washing and estimating content will cost about 30c. per day more. These costs are for all work above water level. Below that level special arrangements have to be made and it is often altogether impracticable because 'John' is decidedly averse to working while water is being hoisted over his head, and little is he to be blamed for his objection. In more than one case he has sunk such shafts where it is dry, to depths of 40 ft. and over. The whole area of a certain property at Oroville could have been efficiently and cheaply tested in this manner, but for some inscrutable reason drilling was resorted to after a short period. Shaft-sinking on one property at Folsom cost \$1 per foot including panning, etc., and an average of nine feet per day was accomplished.

Both at Oroville and Folsom most of the ground now being worked by dredge was all worked over years ago by pan, rocker, and sluice during the early days. As the grade of the gravel got lower, the white men left and Chinamen took their places and the ground was re-worked. In the dry season it is probable that these old shafts and drifts in many places reached the present bottom as shown by the timbers and portions of wing-dams that are encountered by the dredges and drills every day—much to the operator's disgust. Although not thorough, this work was so general and the district was so carefully exploited that today it is said that ground where old workings are not found is generally poor, and actual values of 15c. per pan and over have been obtained from some of the old tailing beds. These abandoned workings, when encountered by the prospect drill-holes, however, form a menace which often vitiates entirely the result of the hole, as it is impossible to say from what amount of gravel the results are produced. The following authentic record from some recent prospect holes at Oroville show how variable is the distribution of the gold. In some cases it seems to lie in well-defined streaks and elsewhere it is disseminated through almost every foot of the ground to be worked.

AN iron sickle, found by Belzoni under the feet of one of the sphinxes at Karnak, is deposited in the British Museum and proves that the smith's art was practiced at about 600 B. C. In 1837 a fragment of a wrought iron tool was found in blasting operations in the Great Pyramid. This piece of iron, nearly 5,000 years old, is also preserved in the British Museum. Analysis showed it to contain a small proportion of nickel; but as it also contained combined carbon it was not of meteoric origin.

THE constant widening of the intellectual field has indefinitely extended the range of that especially human faculty of looking before and after, which adds to the fleeting present those old and new worlds of the past and the future, wherein men dwell the more, the higher their culture.

*The *Biggs No. 1* is now *Exploration No. 1*.

The Geological Distribution of Gold.

By T. A. RICKARD.

*When gold was discovered at Ballarat, in Australia, there was a great rush of adventurers to the diggings. It is recorded that in November, 1851, Henry La Trobe, the first governor of the new colony of Victoria, paid an official visit to the goldfield. As he rode among the sluice-boxes and pits of the miners, he was fascinated by the glamor of the search for gold, and became keenly interested in the manner of its occurrence. Finally, finding himself talking to an old Cornishman of more than average intelligence, the Governor said: "And from where do you think the gold comes? The old miner leaned on his shovel and scratched his head, as he replied: "Where it is, there it is; and where it aint, there be I." For fifty-five years that reply has been echoed from many a prospect hole on both sides of the equator; it has been received as the last word of geological vision and the epitome of mining realization. The story is founded on fact and it is confirmed by individual experience, and yet it does but serve to emphasize the advance which has been made during half a century of investigation. The jibe at geology which makes other versions of this original incident pass current among those that seek mineral wealth, is not warranted today. We have emerged from the uncertain shadows of the dawn; geology and mining face each other now with a better understanding than in the golden age of Australian and Californian discovery.

The practical aid which geology gives is a comparatively recent development of the application of science to industry. When geology was yet an infant, looking at the world from out of the cradle of Lyell's 'Principles,' mining had already attained a venerable age. The young science offered to guide the old blind deliver of the rocks and, in the effort made several childish mistakes, which are still remembered in the days of its maturity.

Sir Roderick Murchison made the chief of these blunders that at one time estranged the geologist from the miner. The story of an error made by a man of such acknowledged talent should not merely provoke derision now that we have the ampler light of a fuller day and, possessing facts which were unknown to him, can thus, as it were, write last year's almanac, but it should furnish a striking warning against confounding a coincidence with a consequence and being led thereby to frame a wide generalization upon a narrow basis. It will be remembered that in the course of his famous elaboration of the Silurian system he made a study of the Ural mountains, including the goldfields of that region, which in the first half of the last century were of far greater importance than they are now. On his return from Russia, the results of his investigations appeared in several papers, which were published during 1841 and the succeeding years. In 1844 he drew attention to the similarity existing between the gold-bearing rocks of the Urals and certain specimens from Australia, sent to him by his friend Count Strzelecki¹. The Ural rocks were highly altered crystalline schists, while those from Australia were silicious slates. Both were of Lower Silurian age, as was proved by fossils and correlation. Murchison noted the resemblance between these rocks and remarked that the Australian specimens exhibited quartz, although no gold had as yet been found. Furthermore, he drew attention to the similarity in the trend of the Australian cordillera and his beloved Urals. He really knew nothing about the geological structure of Australia²; nevertheless, the analogies which he detected led him to suggest

that the Blue Mountains in New South Wales might also contain gold-bearing veins. In 1846 he learned that specimens of gold ore had actually been found there, and he then advised Cornish miners to go to Australia to search for gold³. In the meanwhile, he had given out a statement, based on his studies in Russia, that gold would be found to be exclusively confined to the Paleozoic rocks, and especially to the Lower Silurian. Therefore, when, in 1851, it was announced that wonderful discoveries of gold had been made in Victoria amid beds of slate and sandstone belonging to this geological period, they were heralded as the confirmation of a scientific dictum, and Murchison was generally congratulated on his successful prediction. He congratulated himself. In the third edition of 'Siluria,' published in 1859, the "inductive reasoning" which led to his hypothesis is repeated, and he says: "My chief article of belief has now proved to be true—that is, that the rocks which are most auriferous are of Silurian age." The unfortunate generalization is again worded thus: "The Paleozoic accumulations * * * particularly the Lower Silurian * * * are the chief sources whence gold has been or is derived."⁴

Australia indeed appeared to corroborate this. It was not until 1864, when the results of the work of the Geological Survey of California, under Whitney, were published, that the Silurian formation lost a pre-eminence to which it was never entitled. The gold-bearing rocks of California were found to belong to the Jurassic. Murchison's hypothesis was confounded. It was a fallacy which the later development of gold-mining districts in other parts of the globe has shattered into as many fragments as there are subdivisions of geological time.

The following tabulated statement shows at a glance that the chief goldfields of the world are scattered through

GEOLOGICAL DISTRIBUTION OF GOLD AS ILLUSTRATED BY THE PRINCIPAL MINING DISTRICTS OF THE WORLD.

Period	Rock	District	Region
Quaternary	Andesite	Monte Cristo	Washington
Tertiary	Eruptive	Cripple Creek	Colorado
Cretaceous	Sandstone	Verespatak	Transylvania
Jurassic	Amphibolite Schist	Mariposa	California
Triassic	Limestone	Raibai	Carinthia
Permian	Conglomerate	Stupna	Bohemia
Carboniferous	Shale	Gympie	Queensland
Devonian	Conglomerate	Witwatersrand	Transvaal
Silurian	Slate and Sandstone	Bendigo	Victoria
Cambrian	Slate and Quartzite	Waverley	Nova Scotia
Algonkian	Schist	Homestake	South Dakota
Archean	Granite and Schist	Lake of the Woods	Ontario

the entire sequence of geological strata, from the Archean to the Tertiary. The Lower Silurian of the Urals is now scarcely worth mentioning, the gold production of that region having dwindled to insignificance. Since Murchison's day the geographical centre of Russia's gold production has shifted steadily eastward. It was once at Ekaterinburg, in the Urals; it passed to the Yenesei, and then to the Olekma. Today the chief gold region is that which is drained by the Amoor and its tributaries. The goldfields of Victoria, in Australia, also refuse, now, to be identified any longer with Murchison's blunder, several of the best districts⁵ in that colony having been developed in the Upper Silurian, as distinguished from the prevailing Lower Silurian of the first discovered gold-veins at Ballarat and Bendigo. Newer mining regions, scattered all over the globe, afford testimony which denies the supposed relation between gold-deposits and the age of the rock enclosing them. Although numerous rich districts occur in igneous formations of the Tertiary period, no important goldfield of the present day is identified with sedimentary rocks later than the Cretaceous; nevertheless, to make the testimony complete, it can be stated

³Trans. Royal Geographical Society of Cornwall, 1846, p. 324.

⁴'Siluria,' 3rd Edition, p. 474.

⁵For example, the Walthalla district, in Gippsland. The principal mine is the celebrated Long Tunnel, which has attained a depth of 2,300 ft. from the surface and has produced more than 23 tons of gold. The mining districts of Wood's Point, Alexandra, and Mt. Wills may also be cited.

*A paper read before the American Mining Congress, at Denver.

²Life of Sir Roderick K. Murchison, by Archibald Geikie, Vol. II p. 134.

that a conglomerate⁶ of undoubted Tertiary age, covering an extensive area in southwestern Colorado, contains gold-veins, which have been mined at a profit. If eruptive rocks be included, we have the testimony of J. E. Spurr that the gold veins of Monte Cristo, in the State of Washington, occur in andesite and tonalite of Pleistocene or Quaternary age,⁸ and at Steamboat Springs, Nevada, gold has been detected⁹ in cracks traversing the sinter around a thermal vent; this rock can therefore be labeled Recent. The Laurentian granitoid-gneiss of western Ontario is traversed by important gold-bearing lodes⁷. Therefore, the record of the rocks, in regard to their association with the occurrence of gold, is unbroken throughout the main divisions of geological time.

If geological authorities have made blunders in the application of theories to actual mining, it is only fair to acknowledge that practical mining captains have erred no less. Their errors, like those of greater men, have also sprung from that little knowledge which is proverbially dangerous. Thus, possessing, as a rule, no wide geological training, they avoid the pitfalls awaiting them in that direction only to get mired among hasty deductions based on the recognition of the physical peculiarities of rocks. For instance, in most mining districts the idea prevails among mining men that a particular rock is favorable to the occurrence of gold and silver; this may be true indeed of any one especial locality, but I have commonly found that mining men apply their restricted experience to other, and quite dissimilar, districts by the use of sweeping generalizations which are based on such local knowledge alone. Thus, in South Africa, granite is looked upon askance as being extremely unlikely to contain profitable gold-veins, and those who have had their experience in the Transvaal are apt to be pessimists when they find themselves amid a granitic environment. In Colorado, slate and schist are not characteristic of successful mining, therefore these rocks are unfavorably regarded, while granite is accepted as a likely terrain. In California, the great gold-mining belt is in slate and schist, while on the other hand the granite of the Sierra Nevada has been less successfully explored, therefore, 'black slate' is the desired evidence of probable richness. A mining district in India was recently condemned for the reason that the prevailing rock was a hornblende schist and yet the productive Kolar goldfield is situated amid rocks of this very kind. Limestone is regarded in Colorado as the depository of enormous orebodies, such as have made Leadville and Aspen famous, but in British Columbia it is considered, by many, to suggest small and erratic occurrences of ore, much less desirable than the supposedly persistent type of vein that occupies a fault-fracture.

These generalizations have delayed the discovery of several mining regions which are now highly productive. Experienced Australian miners passed by the conglomerate lodes of the Witwatersrand because the conditions were beyond their ken, which was largely confined to the slate and sandstone of such districts as Bendigo and Ballarat. The Cornishmen who had worked successfully for tin in their native land and for gold in Victoria failed to recognize the possibilities of Broken Hill. When Cripple Creek was first visited by old mine-managers from the Gilpin and Leadville districts, an unfavorable verdict was pronounced by men who were more familiar with granite and limestone, as ore-bearing rocks, than with an

intricate series of new volcanics. In the case of this, the richest gold-producing district in North America, I can vouch for the fact that the men of science proved far better prophets than those who were versed in the actual practice of mining; the latter supposed that the conditions at Cripple Creek were unique, a supposition which disregarded the fact that the larger number of the richest veins in the San Juan region, in the same State, were in a rock of almost identical age and composition, and, to go farther afield, that there were at least two foreign localities, Transylvania and New Zealand, where a similar andesite-breccia had proved to be the envelope to rich lodes of gold and silver ore.

Instances of similar blunders might be multiplied. But it is not necessary. Are they not written in the chronicles which tell the story of mining discovery the world over? Besides, it will serve no useful purpose to deal in destructive criticism only; the recital of the foregoing facts is intended to clear the ground before offering something, be it only a rough stone or two, wherewith to build a permanent structure. We have discarded the old notions that connected the occurrence of gold with any special stratigraphic horizon or a particular petrographic encasement, in other words, any one formation or any one rock; then let us ask if there be not some other generalization that avails us in the search for the metal. Is it all without rhyme or reason, is the gold as much in sea water as in syenite, in the youngest and in the oldest rock, in high mountains and in flat deserts? The answer is that the occurrence of ore depends neither on the geological age nor the petrography of a district, but upon local structural conditions and upon an eruptive activity often identified with specific periods in geological time. To come to particulars, there is plenty of evidence, which I have collected during the last ten years and which is too bulky to be offered on this occasion, that the eruptive rocks closely associated with the deposits of the precious metals in Colorado are of early Tertiary age; they are post-Cretaceous and pre-Pliocene. The close of the Cretaceous period in Colorado was one of mountain-making, it was a time of great orographic movement, that is, the main ranges of the Rocky Mountains underwent slow uplift and, in the process, their constituent strata were folded and buckled, were crushed and fractured. Accompanying this disturbance, possibly the cause of it, more probably a manifestation of deeper unrest, there came a tremendous outpouring of lava. Some of it was emitted violently from orifices so as to form volcanoes, as at Cripple Creek and Silver Cliff, some of it fell into large areas of fresh water and consolidated into nearly horizontal deposits of breccia, as in the San Juan, and another portion remained in the shape of dikes, sheets, and cores of igneous rock traversing the older formations in diverse directions and shapes, as at Leadville and in Gilpin. This epoch of volcanic ruction lasted long, it was intense during early Eocene time, and again at the close of that period, continuing into the Miocene; and as the vulcanism died out, it had its sequel in a longer era of thermal activity, that is, the volcanic heat no longer expressed itself in the explosive escape of steam and rock fragments, but was manifested in the heating of underground waters and in the quickening of their solvent action, their circulation, and the precipitation of their contents in the approach to surface. Wherever we know the age of the eruptive rocks in contact with, or related to, the occurrence of gold (and silver) in Colorado, we find them to be post-Cretaceous; sometimes we can ascertain definitively that they are Eocene or Miocene. This is true of the quartz-felsite of Leadville and Aspen, the phonolite of Cripple Creek, the andesite of Ouray and Telluride, the porphyrite of Rico, the rhyolite of Silver Cliff, Summitville, and Creede, the diorite of Ophir and

⁶The San Miguel formation of the Telluride district.

⁷For example, in the Lake of the Woods district. The Sultana mine may be instanced. It is situated near the contact of the Laurentian granitoid-gneiss and the overlying Keewatin schists, the latter being considered to be Algonkian, or intermediate between the Cambrian and the Laurentian basal complex.

Mining for Gold in Jurassic Rocks in California.

Mining for Gold in Cambrian Rocks in Nova Scotia.

La Plata Mts., and when we come to the mining districts in unstratified rocks, such as the granitoid gneiss of Boulder, Gilpin, and Clear Creek, we find a quartz-andesite in the localities where profitable mining is being done; and while we cannot determine the age of that intrusive, for lack of younger rocks that it penetrates, we find that it bears a close petrographic analogy to the quartz-felsite or porphyry of Leadville, which does (as at Breckenridge) penetrate the Cretaceous. I know of no eruptive affiliated with profitable gold or silver ore deposits in Colorado that is geologically older than early Tertiary. In Colorado therefore a particular period of vulcanism and its sequelæ of thermal activity are identified with the formation of the fractures and the deposition of the ore, respectively, that have given us valuable mines.

In other regions, it is likely that other periods were beneficial to the miner. It would be an old sort of blunder to conclude that the particular conditions observed in Colorado must have world-wide application. No blanket theory will do. To illustrate; in eastern Australia (in New South Wales and Queensland) the great epoch of eruptive activity was much earlier than in Colorado, namely, at the close of the Carboniferous period; that was Australia's time of mountain building, the Carboniferous strata being often found standing vertical underneath the horizontal beds of the Permian, thus constituting the greatest unconformity in Australian geology. This period is identified with the coal measures and, strange as it may seem to us in America, with gold deposition, for in many portions of the basal beds of the Permo-Carboniferous series alluvial gold is found, sometimes in such quantity as to be worth mining. The rock characteristic of this eruptive period and associated with the gold deposits of the eastern part of Australia is a granodiorite, sometimes differentiated as quartz-felsite. There is no evidence of regional eruption in eastern Australia later than the Carboniferous; there are basic lavas belonging to late Cretaceous and early Tertiary time, but they are local and no orebodies are associated with them.* At Bendigo and Ballarat, of course, in southern Australia, we have Tertiary basaltic dikes in close association with the gold veins, but there is evidence suggesting that the original lode formation was started at the time when the neighboring granite was extruded, and that was at the close of the Silurian period and before the Devonian sediments were laid down; there is also good reason to believe that to the Tertiary vulcanism we owe the resolution and concentration of the gold in the orebodies valuable to man, in Victoria. That factor—of later mineralization and concentration—is less apparent in New South Wales, which has no goldfields comparable to Bendigo and Ballarat. In the Transvaal the conglomerate is of Devonian age, but the dikes that penetrate it and that have influenced the distribution of the profitable ore are of Tertiary age.

The subject is immensely wide—wide as the world—and it is difficult to compress an intelligent treatment of it within reasonable limits. Deposits of gold ore occur in rocks of every age and in rock of every kind. The metal was deposited later than the encasing rock and it is likely that since it was so deposited it has been subject to constant solution and precipitation, by which it has been re-distributed and concentrated. The first deposition, the time when it was brought from below the zone of rock fracture to the place of precipitation, was associated with a thermal activity following upon regional movements and volcanic eruptions; that time of first formation may have been late or early, in the Cambrian or the Cre-

taceous of geological history. But once so deposited, it became at once the sport of the chemical waters that find a passage both from the surface and from the deep. These may have effected no noteworthy re-distribution of the gold along the rock-fractures where the ore lies; such was the case apparently in New South Wales, for the gold deposited in Carboniferous time has not traveled far or been concentrated much. In other regions, for example in Colorado, a much later era of fracturing and vulcanism has afforded the intense thermal activity that led to the formation of new rich veins and lodës, or caused the re-distribution and concentration of the gold in older and poorer deposits.

After all, it is only the concentrations of gold that interest us as miners, there is gold everywhere, even in sea water, but what we as miners want to know is where is there ore rich enough to more than pay the cost of exploitation and extraction. The old miner scratched his head and said, "Where it is, there it is; and where it aint, there be I." The rest of us have often been where it was not and we sympathize with him, but yet not without hope, for we know some of the causes that tended to concentrate the gold in one place and to impoverish the vein in another. The world that lies underground may be dark and yet the safety lamp of science can be depended upon for some light, and as we learn how to pass the dangerous places of uncertain knowledge, we shall at last be able to use without danger the naked illumination of substantiated theory.

DIAZ ON LABOR UNIONS.—In his message to the Mexican Congress, delivered on the afternoon of September 16, President Diaz referred to the recent trouble in Cananea and followed the reference with a statement of the attitude of the Mexican Government toward labor unions. He said: Recently there have been other movements of workingmen, principally partial strikes, the most important having been those instituted by mechanics of the Mexican Central railroad, who, in considerable numbers, abandoned various shops of the company. These movements they carried out in an entirely peaceful manner, limiting themselves to suspending work, with a view to securing the establishment of certain determined conditions by the management. Being within their rights, they have been respected by the authorities, who were directed to see that the public order was not disturbed and that other crimes were not committed, and to make known their firm intention of repressing with all energy whatever disturbances might be incited.

There has been observed on the part of the workingman a marked tendency to organize union and mutual corporations for the purpose of acquiring the strength which they consider necessary for imposing conditions on their employers. The executive is willing to recognize the right of the working classes to associate themselves, provided that they respect all legitimate interests, as much those of the capitalists as those of the workingmen themselves. If the right to refuse to work under determined conditions is respected, the right of others who may accept the conditions to work under them is no less to be respected. Both are the necessary and obligatory accompaniments of individual liberty. The executive, who is resolved to respect all rights and to preserve undisturbed the public order, hopes, from the good sense and patriotism of the capitalists and of the Mexican workmen, that each may always consider the rights of the other, a condition which will redound to their welfare and to that of the country at large.

TIN is usually found in, or in relation to, granite, especially the mica-quartz variety, called greissen. It is often pseudomorphic after feldspar.

*To Mr. Thomas W. Edgeworth David, professor of geology in the University of Sydney, I am indebted for these facts.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

An action in ejectment lies to recover the possession of a mine where the lease contained a clause providing for a forfeiture for non-compliance by the lessee with the conditions of the lease, on proof that the conditions were broken.

Brooks v. Gaffin, (Mo.), 95 S. W., 418.

The owner of mining ground on a stream, having superior rights to the use of the water, may enjoin a lower proprietor from maintaining a dam in such manner as to back the water up and thereby prevent such upper owner from discharging the debris from his mine into the stream, thereby interfering with the operation of his mine.

Kane v. Littlefield, (Or.), 86 Pac., 544.

The purchaser of a mine assumed to pay certain claims as a part of the purchase price, out of the first profits received from the sale of ore; some ore was extracted and the mine sold. It was held that the purchaser could not escape liability by selling the mine.

Teachenor v. Tibballs, (Utah), 86 Pac., 483.

The place furnished by the master for his employees must not only be safe from such dangers as are latent, but also from such as are patent, and not alone from those in the place, but from such extraneous matters as menace the safety of the place, and which are ascertainable on reasonable inquiry.

Williams v. Sleepy Hollow Min. Co., (Colo.), 86 Pac., 337.

Where the owner of a mine knew of the existence of water in a neighboring mine in such quantity as to become dangerous to his employees, he was held bound to make such investigations as would suggest themselves to one using ordinary care and prudence, and if upon investigation he learned that there was danger of the mine becoming flooded, it was then his duty to make such provisions for the safety of his employees as would occur to a person of ordinary prudence, or to inform the employees of the danger. The standard of duty in such cases cannot be fixed by a court.

Williams v. Sleepy Hollow Min. Co., (Colo.), 86 Pac., 337.

An employer is always required to furnish a safe place for his employees to work. But a higher degree of care is required in this respect of an employer whose employees are underground with scant means of escape, than in cases where they are in a position to escape readily.

Williams v. Sleepy Hollow Min. Co., (Colo.), 86 Pac., 337.

While a miner assumes the ordinary risk of the manner in which guard rails are constructed, it was held that he did not assume the risk of the negligence of another miner raising the guard rails before the cage reached the level on which he and other miners were standing, where it did not appear that he knew that any one was in the habit of raising the rails until the cage was in place.

In an action for the death of a miner caused by falling down a shaft, it was held proper to prove that the rails guarding the entrance to the shaft were constructed and arranged differently from those intended for a similar purpose in other mines in the vicinity.

Vindicator, etc., Min. Co. v. Firstbrook, (Colo.), 86 Pac., 313.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. No assays are made.

Rock from Sheridan, Mont., marked D. G. D., is Chlorite and Magnetite, mixed.

Rocks from Korea, marked A. E. D., are: No. 1, Graphitic talcschist. No. 2, 4, and 5, Greenstone; No. 3, Gabbro.

White powders from Lower California, marked W. L. T., are mainly Lime Carbonate mixed with much sodium chloride and some sulphate.

Rock from Eureka, Nev., marked J. P., is so highly altered that the original character is obscured. It may have been a Rhyolite or feldspar porphyry.

Rock from Glen Ellen, Cal., marked J. H., is white Clay, presumably a decomposed volcanic tuff. It might be used with lime for cement manufacture.

Rocks from Fitting, Nev., marked W. E. C., are: No. 1, 2, and 3, locally metamorphosed rocks, allied to Hornfels and hornfelschist. No. 4 is Granite.

RADIUM.—Like any other physical theory, this one of atomic disintegration may, as observations accumulate, prove unequal to the description of new experiments; but, as matters stand, no competing explanation of the phenomena involved seems to cover and unify so wide a range of observed facts, and it will certainly not be abandoned until some other hypothesis is developed which will afford an equally intelligible and adequate model of the internal structure of the atom. The whole question is in its infancy, and much light may be expected during the next few years. Though, at the present time, the matter is of no immediate practical importance, the material interests of the race are involved in no remote degree. Our present civilization is based upon the possession of coal, and the output of mechanical power is increasing rapidly from year to year. In the not very distant future the supply of this indispensable commodity will be exhausted, and unless the human race can find some other source of energy, a relapse into barbarism seems inevitable. Recent experiments at Cambridge go to show that it may not prove wholly impossible to unlock the enormous reserves of internal energy which, on the hypothesis now under debate, are assumed to be locked up in the atom, though, in the experiments in question, this release of energy is only effected to a degree but little removed from the infinitesimal.—*Engineering*.

A RETURN-AIR PUMPING SYSTEM with a capacity of 1,000 gal. per min. has been installed by the Chattanooga Coal & Iron Co., of Chattanooga, Tenn., for obtaining its water supply from the Tennessee river. The operation of the return-air system of pumping was explained in the course of an article on 'Recent Extensions of the Employment of Compressed Air,' by Mr. Frank Richards in our issue of July 26, 1906. The pumping-plant consists of two Ingersoll-Rand Class R C air-compressors, having 16-in. stroke and 12 and 16-in. steam and air cylinders, respectively. The return-air system discharges into a series of settling tanks and thence into a cistern. The water is pumped from this cistern into a stand-pipe by a direct-acting steam-pump. These settling-tanks are necessary because the water of the river is extremely muddy. *Engineering News.*

A New Inland Sea.

The Colorado river continues to pour through the great cravasse in its bank in Mexico, ten miles below Yuma, Arizona, and is slowly filling the Salton basin, forming an inland sea. The flooding of this basin was the direct result of attempting to divert a portion of the water of

croached upon the upper end of the Gulf, eventually cutting the Salton basin off from its connection with the larger body of water, and in time, the great lake thus formed, became dry by evaporation. It is known that in seasons of high water, the Colorado river overflowed into the basin, probably frequently in the early history of the lake, but in time, as the river became higher, running in

the river from its natural course for the purpose of irrigating the arid land of Imperial valley. It is believed that at one time the Salton basin may have been directly connected with the Gulf of Mexico, which, at that time extended much farther northward than now. The Colorado river then emptied into the Gulf at a point far north of its present mouth, which is about latitude 31° 45' north, longitude 114° 45' west of Greenwich. Like all rivers carrying a large quantity of sediment, it built a constantly advancing delta at its mouth. The sand en-

a series of channels on the top of a broad plain of sand which sloped gently away from the stream for many miles, it gradually widened the barrier of detritus—at first a narrow and often interrupted sandspit—until it reached many miles into the basin, which was below the level of the sea, the successive overflows carrying the sand into the basin. These breaches in the natural levee were usually quickly filled by newly deposited sand, and the evaporation of the isolated body of water soon exceeding the inflow from the river and from other sources, the

lake began to diminish in size, eventually becoming dry. As it dried, it deposited on the lowest part of its floor the mineral salts from saturated solutions, which could no longer retain them in suspension.

This, briefly, was the condition of the basin and the river when the attempt was first made to artificially divert the river from its course for the purpose of irrigating the farms of the Imperial plains. The first canal was too small, and the large volume of sediment carried into it by the water, caused the canal to quickly shallow, and become useless. The canal was opened at points

calculated to give a better flow and steeper grade and head-gates were put in, but as before, the silt and sand settled about the gates and in the big ditch, rendering it useless. It was then determined to dig a larger and deeper canal, but this work was accomplished during a period of low water, without apparently having considered or, at least, appreciated the possibility of a high river and its consequent results. For a time the canal was considered a success, for the heavy grade permitted a continuous flow of water to pass along its entire length to Imperial. The new portion was 3,300 ft. long, 50 ft. wide and 8 ft. deep. When the first spring rise of the river occurred, a tremendous current rushed through the artificial breach in the natural levee, rapidly cutting the channel deeper and wider. On June 1, 1905, the river was discharging a total of 61,500 ft. per sec., of which 5,360 sec. ft., or 11%, entered the canal. On June 30, with the same river volume, 13,960 sec. ft., or 22% of the total flow, went through the canal. On July 30, the canal was taking 86% of the river flow, or 15,020 out of 17,500 sec. ft. On October 25, 1905, the full river discharge, which was then 6,000 sec. ft. was going through the canal. Numerous attempts, all thus far futile, have since been made to control this stream, but the physical

conditions are such as to render difficult all efforts, so long as rock foundation for restraining works is inobtainable.

With the hope of diverting some of the flow back to the gulf, a short channel was dug from the Alamo canal or river to the Padrones river not far from the Colorado and nine miles down the Alamo canal. This cut was designed to turn water into Volcano lake. A dam was built, or proposed, across the New river outlet of the lake, so the lake would discharge to the south and east, into the gulf, through an old channel called Hardy's Colorado, instead of to the northwest, through New river, into Salton sea. The result was different from that anticipated. The Padrones cut for itself a new channel north of Volcano lake, into New river, and the water found its lowest level in the Salton sink. The accompanying sketches illustrate the relative positions of the several canals connecting with the river. The relief map exhibits the topography of the entire region.

This problem has been previously referred to, and at

one time a rough calculation was made on the probable length of time that would be necessary for the river to fill the basin to a level with the river. This was estimated at 15 years, taking into consideration the evaporation. The following figures are from a report made by W. C. Hall of the United States Geological Survey. Mr. Hall surveyed the Salton basin and constructed a topographic map of it with 50 ft. contours, and with that information as a basis, he calculated the times that will probably be required to fill the basin to the various levels indicated in the table. These estimates are based on the flow of the Colorado river at Yuma, which has been determined by the observations of the past 11 years to be 8,000,000 acre-feet per annum, with an annual evaporation of seven feet. It is probable, however, that the factor of evaporation is too small.

The more recent efforts of the Southern Pacific Railroad Co., and of the company owning land in the Salton basin, to direct the river from the basin to its natural channel are said to promise greater success than heretofore, provided the river does not rise before these measures can be completed. In the event of a high river, the improvements thus far made are likely to be destroyed and the situation rendered worse than before.

The Copper Mines of the United States.

By WALTER HARVEY WEED.

*Copper mining in the United States has had a marvelously rapid development in the last ten years, showing an increase of 150 % in that time. The production for 1905 broke all previous records and brought higher prices than at any time for ten years past. The greatest increase in production was in Arizona, and the greatest individual increase, that of the Copper Queen mine at Bisbee, Ariz. The following table shows the production and relative rank of the different producing States, the figures for 1904 being those prepared and published by the Geological Survey, while those for 1905 are compiled from estimates by various trustworthy authorities.

PRODUCTION OF COPPER IN THE UNITED STATES.		
State or Territory.	1904. lb.	1905. lb.
Montana.....	298,314,804	319,179,885
Arizona.....	191,602,958	222,866,024
Michigan.....	208,309,130	218,909,753
Utah.....	47,062,889	51,850,789

North Carolina.....		700,000
Georgia.....		10,000
Total.....	814,035,719	879,015,652

The copper mines of the United States yield gold and silver as by-products and many gold mines yield small amounts of copper. The total gold produced by the copper mines of the United States in 1904 was 237,116 oz., distributed as shown in the table below:

PRECIOUS METALS CONTAINED IN THE COPPER ORES OF EACH STATE.		
	Gold. oz.	Silver. oz.
Utah.....	109,968	2,572,582
Arizona.....	47,563	1,464,731
Montana (Butte).....	44,400	10,236,119
California (Shasta).....	24,727	844,265
New Mexico.....	4,137	79,369
Colorado.....	3,288	131,695
Appalachian States (estimated).....	1,066	79,600

Oregon.....	326	11,677
South Dakota.....	145	789
Nevada.....	10	2,519
Michigan.....		122,807
Total.....	237,116	15,768,307

The distribution of the copper mines of the country is shown on the accompanying map.

The Butte copper district is the greatest silver-producing camp of the entire world, its production being 10,236,119 oz. in 1904. Utah leads in the amount of gold produced from its copper ores, Bingham and Tintic yielding 109,968 oz., the ores also carrying 2,572,582 oz. silver. The Arizona mines yield more gold than the Butte mines, but far less silver.

The marked change from lead to copper as a collector of precious metals in smelting practice is one of the notable features of recent years, and has furnished a market for gold and silver ores whose copper content was not formerly paid for, 3 % copper being long considered the minimum.

The most striking feature of copper mining in the last two years is the complete success of experiments made in the treatment of the so-called disseminated ores, in which small particles of copper sulphides occur disseminated through altered porphyry. Enormous bodies of this class

of ore occur at Morenci, Ariz., at Bingham, Utah, and at Ely, Nev., which were formerly considered of too low grade to work, but which have been proved to yield a handsome profit when treated in concentrating mills and concentrated 10 to 20 into 1.

The extent to which these great bodies of 'disseminated' ore will contribute to the world's supply of copper can be estimated from the fact that preparations are being made to mine and mill 12,000 tons of this ore per day at Bingham and nearly as much at Ely, while the mills of both the companies at Morenci have been greatly enlarged. Although similar disseminations of glance and pyrite in altered granite alongside of and between the veins at Butte have long been milled, it has been customary to regard a 3 % or even a 4 % ore as the lowest grade that could be profitably treated, whereas at the localities mentioned above the grade is much lower, as shown by the following table, after J. P. Channing :

TENOR OF DISSEMINATED COPPER ORES.		Per cent.
Morenci, Ariz., Arizona Copper Co.....		2.6
Morenci, Ariz., Detroit Copper Co.....		3.0
Bingham, Utah, Utah Copper Co.....		1.9
Bingham, Utah, Boston Con. Copper Co.....		1.4
Ely, Nev., Nevada Con. Copper Co., Ruth mine.....		2.6
Ely, Nev., Nevada Con. Copper Co., Eureka mine.....		2.2

It is evident that the price of the metal will determine the minimum grade of copper ore that can be treated at a profit. The above ores can be made to pay with copper at 12 cents per pound.

The widespread adoption of pyritic or raw-sulphide smelting, in which the fuel value of the sulphur is utilized, has had its effect on copper mining, as, indeed, have the introduction of labor-saving devices at the smelters and the improved mechanical arrangements which have lowered the cost of treatment and so led to the mining of lower-grade ores. The cheapened smelting costs have given a long lease of life to various old properties by enabling bodies of lean and previously unworkable ores to be reckoned as ore reserves, while pyritic smelting has led to a demand for pyritic ores as a fuel flux to be added to silicious ores. If it be true, as an eminent metallurgist has epigrammatically expressed it, that "roasting is a crime and concentration a felony," the ores now concentrated will some day be treated direct in the blast-furnace, mixed with pyritic ores, as is now being done at the Pittsmont smelter at Butte.

It has not been found practicable, nor is it especially desirable, to separate the production of milling and of smelting ores. At Butte, the smelting ores form from 6 to 10 % of the total amount mined, the proportion varying at the different mines. The entire production of the Utah and of the Boston companies at Bingham, Utah, will be milling ores, and at everyone of the Arizona camps the proportion of milling ores used is increasing each year. The California ores, like those of Ducktown, Tenn., are basic sulphide ores, an ideal material for pyritic smelting.

Copper ores can be grouped commercially into smelting, concentrating, and leaching ores. All three kinds often occur at the same mine, but the distinction holds good in a general way. Smelting ores may be either pyritic, with an excess of iron, or silicious, carrying an excess of silica, though the lower-grade silicious material is often classed as concentrating ores. Pyritic ores are found at Ducktown, Tenn., and in Shasta county, Cal., while the smelting ores of Butte are well-known examples of silicious ores which need basic flux added to them to insure successful treatment.

In some cases, owing to the physical character of the ore and the minute intergrowth of ore and gangue minerals, concentration is not feasible. In such cases direct smelting with the production of a low-grade matte is possible, provided basic ores can be obtained. In any

*Abstracted from 'Contributors to Economic Geology,' 1905, United States Geological Survey.

case the loss in wet concentration is considerable, varying from 20 to 35 per cent.

In recent years self-fluxing ores have been found at a few localities—as, for example, at the Boundary Creek region in Canada and in the mines of the Saddle Mountain Co. on Gila river, Arizona—and in such cases ores particularly low in copper may be treated at a profit, provided coke can be obtained at a reasonable figure. The utilization of low-grade garnetiferous contact-metamorphic ores is still a problem for the metallurgist, and although various attempts have been made to treat such ores, particularly in the San Pedro mines in New Mexico, success has not been attained.

The Lake Superior ores may be considered ideal for concentrating, for the native metal is tough and does not slime, as do the brittle sulphides when they are pulverized to liberate their metallic content.

From a geological standpoint the producing copper deposits of the United States may be grouped as follows:

(a) Deposits in altered limestones, showing contact-

duction of 221,000,000 lb. for 1905 is all from one type of deposit, while the lenticular deposits (*d* and *e*) yield 36,000,000 lb. The grouping given above is intended to express broad features and is not given as a satisfactory classification. Form is an important factor from the mining standpoint; mineral character of ore and of gangue from the smelter's point of view.

The first group, which for convenience may be called the Morenci type, should really include groups *a* and *b*. At each of the great mining centres—Morenci and Bisbee, Ariz.; Cananea, Mexico; Bingham, Utah, and Ely, Nev.—The distribution of the copper deposits is co-extensive with a great porphyry stock and its dike systems. Areas devoid of intrusions are barren. The lodes are essentially copper deposits, with very minor amounts of gold and silver. The workable deposits of these localities occur either in the limestones or in the porphyry. In limestone they are confined to areas showing marked contact metamorphism, and the sulphides replace the original rock material, are intergrown with the contact minerals,

Distribution of Copper Mines of the United States.

metamorphic characters, and adjacent to eruptive rocks (Morenci type) in part characterized by deposits of group *b*.

(b) Deposits in fissured and altered igneous rocks, in part as veins, in part as dissemination and impregnation of shattered or porous rocks of other kinds (Morenci).

(c) Replacement veins in sheeted granitic rock (Butte type).

(d). Lenticular masses of solid, nearly pure, pyritic ore in shear zones in igneous rocks (Shasta county type).

(e) Lenticular deposits (similar to *d* in shape and mineral character) in metamorphic schists (Ducktown, Tenn.; Ely, Vermont).

(f) Deposits of native copper in altered amygdaloidal basic lava and interbedded conglomerates (Lake Superior).

(g) Normal fissure veins and impregnations of similar genesis.

The class first named, the contact-metamorphic deposits, yield about one-fifth of the total copper produced in this country. The allied disseminated ores yield about 50,000,000 lb., excluding Butte's production. The Michigan pro-

duction of 221,000,000 lb. for 1905 is all from one type of deposit, while the lenticular deposits (*d* and *e*) yield 36,000,000 lb. The grouping given above is intended to express broad features and is not given as a satisfactory classification. Form is an important factor from the mining standpoint; mineral character of ore and of gangue from the smelter's point of view.

The disseminated ores and associated fissure-vein deposits carry pyrite, with or without chalcopyrite and often with zinc-blende and molybdenite, with but little quartz gangue, in altered porphyry. The ores are low grade and in many cases workable only as far down as secondary re-concentration (enrichment) has occurred. The porphyry is altered, usually greatly so, by late hydrothermal action, in the latter case consisting of sericite, quartz, and pyrite. Where the fissures pass into other rocks alteration and ore deposition also occur, except in those already altered by contact action.

WITHIN a finite time past the earth must have been, and within a finite period of time to come the earth must again be, unfit for the habitation of man as at present constituted, unless operations have been, or are to be, performed which are impossible under the laws to which the known operations going on at present in the material world are subject.

Rope Haulage at Broken Hill.

In the Annual Report of the Department of Mines, New South Wales, there is a description of endless rope haulage, used in conveying ore from the Delprat shaft of the Broken Hill Proprietary mine to the mill. It is stated:

Delprat shaft, through which the total output of the mine is pulled, is distant from the ore-bins about 360 ft. The height of the brace above the rail over the bins is about 10 ft. Previous to the installation of endless-rope haulage, the ore was run in the mine trucks from the brace of the shaft to the ore-bins by a gravity or self-acting incline, running in trains of eight.

With a view to economy of labor, the system under description was adopted. This consists of a $\frac{5}{8}$ -in. wire rope of proper length with the ends spliced together, running continuously round two grooved pulleys eight feet in diameter, revolving horizontally. These pulleys are placed one at the shaft end and another at the mill end of the track. One is used as the driving pulley, and is actuated by an 8-h. p. steam-engine; the other is built on a carriage traveling on rails, and from the end of which suspended weights maintain a continual and regular strain on the rope, and thus automatically adjust the stretching of the rope from any cause whatever. The shaft and ore-bins are so situated that an angle of about 110° has to be negotiated. This is done with a 60-ft. radius curve, the rope being kept nearly central to the track by means of flanged vertical pulleys spaced about 8

to 10 ft. apart. On the straight, horizontal rollers 6 in. diam. and 8 in. long prevent the rope from rubbing along the ties.

The clip for attaching the truck to the rope is of simple construction, and consists of two tapered jaws of steel over which is dropped a collar or thimble, and attached to truck draw-bars by means of a ring passing through the upper end of both jaws. The rope catches in a groove or grooves, as shown on accompanying sketch.

After a truck passes over the weighbridge, which is close to the shaft, it runs by gravity on a level stretch of track about 15 ft. in length; there the hooker-on places a clip on the hook of the truck, lifts the thimble and places the jaws of the clip, one on each side of the rope, then drops the thimble. The clips immediately seize the rope, and the truck is pulled over the brow of the incline, where the strain is reversed and the truck pulls on the rope. This continues until the tangent point of the curve is reached, when the friction of the curve gradually overcomes the force of gravity, and from thence the truck is hauled by the rope. About 30 ft. from the first or No. 1 tippler, the trucks are detached from the rope automatically, and as this is at the crest of a rise the trucks—freed from the rope—gain a little speed and run into whichever tippler the points are set for.

There are four tipplers, one over each bin; these are circular frames on four rollers into which the trucks run, and at such a height that the centre of gravity of the full loaded truck is above the centre of the tippler, so that when the chairs, of which there is a set to each tippler, are withdrawn, frame and truck automatically complete one revolution, the contents of the truck being discharged

as it attains the inverted position. Angle-irons, riveted to the tippler at such a height as to allow the wheels just to pass under, catch, and thus prevent the truck from falling out of the tippler. To prevent the tippler coming back on to the chairs with too great a jar, a rim-brake is attached, worked by foot.

The truck having been emptied, the next on-coming full truck bumps the empty one out of the tippler, which runs by gravity on to the empty line, where it is attached to the rope in the same manner as the full ones already described. It is now hauled by rope to the top of the incline, where it is automatically detached, and from this point runs by gravity to the back of the shaft, where the clip is taken off and placed on a conveyor actuated by the haulage rope, and by that means deposited at the point where the full trucks are hooked on ready for another trip.

The arrangement for detaching is simply a short inclined plain, with a slot running centrally along it wide enough to allow the jaws of the clip to pass through, but necessitating the thimble riding on top. The rope at this point is kept down by a depression pulley, so that when the clip enters the knock-off, the downward strain of the rope pulls the jaws down; but as the thimble cannot come down but is being gradually lifted higher on the incline, the result is that the thimble flies off and the rope is released.

The speed of the rope is about 110 ft. per min. or a mile and a quarter per hour; 200 trucks per hour are handled easily. The wear and tear on trucks is reduced to a minimum, the speed being so slow that severe bumping or spragging is unknown. The engine driving the rope is used more as a controller than a motive power, for the full trucks going down the incline pull the rope and empty trucks round. The labor saved is considerable.

A CASE of cheap hydraulic power was mentioned by Prof. K. Birkeland, of the University of Christiania, Norway, in a paper recently read before the Faraday Society at London. In describing the plant for producing nitric acid and nitrates from atmospheric nitrogen by means of his disk-shaped electric arc flame, he stated that the electric power (5,000-volt alternating current) costs the company only 25s. (\$6.08) per electric horse-power-year. The cost of producing this power, he stated, is only 11s. (\$2.67) per electric horse-power-year. The output of the furnaces using his process is said to be a minimum 500 kg. anhydrous nitric acid per kilowatt-year. Then at the price of 25s. per e.h.p.-yr., or 33.3s. per k.w.-yr., the power-cost per ton (1,000 kg.) of acid appears to be 67s., or with a yield of 600 kg. per k.w.-yr., it would be 55.5s. per ton. Prof. Birkeland quotes a total cost of £4 per ton of acid, so that the power-cost makes up well over half of the cost of production. The remarkably cheap power available for the process (at Notodden, Norway) is evidently the prime factor in making the process commercially applicable.

PLATINUM.—The price of platinum has been going up rapidly of late, largely as a result of disturbances in Russia, from which country practically all of the supply of that metal comes. It is now 50% higher in price than it was a year ago, selling at \$28 per ounce. A year ago it sold for \$18 and \$18.50. The present price is three times that of 15 years ago. According to reports circulated among refiners, the Russian Minister of Commerce is now considering measures either for placing a heavy export tax on the product, or for prohibiting altogether its exportation except after it has been refined in Russia. Nearly all of the metal now exported is in the ore.—*Iron Age*.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

ROASTING OR OXIDIZING FURNACE.—No. 828,095; Chauncey E. Dewey, Denver, Colorado.

In a furnace of the class described, the combination with a centrally-located revoluble shaft and rabble-arms adapted to enter sockets with which the shaft is provided, each socket being provided with a lug, located in its lower portion and each rabble-arm being flattened on one side and

also provided with a lug, the rabble-arms being also adapted to turn in the sockets of the shaft, the lugs of the rabble-arm and socket being so arranged that by giving the arm a partial turn it may be inserted to bring its lug inside of the plane of the socket lug, whereby when the arm is turned to bring its plows into the operating position, its lug will occupy a position inside and engaging the lug of the socket to prevent the removal of the arm by a direct outward movement, and to hold plows in an upright position.

ORE STAMP-MILL.—No. 828,126; Thomas E. Lambert, Butte, Montana.

A stamp-mill, comprising one or more vertical stems, having shoes at the lower ends thereof, dies co-operating with the shoes, tappets on the stems, a shaft, and cams

thereon for engaging with the tappets, coiled springs on the stems, upper and lower guides for the stems, and means for preventing contact of the coils of the springs with said

stems, embodying flanged collars upon the tappets, and similar flanged collars at the upper ends of the springs, the said collars extending within upper and lower coils of the springs.

APPARATUS FOR ELECTROSTATIC SEPARATION.—No. 827,116; Greenleaf W. Pickard, Amesbury, Massachusetts.

In an electrostatic separator, a source of electrical energy, electrodes, means to supply the material thereto, means to

heat the material before it reaches the electrode, and means to maintain a heated atmosphere about the electrode into contact with which the material is delivered.

APPARATUS FOR CYANIDING ORES.—No. 830,615; Thomas L. Rankin, Sackett Harbor, New York. Filed June 11, 1906. Serial No. 321,086.

In apparatus for cyaniding ores, a rotary leaching cylinder adapted to retain compressed air during the operation of leaching and means for supplying compressed air to said

cylinder, and means for rotating said cylinder in combination with a second cylinder for receiving the excess of compressed air and contained gas from said leaching-cylinder, and means for equalizing the pressure between said cylinders

Lode-Stone Picked Up by a Dredge.

Not long ago in cleaning up the wells and sluice-boxes on the Allis-Chalmers gold dredge, owned and operated by the Bonanza Basin Gold Dredging Co., in the Bonanza basin, Alaska, a perfect specimen of magnetic iron ore, or lode-stone, was found. Though worn to a rounded pebble one inch by one-half by three-quarters, the specimen retained so strong a polarity that the accompanying black sand was held attracted to it and picked up in great black ropes, thus first attracting attention to the curious substance.

Masses of iron ore in a state of magnetic polarity, constitute what are known as 'lode-stones,' or native magnets. They occur in extensive beds and are met with in granite, gneiss, mica, schist, clay-slate, syenite, hornblende, and chlorite-schist. The lode-stone was well known to the ancient Greeks. Pliny called it Magnes, from the name of the country Magnesia, a province of ancient Lydia, where it was found. Its discovery gave to science the terms 'magnet' and 'magnetism.' The first compasses were magnetized by contact with lode-stones. By a mere touch to a steel object, strong magnetism is imparted seemingly with-

Commercial Paragraphs.

THE A. LIETZ Co., manufacturers of surveying and nautical instruments, have returned to their old location at 632-4 Commercial St., San Francisco.

COLORADO IRON WORKS Co., of Denver, has received an order from the Tonopah-Liberty Mining Co. for a 10-stamp mill, with concentrating equipment, to be erected this fall near Tonopah, Nevada.

THE PACIFIC HIGH EXPLOSIVE Co. has a temporary office at 100 Bacon Bdg., Oakland, Cal., and the management states that it will be ready in a short time to place this product on the Western market.

INGERSOLL-RAND Co., of New York, have issued catalogue No. 45 B, giving a detailed description of their Ingersoll-Sergeant rock-drills, with tabulated specifications and capacities of each type and size, with comments on the work for which each is adapted. A list of 44 questions covering the problems of rock-drilling under all conditions is given. The book closes with several pages devoted to tables of useful information on compressed air.

P. C. McCABE & Co., of Los Angeles, publish an attrac-

Double-Lift, Long Sluice, Gold Dredge.

out any loss of energy in the stone itself. The existence of this curious mineral, doubted by many philosophers of old, gave rise to many a story of romance and adventure. In ancient times, kings were proud to own small specimens such as that found in the sluice-boxes and taken from the Klondike river. There is today no monetary value attached to magnetic iron ore. Steel is readily magnetized by currents of electricity for use in navigation and for scientific instruments.

The history of the process of gold dredging, by means of which the specimen above described was recovered, is interesting, as showing the trend of modern development. Though based primarily upon the recovery of a very small amount of precious metal in a comparatively large bulk of inert material, the industry has shown itself capable of being conducted at considerable profit. The comparative simplicity of the dredging operation is the main reason for this, coupled with the elimination of all labor problems; for only a few men are required to operate the machinery. Within recent years the mechanical part of the construction of dredges has been largely advanced, due regard being paid to the nature of the work which the dredge is intended to perform, with a view to making the mechanism as strong and simple as possible and adapted to the somewhat rough and difficult conditions under which many dredges have to operate. The Allis-Chalmers Co. make it their business to design and build dredges adapted for special work.

tive pamphlet describing their New Standard Concentrator. It is handsomely illustrated and gives details of this useful machine, together with an appendix containing data on the specific gravity of minerals and other information serviceable to the millman. A number of copies of testimonials, from mill managers testify to the excellent work accomplished by this concentrator.

AN interesting little concentrating plant, with the heavy pieces of machinery sectionalized for mule-back transportation, was shipped recently to the Venture Corporation, at Guatemala City, by the TRAYLOR ENGINEERING Co., of New York. The plant was designed in New York and shipped with all parts complete and ready to set up. The building to enclose the plant was designed so that it could be built throughout of logs or poles. The outfit consists of a 4 by 6 ft. grizzly, a 7 by 10 in. Blake crusher, ore-gate irons, two 32-ft. bucket-elevators, two sets of 22 by 10 in. crushing rolls, one 10-in. plunger feeder for the rolls, one double unit centripact screen, one single unit centripact screen, one 24-in. sizer, one 30-in. sizer, one two-compartment Hartz jig, one one-compartment Hartz jig, one unwatering screen, two concentrating tables, one 9 by 12 in. automatic steam-engine, one 8 by 10 in. automatic steam-engine, and 24-h. p. water-tube boilers; iron-work for settling tanks, belts, shafting, and all other details necessary to make up the complete plant, and complete erecting plans were included in the shipment.

Editorial.

INSERTED LOOSELY in this issue will be found the index for Vol. XCII, covering the issues of the first six months of the current year.

THE COMPLETION of the railroad to the Bullfrog district, in southwestern Nevada, is an event of importance. The rails are now laid from Beatty to Las Vegas, on the Salt Lake & Los Angeles line, and it is certain that no time will be lost in extending this branch—the Las Vegas & Tonopah Railroad—to Goldfield. Already many car-loads of machinery have been delivered by the new railroad. We congratulate the Bullfrogs on the Amargosa.

THE CONTRIBUTOR who gives us a leaf from his biography in 'The Experiences of a Tenderfoot' will awaken many memories among men now gray in professional service. We laugh with him at the simplicity of the tenderfoot—the tenderfoot that each of us was once. Every mining engineer will remember vividly his first appearance on the field of action, his preconceived notions of a mining community, his ingenuous ideas of its requirements, his first days of honorable labor. Others are going through the same experiences today, only they will not know it until twenty years hence.

MINING COMPANIES are not often generous in recognizing the value of an engineer's devotion to their interests; therefore the action of El Oro Mining & Railway Company, at the recent annual meeting at London, in voting a handsome bonus to Mr. Robert M. Raymond, the manager, and Mr. Alfred F. Main, the assistant manager, at El Oro mine, in Mexico, is an incident that it is pleasant to chronicle. We happen to have some acquaintance with the operations of the company, having visited the mines and mills at El Oro, therefore it is a pleasure to record such appreciation of good work. If the relations between the local management and the directorate at London are, in this case, unusually cordial, it is due to the fact that the latter includes several men of wide experience in mining. The sympathetic intelligence of directors that have been through the mill of experience is worth a great deal to a mine manager; in fact, it is the best help he can have—next to plenty of pay-ore.

A CORRESPONDENT writing from New York makes a protest against the common practice of erecting mills and metallurgical works without proper advice. He makes his point so well that there is no need for us to emphasize it. Naturally, the people that sell machinery are willing to give gratuitous advice as to the sort of plant the purchaser should select, because it enables them to dispose of the products of their own manufacture, just as a real-estate agent will, if consulted, recommend property

which is on his books. We do not blame them; often their suggestions are good, and it is certain that the best firms cannot afford to take unfair advantage of the simplicity of customers. But it is high time for the public to learn that to buy mines without the advice of men experienced in such matters or to erect a mill without consulting those who have made a life-study of metallurgy, is an ancient blunder, for which they will pay with undeviating certainty. So long as people make important contracts without consulting a lawyer and dose themselves with drugs without seeing a doctor, so long will they also do the other foolish things that undermine the prosperity of the mining business.

A Passing Era.

The removal of the ruins of the old Stock and Bond Exchange on Pine street takes away the last link with a bygone era — that of the bonanza days on the Comstock. Of the old building only a part of the front wall survived the earthquake-fire, and with the demolition of that remnant the survivors of the great days in Nevada have lost a landmark in San Francisco. It will require sixty days to take away the debris, and then the old rooms where Con. Virginia sold for \$750 per share, California for \$850, and Crown Point for \$2,000 will be no more. The sentiment of the older generation deserves respect, but the fraud and the folly of the Comstock boom deserve none. Despite the tremendous yield from the big lode on Mt. Davidson, the Comstock did more harm to mining than it did good; it made the fortunes of a few and worked the ruin of many. Another era has been ushered in; as the ruins of the former exchange are carried away to fill a marsh or make a grade, the air is full of good news from the young camps in Nevada, in a region considered almost impenetrable thirty years ago. As the old giant on Mt. Davidson shrinks with age into a dishonored grave, let the youngsters take heed to avoid the chicanery and insane gambling that made the Comstock a curse. Farewell to the past; greeting to the present. May the records of Tonopah, Goldfield, and the whole galaxy of mineral districts on the western border of Nevada make history as Virginia City did, but let them not duplicate her dishonesty, nor be sullied by her shame.

Taxation of Timber.

It appears that, by a reciprocal arrangement of the tariff in New Zealand and Australia, the import duty on mining timber is to be trebled, the idea being to encourage the use of the native product in place of oregon pine. New Zealand is responsible for this latest development of tariff eccentricity, although it seems unlikely that the kauri can be used in mining. Australia produces excellent timber for special purposes, such as railroad ties and block pavements, but the native woods are too heavy, brittle, and short-grained for employment underground. At Broken Hill, the additional expense to be incurred by reason of this tax on oregon pine will amount to a large sum, and at other centres in Australia the cost of timbering will be needlessly increased; and to little purpose, for it is unlikely that the intention of the impost — to

encourage the use of the native woods — will be achieved. In the meanwhile the great demand for lumber in rebuilding San Francisco will cause us to smile at this Australian taxation. There is use for all the oregon pine that is obtainable. The price of lumber has risen from \$13 to \$30 per thousand feet, and the inadequacy of the supply even at these artificial prices established by greedy companies, eager to make money at the expense of a stricken community, is apparent throughout the cities of the Pacific Coast. There is plenty of use for American timber and lumber much nearer home than Australia. It is better used in the homes of our people than consumed in supporting holes in the ground on the other side of the equator.

The Mining Congress.

Another annual session of the American Mining Congress has been held and it must be allowed that it was a useful gathering, likely to further the best interests of the industry to which it is dedicated. The Congress has not made much headway during recent years; it is true that it was rescued from disgrace and it has been properly organized, but the support expected from the mining community has not been accorded in anything like full measure. Nevertheless, the earnest efforts of a few public-spirited men are beginning to have their effect and it would give us much pleasure to see the Congress develop into a useful institution. At all events, we recognize the singleness of purpose shown throughout the last three years by the president, Mr. J. H. Richards, and we appreciate the hard work done by some of his immediate supporters. At Denver last week the local people did not evince much interest in the opening proceedings, but to the later discussions they came in goodly numbers, and when the Congress took in hand such subjects as fraud in mining, drainage districts, and smelter settlements, the attendance was creditable, in quality as well as quantity. When thoughtful men like D. W. Brunton, Franklin Guiterman, W. R. Ingalls, R. L. Herrick, and our own governor, Mr. George C. Pardee, take a hand, it is obvious that something useful is likely to be evolved. Of course there were some queer people who made themselves prominent and there were others who made aimless speeches, but the gathering would not have been representative without them, and communities need safety-valves. That beneficial work was done there is no gainsaying, and that the Congress made a distinct step forward was obvious to the fair-minded. We wish it further success, whether it be under the leadership of the good citizen from Idaho, or whether he passes the gavel to Mr. Thomas F. Walsh or Mr. John Dern, both of whom are mentioned for the presidency. We need an occasion to foregather, a sort of rallying ground for men of ideas, a coming together of those with a purpose, and a talking mill for concentrating public opinion. Some such parliament of mining men is destined to play an important part in the ethics, the legislative control, and the financial methods applied to the great industry to which we are devoted. We look to the Mining Congress to fulfill that ideal.

By the Way.

At the recent session of the American Mining Congress, a paper was presented by Dr. R. W. Raymond on the history of the American Institute of Mining Engineers. He said:

The period following the war for the Union was characterized by great activity in mining, and a great demand for mining engineers. The mining industry of the Pacific States had been, ever since the discovery of gold in California, the leading factor in the settlement of the country, the improvement of communications and the establishment of civilized communities, with auxiliary agencies of commerce and manufactures, as well as education and religion. The governmental aid given to the Pacific railways, on the ground that these lines were military necessities for the handling of the Indian tribes and the maintenance of sovereign Federal authority throughout the vast Pacific slope, could scarcely have been secured, had not the mineral resources of that region given it a thrilling romantic interest and a boundless value in the eyes of the people of the East. At the same time, the exploitation of the western mines and the rapid development of coal, iron, copper, and lead mining in the older States, called for trained engineers; and successive technical schools were established in response to this demand, while technical journals flourished, and became more and more devoted to problems of theory and practice, as well as records of new enterprises. Meanwhile, the actual mining engineers of the United States—those who were doing the great work of mining both East and West—could not be said to form an organized profession at all. There were a few graduates of foreign schools, many civil engineers who had turned their attention to mining; a much larger number of miners from Cornwall or Germany who had risen to be mine-captains and experts; and a still larger number of self-taught American miners and prospectors, ignorant and jealous of book-knowledge, and over-conscious of superiority in many respects to its possessors and professors. This heterogeneous multitude had no common ground for the interchange of views and experiences, and no organized common feeling inducing them to seek and occupy such a ground. The technical journals and the technical schools alike needed to be reinforced in their endeavors by some agency which should promote personal acquaintance and mutual esteem among the men in whose hands were the mining operations of America.

It was my realization of this feature of the situation that led me, as the editor of *The Engineering & Mining Journal*, to attend at Wilkes-Barre, in May, 1871, the meeting called by three mining engineers, Eckley B. Coxe, Richard P. Rothwell, and Martin Coryell, to organize an association. As a beginning, in default of a duly elaborated scheme to suit our special case, the rules of the North of England Institute of Mining Engineers were adopted in substance, and the name of 'The American Institute of Mining Engineers' was chosen for the new society without debate, as a matter of course. The rules were subsequently re-written; but the name, though in some respects a misnomer, since it does not fully describe the scope of the Institute, has survived, and has become so dear to the members and so well-known to the world that it is not likely to be changed.

At the outset, a most important question arose, the settlement of which involved the whole future of the society. Several educated engineers protested against the admission to full membership of persons not belonging to the profession, and not possessed of a certain degree of professional standing and experience. They could not insist upon the degree of M. E. or E. M. as a qualification. They did not themselves hold that degree;

but they felt that C. E., or its equivalent in certified experience and knowledge, ought to be required. In a word, they did not wish to recognize as fellow-members (though they would consent to admit as associates), common miners, foremen, and self-educated mine captains.

There was much to be said in favor of this feeling. Professional societies usually represent professions, and membership in them is accepted as a guaranty of professional standing. Consequently, they make careful preliminary examination into the training and achievements of candidates, and sometimes impose a period of quasi-probation as 'junior' before advancement to full membership. All this is excellent, for the purpose for which it was designed. But that was not the purpose of the Wilkes-Barre meeting of 1871; and if that had been its purpose, the movement would have failed. This point is so important as to warrant further explanation.

There was at that time no such thing in the country as a distinct profession of mine-engineering, numerous enough to support an active and useful society. Any attempt to create one by means of a society would have resulted in a small, select (i.e. self-selected) coterie, barren of influence and outside of practical connection with the national mining industry.

The pressing need of the hour was not the segregation of a select body, but the cordial co-operation of all the representatives of a great industry or group of industries. This could only be effected by bringing together on terms of friendly equality the school-men and the field-men, and persuading the latter to do what they were naturally shy and reluctant in attempting, namely, to tell what they knew, for the benefit of all. Unquestionably the self-educated practical mining men and furnace-men at that time knew more than the school-graduates about the actual facts of American ore deposits, mine-workings, and furnace management. It was not the nominal manager but the Cornish captain who knew the mine; it was not the chemist but the founder who ran the furnace. If these practical men were slighted at the beginning, they would stand aloof, giving no aid in the way of fresh facts, and leaving the theorists to exchange their speculations with little profit, like the traditional boys confined in the garret, who professed to have made money by swapping jack-knives, back and forth.

Again, the work of publishing and distributing useful information could only be done upon an influential scale by a society with a large income; and this would require either a select, small society supported by heavy annual dues, or a numerous membership paying small dues. Beyond question, the latter was both easier to secure and more fruitful of influence as well as revenue. The result of thirty-five years' experience has left no doubt on that head. What the Institute has given to its members in the way of publications for the annual fee of \$10 may be confidently compared in both quantity and quality with the similar publications of any society in the world, supported by annual dues of twice or thrice that sum.

Another point is worthy of note. A large membership, even if it be not narrowly confined to men of a certain ascertained standing in a single profession, furnishes an attractive and inspiring public to ambitious authors. A famous engineer (member of several other American and foreign professional societies, as well as of our Institute), once said to me: "The Institute is an association largely composed of young men with reputations to win, instead of older men with reputations to maintain. The consequence is, that your members are eager to communicate what they know or think, instead of being afraid to 'give it away,' or reluctant to incur criticism by offering professional contributions not monumentally complete and creditable to their acknowledged professional standing."

Special Correspondence.

Melbourne, Australia.

Ventilation of Deep Mines.—Interesting Investigation.—Shall Tuberculous Miners be Permitted Underground?—Zinc Processes at Broken Hill.—The Half-Yearly Report of the Broken Hill Proprietary.—A Splendid Showing From the Great Mine.

The mining event of the past fortnight has been the publication of a special report by Dr. Summons on the ventilation of the deep mines at Bendigo. One of the shafts in that district goes down to a depth of 4,200 ft. and several are more than 3,000 ft. deep. The steady increase in miner's phthisis at Bendigo has been occasioning alarm, not only among the miners themselves, but to the ordinary residents. Bendigo has one of the finest climates in the world for sufferers from chest complaints—a hot, dry summer with a bracing winter—so that under normal conditions deaths from phthisis should be rare. Local medical practitioners have traced the spread of the disease to the undermining of the system by fibrosis due to the inhalation of the dust in the mine workings; also to the defective ventilation. To carry the investigation further, the trustees of the Wilson estate, constituting the larger interest in the Melbourne *Argus*, who, by the will of the testator, have to devote the profits coming to them from that paper to charitable purposes in the State of Victoria, gave a sum of money to the committee of the Bendigo hospital to defray the cost of a prolonged inquiry by a competent medical man. The hospital committee selected Dr. Walter Summons, who has spent six months up and down the mines. His experience may be summarized in the statement that in some of the workings "there was only a sheet of paper between the miner and hell." He found that in mines whose bottom workings are connected, such as Lansell's 180 and the Victoria Quartz, at a depth of over 3,000 ft. where there are upcast and downcast currents, the temperature was about 80° F., indicating that with natural ventilation under the best conditions such a temperature must be expected at that depth, owing to the heat of the rocks. In hot raises and the dead ends of cross-cuts, the heat was greater, dust was always perceptible in great quantity, and there was an undue percentage of carbonic acid gas in the atmosphere. Dr. Summons cited the case of the Suffolk mine where, by the use of the spray, the manager reduced the temperature perceptibly, and brought both the dust and CO₂ down to a limit well below what may be termed the danger point. He therefore advocates the use of the spray, as well as the air-jet, the effect of which is apparent from 30 to 100 ft. ahead of the spray. Local legislation provides for the use of the spray, but the law has not been enforced. There is no doubt that this will now be done and it is equally certain that the whole question of ventilation will be dealt with during the present session of the State Legislature. Dr. Summons also recommends that the mines be connected, the smallness of the properties favoring that step; he suggests that centre-country winze and shaft be sunk simultaneously instead of the first-named preceding the latter, and that cross-cuts be made to the winze at every 100 ft. Stated in a sentence, the report is: 1. Rely on natural ventilation where practicable. 2. Improve the working conditions in the hot raises and dead ends by the aid of cross-cuts and drifts and by the use of the spray and air-jet. The mining community has endorsed these recommendations, but it halts at the medical corollary: Stop the tuberculous workman from working underground. Dr. Summons is emphatic on this, and I see that Dr. Irvine preaches practically the same thing for the Rand. The

miners say that such a drastic step will throw many families into a state of destitution, but that evil is less than the continuous infection of the mines by dangerous subjects. The Minister of Mines takes this view, for he says: "I consider the recommendation, that miners suffering from tuberculosis should not be allowed to work underground, a valuable one. If a person suffering from tuberculosis is a source of danger except under properly guarded conditions on the surface, the danger underground must be multiplied a hundred-fold." It may be added, as showing the heat in some of the deep workings, that in the Victoria Quartz cross-cut at 3,800 ft. last week, a stream of water having a heat of 113° F. was cut.

The Zinc Corporation, which was formed by Bewick, Moreing & Co. and Lionel Robinson to handle the big heaps of zinc-bearing residues at Broken Hill, has exercised one of its large options. This is the purchase of 520,000 tons of residue from the Block 10 mine, for which it has to pay 5s. per ton, equal to £130,000. Payments are to be spread over five years in quarterly installments of £6,500 each, and a deposit of £10,000 has been made to bind the bargain. The company is very reticent about

Eastern Australia.

how things have been going with it at Broken Hill, but outside local managers say that the company's experts are not finding the problem of dealing with the tailing as easy as expected; at all events, the company's plant on the British mine, where they were using the Potter sulphuric acid flotation process, has been shut down for some time. The trouble appears to be that the climate at Broken Hill favors rapid oxidation of the sulphides on the dump, and so the high recovery expected does not appear, as yet, to have been obtained. The Delprat process, which is a modification of the sulphuric acid process, salt cake being employed to give density to the solution, has been worked on a large scale by the Proprietary company during the past half year, 113,000 tons of tailing having been treated for about 28,250 tons of concentrate. These may be taken to average 42% zinc. The question whether the Delprat process is a modification of the Potter process is being fought out in the law courts, the Broken Hill Proprietary Co. defending the

negative view. The case will probably take years to settle, and in the meantime something better may come along.

The Broken Hill Proprietary balance sheet for the half-year ended May 31 is just out. It may be described as a marvelous document. Work was interfered with greatly by the fire in Block 11, and despite that fact, the company's net profits for the term were £232,332, against £196,959 for the preceding half-year, when full work was done and costs were lower. This increase is partly due to the fact that the company received £14 18s. per ton for its lead, as against £12 10s. 6d. in the preceding half-year, and 2s. 8½d. per oz. against 2s. 6½d. per oz. for silver, but the earnings from the zinc concentrate must have helped substantially. The company's financial position is very strong, as it has a surplus of £531,447 of liquid assets over liabilities, cash reserves of £225,000, and a suspense account of £60,000 cash to safeguard against reclamations should there be any fall in the price of spelter. The following table will illustrate better than anything else the extent of the company's operations, and the state of its finances:

	Nov. 30. 1904.	May 31. 1905.	Nov. 30. 1905.	May 31. 1906.
Ore produced, tons	325,000	292,827	307,830	230,968
Output.				
Lead, tons	35,552	35,627	37,487	20,320
Silver, oz	2,594,442	2,705,929	2,806,585	2,202,364
Gold, oz	1,273	1,563	1,511	1,130
Price obtained.				
Lead, ton	£10 14s.	£11 6s. 4d.	£12 10s. 6d.	£14 18s. 0d.
Silver, oz	2s. 4½d.	2s. 5½d.	2s. 6½d.	2s. 8½d.
Net profit	£136,261	£147,671	£196,959	£232,332
Do. per ton ore	4s. 5s.	5s. 11s.	£12 10s.	£20 2s.
Dividends	96,000	114,000	144,000	192,000
Depreciation	22,040	22,478	30,340	21,141
Reserve	125,000	150,000	150,000	200,000
Insurance fund	11,030	15,550	16,000	25,000
Surplus liquid assets	432,593	423,905	430,664	531,447

Toronto, Canada.

American Capital at Cobalt.—The Nipissing Bonanza.—Several Important Transfers.—Activity at Larder Lake.—A Copper Discovery.—Rich Ore in the Laurentian Mine.

The interest taken by American financiers and representatives of large commercial interests in Cobalt as a field for investment continues unabated, and several important transfers and amalgamations have taken place. The Cleveland Cobalt Silver Mines Co., Ltd., the promoters of which include S. W. Parsons and Frank M. Cook, of Cleveland, Ohio, has been chartered with \$1,000,000 capital to operate the properties of three amalgamated concerns, the Hudson Bay Extended, the Clear Lake Mining Co., and the Clear Lake Syndicate.—The Northern Star Mining Co. has sold to the Cobalt Silver Mining Co. for \$400,000 its location adjoining the Foster mine, carrying a vein of three or four inches wide of native silver. The shaft is only down a few feet, but the ore in sight is estimated at \$200,000.—The Bonanza vein at the Nipissing is now strictly closed to sightseers, unless they come provided with an order from headquarters at New York. About 80 men are at work stripping and trenching at this vein and 20 miners are getting out ore. On Thursday last week ore valued at \$100,000 was taken from this vein alone.

In the Portage Bay district, about six miles west of Cobalt town, the Evans property is being extensively developed, veins carrying silver and cobalt having been traced several hundred feet. One vein, rich in smaltite, has been discovered.—The McKinnon & McDougall location of 40 acres in this district, where free gold has been found, has been sold for \$50,000.—A syndicate, comprising A. C. Fowler Ross, Robert Mullen, and other Montreal capitalists, has bought the Godfrey property

near Gillies depot in the southern portion of the Cobalt camp, which has been for some time in litigation. They have also purchased the Powell property adjoining the White-Hargrave location, paying for the latter \$60,000. John Black, a returned British Columbia miner, will have charge of their operations.—At the Huronian Cobalt, in the southwest of the camp, a gang is at work stripping so as to disclose the surface ore. A 50-ft. shaft is being put down. J. J. Anderson is in charge as superintendent.

Great activity is being shown in prospecting operations at the new Larder Lake gold camp, where many fresh prospectors are arriving. Dr. Roddick, who found free gold here last summer, has refused an offer of \$75,000 for his claim, on which free gold has since been found in more than twenty places. The gold-bearing belt is from one-half to three-quarters of a mile wide. The field is nine miles from the railroad line and two days' travel by canoe from Haileybury or New Liskeard. A great rush

Map Showing Position of Cobalt and Lake Temiskaming.

is likely to take place next spring.—A valuable discovery of copper ore has been made by C. B. Duke and Dr. Campbell, two Rossland prospectors, three miles north of Bruce mines on the north shore of Lake Huron. Test pits have been sunk along the formation at intervals for a distance of three-quarters of a mile, and in all of them has been found ore of good quality.—R. B. Nickerson, who has had an extended experience in California, where he was for six years manager of the Confidence mine, has been placed in charge of operations at the Laurentian gold mine in the Manitou Lake area of northwestern Ontario. The force at this mine is still working on the rich ore of the 85-ft. level. It is claimed that the ore extends in depth from about 30 ft. below the surface to at least the 200-ft. level.—At the Golden Horn mine, Lake of the Woods district, a new Huntington mill has been installed and is now in operation.

It has a capacity of 40 tons of ore per day and is the first mill of its type introduced into that part of the country. —F. H. Clergue, of the Lake Superior Corporation, has gone to New York to raise \$1,000,000 to pay off the balance of the loan made to the company by the Ontario Government.

The Canadian Northern Railway interests are considering the establishment of large blast-furnaces and rolling mills in Toronto. They have asked the city for a 50-acre site on Ashbridge's Bay. The James Bay railway will next year be extended north to Moose mountain, where there are extensive iron deposits, 296 miles from Toronto. These are controlled by the Canadian Northern, and would be available as a source of supply.

London.

New Ventures in Cornwall.—Old Botallack to be Re-Opened.—Copper Mining in Ireland.—A Mexican Enterprise.—Deep Leads in Victoria.—The Kaffir Market.—Excessive Agency Expenses and Directors' Fees.

It appears that the Botallack mine is to be vigorously worked by a company in which the Cornish Consolidated Tin Mines, Ltd., will be the principal holders. This mine enjoyed the distinction of a visit by Her Majesty Queen Victoria in 1863. Her Majesty descended the incline shaft in a specially constructed 'gig', and in her wanderings underground went out under the bed of the Atlantic. The old mine has a good record. It is said that in one year one lode alone yielded tin to the value of £74,000. The mine has recently been inspected by several prospective members of the company to be formed, under the guidance of the manager (Mr. William Thomas), who is busily engaged in the preparation of a scheme for the working of the sett, which is considered to be a compact group of mines equal in importance to anything that is held by any one executive in the county. Another new proposition is the North Treskerby, upon which a party of local gentlemen are reported to have commenced operations. The public is not to be favored with an invitation to join until the developments warrant a general appeal. The property several years since was taken up by the late Baron Grant, who, however, did very little with it, notwithstanding the fact that he was promised considerable local support. The property is said to have a branch of the county adit running through it, giving some 35 to 40 fm. of 'backs', which, with the present price of tin, should conduce to the making of good profits. The continued boom in tin will have the effect doubtless of bringing other propositions to the front in "the delectable Duchy."

In Ireland, on the other hand, the Bonmahon Copper Mines, Ltd., is preparing to take advantage of the high price of the other metal, and Mr. Herbert T. Marks, the general manager, has been dilating on the outlook of the property. He reminded a press agent this week that from the thirties to the sixties of last century Ireland annually produced thousands of tons of copper, and the Bonmahon mines were by far the leading producers in the island. During the time it was actively worked the Bonmahon returned to its proprietors upward of £2,000,000 in copper. In 1868 this property was actually the biggest producer of the metal in the world. About 1870, with the appliances then available, the low price of copper, and certain labor difficulties, it was found difficult to work at a profit, and gradually the mines were closed down, and thus an important industry fell into decay. Mr. Marks is of the opinion that if the old company took out £2,000,000 between the surface and the 900-ft. level, the present company has an equally good chance between the 900 ft. and the 1,800-ft. levels, seeing that the orebodies

are running true at depth; the Government plans show that there are at least 2,000,000 tons still existing down to the 900-ft. level, and there is no reason why they should not go twice as deep.

Some of the promised after-the-holidays prospectuses are beginning to make their appearance. With the Consul for Mexico on the advisory committee, the Barranca Mines (Mexico), Ltd., has been formed with a capital of £160,000 in 160,000 shares of £1 each, to acquire, further develop, equip, and work the gold and silver mining properties situate in the Homosillo mining district of Sonora, Mexico, and known as Consuelo, Consuelo Extension, Las Goteras, El Capitan, Combinacion, Barranquita, and Ogden. The properties have been inspected by Mr. K. Dunbar-Anderson, who was instructed by Hudson's Consolidated, Ltd. In Mr. Dunbar-Anderson's opinion the mine is sufficiently opened up to justify the immediate erection of a reduction plant capable of treating 60 tons per diem; but the directors propose for the present to ship ore to the smelter already in operation within a distance of about nine miles from the mine. Taking the value of the ore at £9.12.0 per ton, cost of mining and reduction at £1.5.8 per ton, and allowing 10% for loss in recovery, a mining profit of £7.7.2 per ton is shown. Treating 60 tons per day for 280 days in the year would, it is anticipated, give a net profit on this basis of £123,620 per annum, thereby insuring substantial dividends. Labor, he reports, is abundant and cheap, and there is ample timber for both mining and fuel. The water supply is sufficient for all requirements. Anthracite coal of a good quality is also, he says, being opened up and worked within four miles of the property by the Southern Pacific Railway Co., and can be obtained at 20s. per ton landed at the mine, thus ensuring a fuel supply at moderate rates. Mr. Dunbar-Anderson adds: "There is, in actual sight and blocked out, in the mine over 15,000 tons of ore, which will average, according to my assays, £9 12s. per ton, making a total value of £144,000. In addition, there is on the surface about 30,000 tons of payable ore, varying from 30 to 85s. per ton, which was stoped out in former times." Mr. Anderson's statement on the labor supply will create a feeling of envy in one or two other companies that might be named operating in the Sierra Madre. It might even be called in question by managers in that region who are at their wits end to obtain an adequate number of work-people of the right sort.

Another deep lead share — New Junction Deep Leads, Ltd. — has been introduced to the notice of the public. The share capital is £80,000, in 320,000 shares of 5s. each, and there are issued 100,000 shares, on which 5s. per share has been called up. There are also 80,000 fully paid-up vendors' shares and a debenture issue of £20,000. The reserve for additional working capital is 140,000 shares. The directors are Messrs. H. C. Hadfield, J. A. Stoneham, St. John Winne, and W. N. Morrison. The company owns a property of 3,218 acres, situate between and adjoining the Victorian Deep Leads and Charlotte Plains properties. A shaft has been sunk to a depth of 325 ft. and a drift put in 718 ft. toward the lead. About 600 ft. remain to be driven to reach the lead. The mine is stated to be fully equipped with pumping machinery, and owns one-fourth interest in the Deep Leads Electric Transmission Co., which gives it ample power for working all its machinery. It is believed that the pumping operations already in progress on the adjoining properties will have materially decreased the amount of water to be dealt with. Active work is stated to be in progress at the property.

The mining make-up yesterday affords the usual opportunity for lamentations on the continued stagnation in Kaffirs. According to one would-be authority the lack

of direct control by shareholders on this side is a contributing feature. The enormous amount annually disbursed in the way of fees and management expenses has also a deterrent effect on investors. For instance, taking the Randfontein report, eight subsidiaries, it is estimated, have been drawn upon for over £13,777 in agency fees (London and Paris), and not less than the enormous sum of over £68,665 for directors and auditors. Besides, on the Block A and Mynpacht, there has not been much more work than a little boring, and for this work these enormous sums are paid in fees to directors and agents. The five producing companies—Robinson, South, North Porges, and Randfontein proper—show that the directors have drawn in one single year over £29,259, and there has been paid for agencies in London and Paris in that same year over £6,364. Lord Welby, presiding at the half-yearly meeting of the Standard Bank of South Africa, dealt with another phase of the subject. While acknowledging that gold and diamonds are the two staple products of South Africa, he held the opinion that "figures lately published bring to view the excessive overcapitalization of the gold mining companies and account for the unwillingness of the public to invest."

Calumet, Michigan.

Number of Men Employed in Lake Superior Copper Mines. — Scarcity of Labor. — Exploring on the Arcadian. — Retirement of Capt. Weir. — The Shafts at the Tamarack. — Fire Under Control. — Centennial Output Increasing.

According to the annual report of the mine inspector of Houghton county, the number of men employed in the mines at present is the largest in the history of the district. During the year ended September 30, the average number employed was 16,506, an increase of 1,251 over the previous year. In Ontonagon county 1,180 men are employed. Official figures are not available for Keweenaw county, which forms the third division of the Lake Superior copper region, but it is safe to estimate the total working force in that county at 2,500, which makes the grand total over 20,000. This is by far the greatest number of men ever employed by the Lake copper mines. Strange as it may seem, however, an actual scarcity of men exists and several mines are working shorthanded. So scarce is labor that the Adventure mine, at Greenland, in Ontonagon county, has been forced to resort to advertisements in the local press, wherein notice is given that work can be furnished to 50 trammers and laborers. There is need for 1,000 more men in Houghton county mines alone. Labor is so scarce that some of the managers have been forced to put trammers on drilling machines.

The use of Lake Superior capital in Mexico, Arizona, and Montana has caused great numbers of experienced men to leave this region to accept responsible positions in the newer camps. Many experienced men from here have gone also to the Cerro de Pasco mines in Peru, where they are occupying responsible positions. Notwithstanding the fact that every year a great many excellent miners come to the Michigan mines from Cornwall, England, there is constantly a scarcity of experienced men for supervision underground. While the scarcity of labor handicaps the managers and prevents the expansion of operations in some instances, it is not without its benefits, as it is an important factor in the remarkable strength which now exists in the metal situation. Lack of men prevents some of the Lake Superior copper mining companies from making a further increase in their output, and the same is true of the Bisbee mines, Arizona. Not only in the mines here, but in other fields

of work dependent upon the copper industry the shortage of labor is felt. Railroad construction in Ontonagon and Keweenaw counties is retarded. The Chicago, Milwaukee & St. Paul extension in Ontonagon is not advancing as rapidly as planned and there is need for 500 men there. The Keweenaw Copper Co., which is building the Keweenaw Central railway, has suffered from the need of laborers for several months past. The logging camps that cut timber for the mines will get out a reduced amount, because of lack of men and the high price of labor.

The sinking of No. 1 shaft at the Allouez mine has been resumed below the seventh level and the lode continues to carry excellent ore. The bottom drifts from No. 1 shaft are in good ground and the production this month will reflect the improvement. Since the extra head at the Centennial mill went into commission, the Allouez has been steadily increasing its ore shipments.

Herman Fesing, engineer of the Arcadian company is now engaged in surveying lines from the most recent disclosures of the Kearsarge amygdaloid bed on the Caldwell, Rhode Island, Teumseh, and the Franklin Junior properties, to ascertain the approximate strike of the lode across the Arcadian's lands. Some years ago the Arcadian conducted extensive diamond-drill explorations, but when the work was discontinued there remained 1,200 ft. untested. It is possible that the Kearsarge amygdaloid traverses this portion of the property. Mr. Fesing will also ascertain the strike line of the Calumet conglomerate across the Arcadian, as that lode was not positively identified in the drill-cores.

William Weir, for several years head mining captain of the South Hecla branch of the Calumet & Hecla Mining Co., has resigned, and will retire from active duty on November 1. Capt. Weir is a member of the old school of pioneer miners who were identified with the first development of Michigan's copper resources. He entered the employ of the Calumet & Hecla in 1872.

Construction work on the Chicago, Milwaukee & St. Paul railway extension southwestward from Ontonagon is retarded by the scarcity of men. Several contractors have crews working on their portions of the contract, and 500 more men could be used. As the new line penetrates a virgin forest, a great deal of work is required. It is expected, nevertheless, to have the line completed by the time winter arrives.

After several months delay, the Tamarack Mining Co. is now able to work without difficulty in the territory tributary to No. 2 shaft, which was closed down last January because of a fire underground. The ground in the vicinity of the shaft is subject to an enormous strain and is constantly moving to a slight extent by reason of the undermining, and this has thrown the shaft out of plumb. When the shaft was closed down about two years ago, to permit re-timbering, special provision to remedy the crushing was made by having the shaft in the rock extra large, while a timber shaft is constructed inside of this and is held vertical by means of lateral bracing. As the ground moves, this bracing is shortened or lengthened as required by the effort to keep the timber shaft straight.

No. 1 shaft of the Tamarack mine is still idle. It is unsafe to send men into it, as the fire has drawn off in that direction. This shaft does not ordinarily yield ore from the Calumet conglomerate lode, the ground in that formation tributary to it having been exhausted. It serves, however, to hoist the ore from the Osceola amygdaloid, which is reached by means of cross-cuts; consequently, the idleness of No. 1 shaft is not especially serious, although some good stopes were in operation on the amygdaloid, and it is of growing importance. The fire is burning among timbers in abandoned portions of

the mine and cannot possibly do any damage to the property beyond rendering No. 1 shaft idle. The shaft itself is separated from the zone of the fire by long cross-cuts, which are not timbered, and therefore it is impossible for the fire to reach it. After the shafts had been sealed for a week, the fire in the North Kearsarge branch of the Osceola Con. mine was extinguished, and work has been progressing normally in No. 3 shaft since that time. Additional forces will be employed and every effort made to overcome the shortage in output occasioned by the shutdown. The damage in No. 1 shaft, in which the fire occurred, was not as serious as was expected and the work of repairing the opening is being rushed.

Two lowest levels in both No. 1 and No. 3 shafts of the North Kearsarge branch are provided with concrete stringers for the skip-roads, and concrete was being introduced as extensively as possible before the recent fire. But there was a great deal of filling necessary in some of the old workings through which No. 1 shaft was sunk, and even if the wooden stringers were all burned, wood will have to be put in again to a large extent because the filled rock has not had time to settle solidly enough to provide a proper bedding for the concrete.

Centennial's production should show an improvement this month, as a better grade of ore is being stamped, and shipments have been increased since the extra head at the mill went into service.

Bisbee, Arizona.

Increased Capacity for Copper Queen Smelter Under Consideration. — Shattuck-Arizona May Build Smelter. — The Cochise Development Co.

The output of copper from the Copper Queen and Calumet & Arizona smelters at Douglas for the month of September shows a steady increase. The Copper Queen production during last month was about 8,200,000 lb. copper, and at the Calumet & Arizona 3,822,000 lb. were turned out. At the Copper Queen the work on furnace No. 10 is being rushed, and it is expected that it will be concluded by January 1. There is a steady increase in the amount of custom-ore shipped to the smelter each month, and the management feels that the extensive development work now being done in various districts surrounding Bisbee will justify the further enlargement of the plant.

At the Shattuck-Arizona, preparations for increasing the output are being pushed forward, and results show that they are effective. The report from the Copper Queen smelter for September shows that the Shattuck produced nearly a million pounds of copper during the month. B. M. Pattison, the superintendent, stated that he expects to be able to show a production of 5,000,000 lb. by the first day of the new year. There will be a meeting of the board of directors of the company held in this city early in November, primarily to discuss the matter of building a smelter. It is well known that a number of the directors are in favor of the proposition. Shipments to the Copper Queen smelter are averaging a little more than 200 tons per day, and are being increased steadily. The new Allis-Chalmers hoist is being erected, and should be in operation by the end of the month.

Work at the Cochise Development Co.'s property is progressing steadily, but no important results have been obtained as yet. The shaft is being sunk, and is still in an altered limestone formation. Reports from Tombstone are encouraging. The new pumping plant is working in a satisfactory manner, and the shipments are being increased. The management of the Butte & Arizona Co., operating in the Huachuca mountains, is favorably impressed with the orebody which was exposed on the property about two weeks ago, and are now making arrangements for the sinking of a shaft. Up to the present time the only work on this property has been the driving of an

adit to locate the orebody. It has been proved that the district contains copper, and the formation is almost the same as that of this district. The development of the Princeton group, which adjoins the Butte & Arizona, is progressing steadily.

Salt Lake, Utah.

Local Business.—Development of the Ohio.—Important Work at Ophir.—Improvements at the Cactus.—Heinze Is Active.—The Western Pacific Railroad. — Good Ore at Cold Springs.

The ore and bullion settlements reported by Salt Lake banks last week amounted to \$801,000. During the same period 483,705 shares of stocks were sold for \$183,853, as against 153,496 shares for \$53,076 during the corresponding period in 1905.

It is believed here that the option held by F. Augustus Heinze on a control of the stock of the Ohio Copper Co. will be exercised. Since the option was taken, early in the year, the mine has been undergoing careful and systematic development, resulting in the opening of some extensive bodies of copper ore. The Ohio is now looked upon as being one of the really big mines of Bingham. —The Markham Gulch Milling Co., recently organized, has the excavations for its Bingham mill nearly completed. This plant will treat ore from the Utah Apex and Utah Development mines.

The smelter of the Utah & Eastern Copper Co., at Shem City, Washington county, is treating about 40 tons of ore daily and making 7,000 lb. copper. —The Cliff Mining Co., operating at Ophir, is having some ore concentration tests made at the plant of the General Engineering Co., in Salt Lake, with the intention of constructing a mill early in 1907. A tramway is being built from the mine down to the town of Ophir. It is believed that W. A. Clark, who owns and operates the Ophir Hill mine in this camp, will build a railroad to the town of Ophir next year from St. John, a station on the main line of the San Pedro, Los Angeles & Salt Lake Railroad. The distance will be about nine miles. All but the last two miles can be built very cheaply.

The report comes from Ely, Nev., that excavations have been started for the mill and smelter to be built near there by the Nevada Consolidated and Cumberland & Ely companies. —The Newhouse Mines & Smelters Corporation, operating the Cactus copper mine in Beaver county, will install an electric hoist on the 600-ft. level of that property and sink in the orebody recently encountered. The management has also given orders for the construction of about thirty new cottages for the accommodation of a larger force of employees. Plans are on foot to develop this property upon a much larger scale than ever before attempted.

Although the Consolidated Mercur Gold Mines suffered an \$8,000 loss by fire last week, the management has given out the information that there will be no falling off in this month's output. The fire destroyed the mine carpenter shop and a building containing several electric motors used underground. The main mill-building was threatened for a time. —There are persistent rumors afloat that F. Augustus Heinze will exercise an option held on the Annandale at Tintic; this mine adjoins the Centennial-Eureka. Mr. Heinze has been in Salt Lake for several days, but is keeping his movements carefully guarded.

The Utah Copper Co. has a force of about 600 men engaged in constructing the mill at Garfield. While the equipment of the first section is in progress, good headway is being made with the foundations of the second unit. The steel structural material for the latter has begun to arrive from the plant of the Minneapolis Steel & Machinery Co. —Ore shipments have been started from

the Cedar mine, in Beaver county, where some large bodies of lead-silver ore were recently developed.—The Western Pacific Railroad Co. has filed maps showing the right of way of this new line from Salt Lake City west to Nevada. The route chosen goes north of the Gold Hill mine of the Western Utah Copper Co. in the Clifton district, or Deep Creek, about 30 miles. It is the intention of the copper company to erect a large plant, which means the construction of a branch line early next year. The road can be easily built, as the country is level all the way to the foot of Gold Hill mountain. This Deep Creek country is looking up, and all indications point toward much activity there during the next year.

It is claimed that 12,000 tons of ore of the value of \$50 per ton has been developed in the Jenny Mining Co.'s property at Cold Springs, Utah, of which Charles A. Short is manager. In a cross-cut from the 115-ft. level of the shaft a 12-ft. vein of ore was encountered, four feet of which is reported to assay close to \$100 per ton in gold and silver. This company has arrangements completed for the erection of a mill.

The Cactus copper mine in Beaver county, operated by the Newhouse Mines & Smelters Corporations, has come into considerable prominence lately owing to the opening of a tremendously large body of ore to the south of the developed portions of the mine. On the fourth level, the vein shows a width of 175 ft.; on the fifth level it has been cross-cut for 225 ft. without exposing either wall, and on the sixth, or tunnel level, a cross-cut is being pushed through the ore and is now in about 75 ft.; on the same level a diamond-drill has been sunk 260 ft. in ore of the same character. While the body contains much ore of a shipping grade, the mill stuff is said by Samuel Newhouse, the president, to contain at least 100% better values than that found in other portions of the mine. The mill is being supplied with ore from the 'glory hole' where the ore is broken by steam-shovel and dropped to the tunnel level and conveyed through that avenue to the mill, which is handling 800 tons per day and making a saving of about 85% of the values. The new strike carries more precious metals than the older developed orebodies.

Butte, Montana.

Exploring Outlying Territory Northeast of the Town.—Also in the Eastern Ridges.—The Discovery in the Bullwhacker.—Diamond-Drilling at the Cable.—Vigorous Development of Coalition Mines.—Production From the Speculator.

The Butte & Bacorn Co., largely financed at Pittsburg, is getting the shafts on the Belinda and Calumet claims, near the point where cross-cutting will begin, and the results of the work it is doing will go far to test the theory that the Butte copper deposits reach far to the northeast of the Butte hill, where the richest Amalgamated and Clark properties are situated. The Butte & Bacorn claims lie still farther to the northeast than the North Butte claims, whose remarkable discoveries proved that the theoretical boundary of the copper-producing region was by far too narrow. This company has reached the 500-ft. level with the two shafts just mentioned, figuring from the collar of the Belinda shaft, which is 60 ft. higher than that of the Calumet, the company having adopted the Boston & Montana Co. method of having a single system of levels for their various claims in the same group. When the 600-ft. level is reached a cross-cut will be run to the vein and the country will be explored. If nothing is found at this depth, sinking will be continued, at least to the 1,000-ft. level.

One of the most important ventures in the way of exploration of the country about Butte, is the Greenleaf shaft now being sunk by the Boston & Montana Co. This shaft is on one of a group of claims lying near the

base of the ridge east of the city. The shaft has already reached the 500-ft. level, where a station has been cut, and sinking has been resumed, the declared intention of the company being to sink to 1,000 ft. at least, and at any rate not to desist until thoroughly satisfied that there is no ore in the claims. These claims, like many others that lie along the base of the same ridge, and even well up on the slope, are crossed by strongly marked and wide veins. Several companies, including the Bullwhacker, Lewisohn Development Co., Butte & Summit Valley Co., Ida Montana Co., and others, are working in similar country along the base of the mountain, and a strike of rich ore in the Greenleaf group would mean much to the other companies.

Exaggerated reports have been circulated concerning a strike in the Bullwhacker claim. The truth of the matter appears to be that the cross-cut at 500 ft. was only started a month or so ago, and has not yet reached the main vein, the rich ore which was found being only a narrow streak detached from the main vein. There is no doubt, however, that the finding of this small body of ore is a good indication of mineralization at that depth, and the wide vein which lies beyond, and which is a part of the vein system that runs north and south along the base of the eastern ridge, may well contain orebodies of larger dimensions. Nothing of any commercial importance has been found, as yet.

The Cable Con. Mining Co., which has extensive placer holdings and quartz mines west of Anaconda, is continually milling the gold ore from its Cable mine, and is making ready to develop the copper lodes which were discovered by diamond-drilling in the bedrock below the gravel. The last holes put down with the drill show better in gold and silver than the others. — The Never Sweat mine of the Anaconda has again been closed down for a couple of weeks to allow of setting the hoisting engine, whose bed is on shifting ground on the foot-wall of the vein. The mine was closed for a short time last spring for the same reason.

A. T. Carson, manager of the Butte Coalition properties, says that the present policy of rapid development, rather than extensive mining, will be continued. The Nipper properties, belonging to the Coalition Co., and containing the much litigated Blue, or Nipper vein, are now being worked through the Parrot shaft. Mr. Carson says that the ore from the Nipper will continue to be raised through this shaft, which is capable of hoisting more ore than is now being taken out from the Parrot and Nipper combined. About 100 tons are being hoisted daily from the Nipper workings. The mine is only being worked on the 1,000-ft. level. The ore which lies between this level and the 500, has been tested sufficiently to show that there is a large body of commercial copper ore, enough to make the Nipper one of the most important mines in the district.

The Speculator shaft of the North Butte Co. is hoisting about 1,100 tons daily, for the most part first-class ore. Skip-chutes are in service on the 1,000 and 1,200 levels, and the chute on the 1,600 level will soon be ready for use. The development of the mine is still the main object of the working, and the output will be gradually increased from the ore already blocked out on the Jessie and Edith May veins. Within the year the Berlin will probably be yielding ore, and there is every reason to believe that the company will have a continually increasing output for many years to come, merely from the work now under way. — An Allis-Chalmers engine and hoist, a duplicate of the one soon to be installed at the Pennsylvania mine, has been ordered for the new Tramway shaft, from which the ore of the Minnie Healey and neighboring Coalition mines will be hoisted as soon as the shaft is deep enough.

Mining Summary.

ARIZONA.

YAVAPAI COUNTY.

(Special Correspondence).—An important discovery was made recently in the Swiss Girl claim, one of the Baumann Copper Co.'s group, situated about midway between Prescott and Jerome. The body of ore was encountered about a week ago, when a cross-cut was started from the 960-ft. level of the deep shaft after the second round of machine-drill holes was blasted. The cross-cut has already been driven a distance of 20 ft. without encountering a wall through the solid body of sulphide ore, which has been found to carry enough gold, silver, and copper, to ship the whole mass to the plant of the Arizona Smelting Co., at Humboldt, for treatment. A body of ore almost similar in character to this was found in the 500-ft. level, but the values at this depth were found to be not nearly as large as that of the new find. Work will be continued in the lower cross-cut until the walls are struck, when the work of opening it by a series of drifts and cross-cuts will be at once commenced, while the work of continuing the shaft to greater depths will be continued and the orebody exposed on the deeper levels. Encouraged by the extent and importance of the new discovery, the company has now under consideration the construction of a narrow gauge railroad from the Swiss Girl shaft to the Humboldt smelter.

Phoenix, October 20.

CALIFORNIA.

CALAVERAS COUNTY.

The new mill at the Hamby mine is now completed, and the stamps will commence to drop as soon as the transformers are in place so that the power can be turned on. There is an abundance of good ore to keep the mill running steadily. — The mining plant owned and operated by Albert Arents, of Alameda, situated about three miles from Copperopolis, has been completely destroyed by fire. The fire, of unknown origin, started about 8 o'clock, and laid in ruins the entire plant, consisting of a roaster, a five-stamp mill, and a cyanide plant, aggregating a loss of about \$20,000.

ELDORADO COUNTY.

The machinery for the French Hill mine has been received and the mine is working again after a short suspension. A Keystone drill is prospecting on the Broder place in the interests of the Blue Ravine Mining Co. If prospects hold good another new plant will be erected.

SISKIYOU COUNTY.

A large vein of ore was struck at the Snoozer mine on Russian creek by the Zarina Mining Co. recently, while they had men doing assessment work on the property. The vein is said to be of good size, and of a high-grade milling ore. — While working in tunnel No. 4 on the Blue Ledge mine, a narrow vein of quartz was encountered, about 80 ft. from the mouth of the tunnel from which was taken a mass of gold that weighed over \$7,000. — At the Seattle mine, there are about 80 miners at work at the mine and about 40 men employed surveying, grading, etc. — The hydraulic miners at Oro Fino, Quartz Valley, and other districts, are busily engaged in fixing up their apparatus and machinery, to be in readiness for operations as soon as the winter rains furnish a good supply of water.

TUOLUMNE COUNTY.

(Special Correspondence).—A contract has just been let for the driving of a cross-cut adit approximately 100 ft. at the Patterson mine. The adit will be 5 by 7 ft. Grading for a 20-stamp mill is in progress, and preparations are being made for installing a hoisting engine in the adit, 150 ft. from the mouth, where a winze will be sunk, and a raise is being put up. — The work of unwatering the Crystalline mine has been finished and a thorough inspection of the property for the Table Mountain Gold Mining Co. will shortly be made. It is expected that by Nov. 1 a large crew of men will be put to work. Driving south on the vein from the bottom of the shaft is contemplated and it is likely that the mine will be developed to a greater depth. — All hopes that

the water supply would last until the rains set in, were shattered early last week when the announcement was made that it was nearly exhausted. The stoppage of power came as announced, and as a result active operations were suspended at a number of the mines of the county. — Eighty men are employed at the Melones mine and the 100-stamp mill is kept in steady operation.

Tuolumne, October 22.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—Activity in mining increases each week in and around Georgetown. Surveys have just been completed for two new railroads; one will be a broad-gauge road from Denver to the Vidler tunnel, now being driven through the range under Argentine pass, and is called the Denver & Trans-Continental Railway Co. The other is the Santiago & Georgetown railroad, which will connect the Santiago mine with the aerial tram, now being built from the terminus of the C. & S. railroad at Silver Peak, and will enable the company to send down 50 tons or more of ore per day to its mill at Georgetown at a very low cost per ton. Passenger cars will be run in summer, affording sightseers over the loop and up the aerial tram to take in the rugged scenery of the range. At the Santiago mine, 25 tons per week of \$90 ore is sent to the mill by wagon. — The Denver & Trans-Continental Railway Co. was incorporated by Charles Baldwin, of Colorado Springs, and Rees C. Vidler, of Georgetown, with a capitalization of \$20,000,000. The road will be one of the scenic roads of the world, coming up Clear Creek cañon from Denver to Georgetown, thence around the mountains through the Vidler tunnel into the Horseshoe district, and on to Salt Lake and the Pacific Coast. This will open up the Horseshoe district, including Montezuma, Rathbone, Keystone, and Argentine, giving an outlet for its low-grade ore, of which there is a superabundance, and a much cheaper rate on supplies going in.

The main adit of the Capital Mining Co. is now in 4,400 ft. For the last 200 ft. it has been passing through a lode, the south wall of which has not yet been encountered. A three-foot vein of lead and iron pyrite was cut this week which assays \$30 per ton, alongside of this is 12 ft. of fine mineralized quartz. The adit will be pushed ahead till the other wall is reached. — B. J. Martelon & Co., of Idaho Springs, recently took hold of the old Pulochi mine on Leavenworth mountain, which was a large shipper years ago. They shipped a car of concentrating ore which gave most satisfactory results. The old workings will be opened and put in shape with all speed. The lessees on the Lebanon who have been shipping \$40 ore made a strike of \$200 ore last week. — Tom Cunningham, working the Queen of the West has encountered good ore but is still driving the adit ahead to come under the old ore-shoot from which ore milling many hundreds of ounces in silver per ton were taken. — The Krupp Mining Co., operating on Beaver gulch cleaned out an old adit on the property and at 250 ft. in opened up four feet of ore assaying 100 oz. silver per ton.

The Two American Sisters Mining & Power Co. has encountered a large orebody in the lowest workings, which assays high in silver. This company's power-plant below Georgetown is rapidly nearing completion. It has also purchased a concentrating mill at Empire which is now being torn down and transferred to the mine at Silver Creek. — A cave in the roof of the adit on the Maude Carrie disclosed five inches of ore which assayed 53 oz. silver and \$7 in gold per ton.

Georgetown, October 22.

Another good strike has been made in the Wilcox tunnel of the Waldorf Co.'s property, the ore being found in a vein that was cut in the tunnel at a distance of about 1,900 ft. from the portal. Driving was recently commenced on this vein and this has resulted in opening a fine body of ore carrying gray copper, silver glance, and peacock copper, and having a value of several hundred dollars per ton. As this vein has been cut at a depth of 360 ft. from surface it gives a large block of stoping ground. In addition to about 15 in. of this high-grade smelting ore there is about two feet of concentrating material in the lode.

LA PLATA COUNTY.

(Special Correspondence).—This district has shown increased activity during the past few months and the prospects for a good winter are encouraging. The May Day, which is owned by A. E. Reynolds and associates, of Denver, is one of the bonanza mines of the State. They are shipping about two cars of ore per day from this property. —The Bonnie Girl Co. has closed down the mill on account of repairs. The foundations for the stamp-batteries were made of concrete, but, on account of the lateness of the season in which the work was done, they did not prove satisfactory. The concrete is to be replaced by timber foundations. —At the Durango Girl a rich shoot of ore is being opened up. This mine is to be equipped with power-drills. —The Tomahawk Mines Co., of which E. H. Lunken is president, and Geo. W. Gilmore, treasurer, is doing development and prospecting work. The adit, which is now some 350 ft. long, is being driven as fast as possible by Temple-Ingersoll drills. About the 500-ft. mark they expect to cut the Tomahawk and Clyde veins, which were located in the early eighties. The ore from the workings at the surface assays from \$10 to \$200 per ton. The adit will cut these veins at a depth of 600 ft., and by driving a distance of 1,000 ft. can be gained.

La Plata, Oct. 20.

SAN JUAN COUNTY.

At Gladstone the Gold King mill, under the management of W. Z. Kinney, has been overhauled and Card tables put in place of vanners and slime-tables. The extraction made by this plant is considered most satisfactory. —F. W. Bosco has charge of the big Mogul mill, which he hopes to have running at full capacity within a few weeks. The mill consists of 40 stamps, of which 15 are in operation at present. One car of concentrate is being made daily. The concentrating part of the mill is composed of Card and Wilfley tables and Blake magnetic separators. The product is lead, zinc, and iron.

The Big Colorado on the south fork of Cement creek, about one mile from Gladstone, is being developed under the management of C. W. Bloodgood. The Adams electric drills are being used in the tunnel work. Across the gulch, the Natalie Co. is re-constructing its power building which was injured by snowslides last winter. —A short distance below the Gold King and Mogul mills, the Henrietta Co. is doing considerable work and making shipments. —Farther down the gulch on Cement creek, A. A. Lamont is developing his property and preparing to ship a car of ore. —Near the mouth of the canyon and on the line of the branch railroad from Silverton, the smelter is being operated by the Ross Mining & Smelting Co. on ore from its own mines as well as custom ore.

T. R. Henahen is still doing development work on the North Star and hopes in the next few months to be in a position to start the mill. —Thomas Kane, manager of the Hercules Mining Co., is overhauling his mill, and has suspended development work in the mine until the mill is ready to run. —Cunningham gulch is the scene of much activity. The Highland Mary, near the head of the gulch, is operating at present. The mill belonging to this company is idle. The new mill of the Green Mountain Co. is in charge of C. J. Garvin, formerly superintendent of the Portland mine at Cripple Creek. Several changes are being made in the mill, which is credited with a capacity of 120 tons per day. About 100 tons are being treated at present. It is Mr. Garvin's intention to install electric power shortly because it is quite expensive to operate with steam, although coal can be delivered at the mill by rail. The power will be secured from one of the big power companies. The mill is connected by aerial tramway with the mine.

SUMMIT COUNTY.

Several tests are being made at Denver by various magnetic separating machines on the zinc-iron concentrate of the old Union mill. When it has been decided which is the best machine for this work, two or more of them will be shipped to Breckenridge. J. B. Sherwood, of Ripon, Wis., who is the treasurer of the company, has been at the mine, accompanied by Dr. A. H. Abbott, of Oshkosh, another director. The Blue Flag on Bald mountain is now

running and good returns are expected from the first clean-up. —J. Parke Channing, of New York City, has been at Breckenridge for some days investigating the results of the drilling tests on The North American placers along the Swan river. This is being done with a view to a purchase of the property by New York and London capitalists, clients of Ben Stanley Revett, the noted hydraulic engineer. —The Oro Grande placer, at Dillon, ten miles west of Breckenridge, is now under option to the Summit Banner Placer Co. —W. W. Wonsor, secretary of the Square Deal Co., has been making an official visit to the property in order to report on the latest developments. —The Four Most mine on Chief mountain, at Frisco, is likely to change hands shortly. A syndicate of Denver men is now considering the purchase of this property, which has been a good producer in the past. —Francis L. Judd and associates, of Topeka, Kansas, have purchased some valuable property adjoining the Square Deal mine. The claims show good outcrops of copper ore. —A deal on the Masontown mine and mill is now in hand.

TELLER COUNTY.

The Aileen mine is now shipping at the rate of from ten cars per week to two cars per day. Nine machines are engaged in breaking ore in the 600-ft. level, the product being shipped without sorting and averaging \$30 per ton.

IDAHO.

SHOSHONE COUNTY.

The new 200-ton concentrator at the Success mine will start work in the middle of next week. This mine contains two great bodies of ore which are known respectively as the foot and hanging-wall ore-shoots. One has been proved to be over 200 ft. long on the No. 3 tunnel level, where it has an average width of fully 12 ft. It has also been opened up for the same length in three intermediate levels, 100 ft. apart, between the No. 3 tunnel and the old workings, 460 ft. above. In the first of these levels the ore-body is over 50 ft. wide at one point and for the greater part of its length it averages over 25 ft. in width. —The winze being sunk on the Charles Dickens, on Moon gulch, near Wardner, is exposing some fine galena ore. There is a double-compartment shaft sunk on this property to a depth of 152 ft. From this level, A. D. Birtman, who holds an option on a majority of the stock, is sinking a winze on the vein. He is down 70 ft., where he has just completed a cross-cut of 12 ft. on the vein and but one wall in sight. In this 12-ft. cross-cut there is at least 20 in. of solid galena ore, while the balance of the vein is good concentrating ore. Assays made on samples from this cross-cut run 65 to 78% lead, giving a half ounce of silver to one per cent of lead. The 50-ton concentrator ordered by Mr. Birtman some time ago was shipped the first of the week.

NEVADA.

LINCOLN COUNTY.

(Special Correspondence).—The electrical machinery for the plant which is to furnish light for the entire camp, as well as Searchlight, is all installed with the exception of the dynamos which are being hauled by team from Manvel and within the next week the plant will be in full operation. The railroad camps are plainly visible from Searchlight, and the grading and track laying is rapidly being pushed toward completion. The Eldorado Canyon district and the new Thurman camp at Newberry mountain both tributary to Searchlight show increasing activity. The hospital for the accommodation of the sick and disabled miners of the district is being much improved under the direction and supervision of the Mine Operators Association. —The Gold Dyke Mining Co. is making contracts for the erection of a hoist and the sinking of the shaft to deeper levels. Assays run as high as \$60 per ton. The property adjoins the Pompeii and the Blossom, \$317,000 having been taken out of the latter mine within 50 ft. of the surface. From all appearances the Gold Dyke will make one of the large producers of the district. —On the Colorado M. & M. Co.'s shaft they have struck some water at 215 ft. but not enough to necessitate a pump, however. H. Adsit, the manager, has contracted for pumping machinery in case the occasion demands it. The shaft is double compartment;

the showing so far is excellent.—Contract has been let for a 100-ft. shaft on the Golconda, which is located near the Yellow Rose and Gold Dyke; the work is already under way.—The Cyrus Noble Extension shaft at a depth of 180 ft. finds the orebody steadily increasing in size and quality.—The Duplex, the first mine located in the camp, is working day and night with a force of 72 men. They are cyaniding the tailing, which runs between \$5 and \$6 per ton. The cost of \$1.12 leaves a net profit of between \$4 and \$4.50 per ton.—The Nevada Consolidated in the McGhan camp has one hoist in operation. The shaft at 260 ft. has encountered another new orebody with a width of four feet, assaying as high as \$60.—A new map of the Searchlight mining district has just been issued by Stone & Brown, Inc., mining engineers and U. S. Deputy Mineral Surveyors, and as it is made up directly from survey notes, its accuracy is a noteworthy feature. The new map shows over 500 claims in a territory slightly more than five miles in length and somewhat less than five miles in width, taking in the larger part of T. 28 S., R. 63 E., Mt. Diablo B. & M. in the northern portion of T. 29. It is drawn on the scale of 800 ft. to the inch.

Searchlight, Oct. 22.

(Special Correspondence).—Representatives of the Occidental & Oriental Wireless Co. of the Pacific Coast have been in Searchlight for the past few days making arrangements preparatory to installing a wireless telegraphy station.—Last week there were many sensational discoveries of orebodies in the outside districts, thereby enlarging the generally recognized mineral belt. Reports from Newberry mountain are very encouraging, and the first shipment of ore from Camp Thurman has been made to the Salt Lake smelters. In Eldorado Canyon ore was struck on the Eagle group, owned by W. J. Kennedy, adjoining the Capitol mine, assaying 3,000 oz. silver per ton. On the 'Flat' west of Searchlight, strikes were made on the Wyoming-Searchlight in the shaft at a depth of 209 ft., on the Sunny Jim in an open-cut, and on the Searchlight-Vanina in a drift from the working shaft. At the bottom of the shaft in the Annette, in the foot-wall, at a depth of 150 ft., specimen ore was struck. This snug little acreage adjoining the Southern-Nevada has ore that has assayed as high as \$200 per ton.

Two miles northwest of Searchlight, in the immediate vicinity of the estate of the Searchlight Mining & Milling Co., lies the Sunny Jim group, owned by the Sunny Jim Mining Co. This group consists of the Sunny Jim, Sunny Jim, Jr., Talco, Big Horn, and Old Charter claims. At the bottom of a 30-ft. shaft on the Sunny Jim, a large body of ore has been opened up that gives an average assay of \$8 in gold. The values on this property are very uniform, and have been found in every cut opened on the four parallel veins. There are three distinct veins traversing the Sunny Jim claim; the surface assays run as high as \$56.—Fredericks & Co. have taken a contract to sink a shaft 5 by 7 in the clear, thoroughly timbered to water-level.—Development is proceeding very rapidly on the Duplex Extension, adjoining the John Brockman mine. Superintendent Eschenhardt is sinking the shaft on the Euchre claim and has almost reached the 100-ft. level. The vein is widening and the values increasing as depth is being attained. At present the shaft is down 96 ft., and the vein is five feet wide, dipping at an angle of 45%. The vein is oxidized and heavily mineralized with iron, with a talc seam next to the hanging wall carrying gold values. Everything in the shaft gives hornings. A gasoline hoist will be installed at once, as depth has almost outweighed the carrying capacity of the windlass. Bunches of ore have been encountered in the shafts on the Regal and East Side claims, carrying values in gold and galena. Systematic development is being prosecuted and the management will have three shifts at work after the hoist is installed.

The Little Eldorado Mining Co. has resumed development work on the property of the company in the cañon this week. John Howe has taken a contract to sink a shaft to water-level, also to do an additional 500 ft. of underground work. The company owns the Little Eldorado, Thelma K., Keystone, Western, Red Butte, and Soldier Boy claims, and 120 acres of placer ground, together with a mill site.

Assays have been received as high as \$225 in gold from the shaft on the Soldier Boy claim. A townsite has been laid out, platted, surveyed, and patents applied for. The new town is known as Nelson and already has a post-office and telephone station. The latter has wires to the Venus, Black Hawk, Eldorado-Nevada, Combination, Silver Sphinx, and the Kennedy camp, besides a long-distance line to Searchlight, Nippon, and Barnwell.

Searchlight, Oct. 24.

SOUTH DAKOTA.

CUSTER COUNTY.

Custer seems to be the centre for the black sand interest which is still kept up, and many locations have recently been made covering the old and worked-out placer claims in the district. Quite a number of small sales have taken place, the most notable of which has occurred in Tenderfoot gulch, about six miles north of Custer, where one-third of a claim was sold for \$1,500. The values vary, but it has been ascertained that all the black sand in this district will yield a profit when properly treated. The method employed is concentration and cyaniding the concentrate.

The Ivanhoe, eight miles northeast from Custer, is the only mill running in the county at the present time, yet there is more energy displayed in the line of development than has been observed for several years. There has been no less than five different groups of quartz mines in this district sold (under bond) during the past month.—The Saginaw Co. is still driving on the 400-ft. level and has lately passed through two veins of ore, the one 14 ft. and the other 8 ft. in width, the larger vein being of a good grade, and the lesser one said to be very rich in gold, much of which is free, and the remainder in the form of sylvanite and bismuth telluride. In the new mill soon to be erected L. P. Woodberg has concluded to adopt the 'National ore pulverizer' instead of stamps.—Supt. Millham has put a crew of miners at work on the Interstate group of mines, seven miles northwest from Custer. They are sinking on the main shaft, which carries a vertical vein of quartz of good grade 8 ft. in width.—Supt. Moyer of the Girtle mine, near Hill City, is improving the method of concentrating the cassiterite taken from the mine.

The Clara Belle mine is still mining and milling ore from the old shaft at a good profit while it is sinking a new working shaft, which is now down a little over 100 ft. They expect to strike the large orebody (which is of high grade) in a few days.—J. Guertin, connected with the Westinghouse Electric Manufacturing Co., returned from the East a few days ago with five families of children of suitable age to work in the mica factory, to help in the mine, and in the mica splitting and trimming department. They require 100 at present and expect to employ 200 as soon as they get their new factory built, which will be some time next spring. F. N. Myers is superintendent at this place.

The Ochre mill, which has not been running since the death of the owner, Henry Robinson, is now ready to resume operations with full capacity.

It is reported that the Extreme Mining Co. will resume development on its property in a short time. They have a ten-stamp mill on the ground which ran for a while, but closed down on account of the refractory character of the ore.

UTAH.

SALT LAKE COUNTY.

I. T. Long & Co., owners of the Basin mill, has leased the Tornado mine, or that part of it known as the Indiana vein, which crosses the main Tornado tunnel at a depth of 150 ft. In addition to the work of the lease on the cross-vein, the company will continue the main tunnel to eat the Tornado vein, which parallels the Indiana about 400 ft. to the south.

WASHINGTON.

FERRY COUNTY.

A recent strike in the Gwinn mine, east of the Sherman range, on the Columbia river, shows ore 14 ft. wide that assays \$6.19 gold, 23 oz. silver, and 9% lead. On the north and south extension of the Gwinn, two groups of claims

have been sold to a Tacoma syndicate for \$20,000 and \$15,000 respectively. A strike of ore three feet wide has been encountered on one of them and appears rich.—The Silver Creek Mining Co., five miles east of Keller, on the Gold Cord mines, is driving an adit, on two shifts, to strike the vein 304 ft. deep and connect with a winze, at the bottom of which the vein is seven feet wide, with two and one-half feet of shipping ore. This company is a twin corporation of the Keller & Indiana Con. Smelting Co., and has contracted to send all of its ore to that company's smelter.—The Lorraine Copper Co. has contracted for delivery of 1,000 tons of ore from the Malachite claim to the same smelter, and will resume work on it immediately for that purpose.—At the Iconoclast mine an adit has been driven 175 ft. on the vein, which carries an average of three feet of ore for that distance, and spots of native copper have been observed all through it.—A cross-cut from the bottom of the shaft on the Umatilla group has intersected 14 ft. of shipping ore. A tunnel has been already driven 120 feet.

On Dick creek, west of the Sans Rail river, an important lode has been discovered by Charles Fogarty, an old Comstock miner, cropping 180 ft. in length and 24 ft. in width. The ore is said to be principally iron oxide in a purple quartz gangue, and assays in gold, silver, and copper.

The Orient mine has been closed down because of disagreement among the directors of the company.—The Gwinn mine has been bonded for \$10,000 and two payments made. In a shaft 150 ft. deep the vein was found to be faulted on the 100-ft. level. From the bottom of the shaft a cross-cut was driven eastward 67 ft. and the vein found. In a drift 70 ft. south from the intersection some good gold-silver ore was found. A winze was started on it, but was abandoned on account of impure air. An adit is to be driven to tap the vein about 550 ft. below its apex and 140 ft. below the bottom of the shaft.—The Anonymous shaft was sunk 30 ft. on quartz of low value and then abandoned. Work has since been resumed on the lower adit.

The Oversight Mining & Milling Co. is advertising for teams to haul ore to the Belcher Mountain railway.—A shaft has been sunk 70 ft. on the foot-wall of a 12-ft. vein on the North Star mine. The ore assays from \$20 to \$36 per ton. An adit has been started to tap the vein 130 ft. deep.—The Humboldt Mining Co. has let a contract for driving the adit another 80 ft. It is expected the vein will be encountered at that distance about 450 ft. deep. A shaft was sunk 25 ft. on the vein and ore uncovered which assayed from \$63 to \$80 per ton in silver and lead.—At the Umatilla mine a shaft was sunk on ore which averaged \$45 per ton in gold and copper. Assays run as high as \$80 per ton. The adit under way is expected to strike the vein 180 ft. from the portal and 150 ft. deep.—An adit has been driven 20 ft. on a body of ore in the Copper King mine, but did not pass through it. Another adit has been started to tap it at a depth of 70 ft. The ore is rich in silver and copper.—Ore, supposed to be wolframite, has been found near Keller, at the head of Copper creek. An adit has been driven across it 20 feet.

The Belcher Mountain railway, nine miles long, running from Belcher spur on the Great Northern Kettle river branch, near Curlew, is completed. A surface tramway, with a capacity of 600 tons of ore per day, is being constructed to carry the ore from the mine to the railway.

OKANOGAN COUNTY.

The Copper World shaft has been sunk 135 ft. on the vein. The manager reports a continuous body of ore.—The O. S. Mining & Smelting Co. has elected as trustees for the ensuing year. A. M. Dewey, president; M. L. Bevis, vice-president; C. L. Shuff, secretary; E. J. Hyde, treasurer; L. K. Armstrong, consulting engineer. There were 1,900,000 out of 2,000,000 shares represented. The company has 567 shareholders of record. The president reported the payment of debts amounting to \$6,000, and an expenditure of \$16,000 on the mine during the past year. An electric power plant is being installed. Hand-drilling has been discontinued, as the compressor plant is nearly ready for machine-drilling. During the coming year the company will drive a new adit to give 1,500 ft. of depth below the present lowest workings.

STEVENS COUNTY.

The Panhandle Mining Co., of Idaho, has purchased the ore-dumps of the Queen, Providence, Deertrail, and Silver Seal mines, containing tungsten. The mines are situated in the Cedar Cañon district, in Stevens county. It is reported that the Krupp Government Gun Manufacturing Co., of Germany, has purchased five tungsten claims in this district.—The First Thought Gold Mines Co., Ltd., has contracted to deliver 1,500 tons of ore per month to the Northport smelter as soon as the latter starts up.—The Mammoth Silver-Lead Co. has driven an adit from the Pen d'Orielle river bank into a body of ore, mostly galena, tapping it 90 ft. deep.—The United Copper Mining Co., of Chewelah, is driving an adit 600 ft. in length to connect with a shaft at a depth of 120 ft. The shaft, a single compartment, is being enlarged to a two-compartment. A cross-cut on the 100-ft. level shows the vein about 25 ft. wide, with ore assaying 12% copper. A steam-hoist and plant for steam-drills are being installed, and two shifts will work all winter. New office, bunk and boarding houses are being erected.

MEXICO.

The American Smelting & Refining Co. has blown in the first two furnaces of its copper smelting plant at Valardeña, Durango. Others will be blown in from time to time. The capacity of these two will be from 350 to 400 tons per day. This smelter is planned to be as large as any in Mexico.—The Pinguico mine, in the Guanajuato district, is now producing from \$15,000 to \$20,000 per week. The bulk of the ore is being shipped to the smelters, and the remainder is being treated at the Central plant. An adit is being driven through the adjoining Carmen property of the Guanajuato, Con. Mining & Milling Co., and this will give an additional depth of 200 m. in the Pinguico. The adit is being driven for the joint account of the Guanajuato Development Co. and the Guanajuato Consolidated.

PARRAL.

It is stated that a 100-ton reduction plant will be constructed at Parral for the treatment of custom ore. The syndicate proposes to make a flat rate of \$5 per ton, which will render available a large tonnage of ore on the dumps. By the beginning of next year the 250-ton cyanide plant of the Veta Colorado Mining Co. should be completed. This will be the first cyanide plant in the Parral district, and if it proves a success, another 1,000-ton custom plant will be immediately erected.

BRITISH COLUMBIA.

OUTPUT OF MINES IN THE BOUNDARY DISTRICT, B. C., FOR WEEK ENDING OCT. 21.

Mines.	Tons.	Mines.	Tons.
Brooklyn	2,706	Rawhide	792
Centre Star	25	St. Eugene	750
Emma	24	Snowshoe	745
Granby	13,669	Strathmore	53
Idaho	330	Sunset	757
Iron Mask	150	Ymir	22
Le Roi	2,940	Smelters.	
Le Roi No. 2	90	Granby	9,743
Mother Lode	1,800	B. C. Copper Co.	2,676
Mt. Rose	100	Dominion Copper Co.	4,687
Providence	121		

The work of developing the mine and of installing the new machinery at the Centre Star continues. The recent shipments from the mine were of ore extracted in development. The sinking of the shaft between the twelfth and thirteenth levels continues and good progress is being made. The construction of the head-frame for the new hoist is progressing. The old War Eagle compressor-plant will soon be in position, as the foundation is ready for it. There is considerable advance work to be done in the mine, and the company will endeavor to keep the larger portion of its employees busy during the time the Trail smelter is shut down.

At Le Roi No. 2 the re-timbering and repairs to the shaft continue, and this task will occupy about three weeks. The machines are kept at work breaking ore. No development work is in progress, for the reason that waste cannot be hoisted while the shaft is under repair. Shipments from Le Roi are up to the average. No more ore will be sent to Trail until a supply of coke has been received, but shipments will be made to the Northport plant, where the ore will be accumulated for the present.

Personal.

HORACE G. NICHOLS is at London.

ERNEST A. WILTSEE is at Mexico City.

S. HERBERT WILLIAMS is at Ely, Nevada.

EDGAR RICKARD was married on October 24.

THEODORE F. VAN WAGENEN is now at Phoenix, Arizona.

E. MAY of Lead, S. D., has returned there from Nevada.

J. M. ILES is on his way from London to Coquimbo, Chili.

W. E. CONDON is engaged in railroad surveying near Ely, Nevada.

H. L. SWAN is visiting the Paymaster mines near Tucson, Arizona.

LEO VON ROSENBERG has returned to New York from Georgia.

PHILIP L. FOSTER has opened an office at 111 Broadway, New York.

DUNCAN CHISHOLM has returned to Colorado Springs from Nevada.

JOHN S. MACARTHUR is examining the Fresno copper mine, in California.

C. S. RICHARDS, of the Nundydroog mine, is at London, on a visit from India.

C. L. BLACKMAN, of Denver, is at Silver City, New Mexico, on mining business.

MERRILL A. MARTIN, of the San Francisco Mint, has returned from Colorado.

CLAUD HAFFER is superintendent of the Gatewood Mining Co., at Howard, Oregon.

GOMER THOMAS, State Mine Inspector for Utah, has returned to Salt Lake from Denver.

GEORGE L. EDDY has accepted a position at the Densmore mine, Columbia, California.

T. JOHNS RIGBY is at Chicago and expects to be at Mayer, Arizona, within the next ten days.

F. B. REECE has gone to Mexico as assistant to H. H. WEBB in the examination of mines.

FRANK PROBERT, of Los Angeles, has been examining mines in Amador county, California.

GEORGE H. EVANS has returned from examining mines in the States of Puebla and Oaxaca, Mexico.

HENRY BRELICH, general manager of the Anglo-French quicksilver concession in China, is visiting London.

F. F. SHARPLESS passed through El Paso on his return from the Sahuayacan district of Chihuahua, Mexico.

THE Geological Survey was represented at the Mining Congress by WALDEMAR LINDGREN, J. A. HOLMES, and E. W. PARKER.

H. S. CLARK, western manager for the Lanyon Zinc Co., and WILLIAM ROGERS, managing director, were at Breckenridge, Colo., recently.

ROBERT H. RICHARDS has returned to Boston from New York, where he was in consultation in regard to a concentrating proposition on the Pacific Coast.

STANLY EASTON, manager of the Bunker Hill & Sullivan mine, at Wardner, Idaho, has been on a visit to San Francisco, to attend EDGAR RICKARD's wedding.

A. B. W. HODGES, for three years superintendent of the mines and smelter at Granby, has been appointed local manager for the company, with headquarters at Phoenix.

THE Exploration Co., Ltd., has opened an office in the Trinity Bdg., New York. P. L. FOSTER, the mining adviser of the company, will be resident manager of this office.

AMONG those who attended the Mining Congress at Denver were W. R. INGALLS of *The Engineering & Mining Journal*, R. L. HERRICK of *Mines & Minerals*, and KIRBY THOMAS of the *Mining World*.

A. N. SPENCER, technical engineer of the Harbison-Walker Refractories Co., Pittsburg, Pa., has just returned

from a six months' trip among the smelters in Mexico, the Southwest, West, and British Columbia.

JOHN B. FARISH and GEORGE J. MCCARTY have resigned as consulting engineers to the Dolores Mines Co. and the Mines Co. of America to devote the whole of their time to the Mines Finance Company, of New York.

PHILIP ARGALL, D. W. BRUNTON, GEORGE E. COLLINS, J. W. EDWARDS, G. C. HEWETT, ARTHUR LAKES, MARK R. LAMB, H. R. PLATE, GEORGE J. BANCROFT, and H. A. SHIPMAN were among those who attended the recent session of the Mining Congress at Denver.

J. M. BOUTWELL, geologist, United States Geological Survey, who has recently been placed in charge of statistics on the production of zinc, lead, and quicksilver in the United States for that bureau, was confined during the summer to St. Luke's hospital at Denver by typhoid fever. He is now visiting various points in the West in connection with this work, but owing to loss of time by his sickness will be obliged to postpone some of his itinerary for the field investigation of the resources of these minerals until the next field season.

THE CALIFORNIA PERRIS COMMISSION having received applications to mine by hydraulic process from Ah Woe Co. in Rocky Point Placer Mine, near Gold Run, Placer County, California, draining into Canon Creek; and from J. L. Zuver, Sr., in Wallace Canyon Consolidated Mine, near Long Canyon, Placer County, California, draining into Wallace & Long Canyon, gives notice that a meeting to receive any protests will be held at No. 1733 Pine Street, San Francisco, Cal., November 12, 1906, at 1:30 P. M.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

PLATINUM is confined to basic rocks ; in Russia and in British Columbia it has been found in peridotite. Formerly it was supposed to occur only in placers.

BARYTES is used as an adulterant for white lead and is added to paper to give it weight. It is often bleached by being boiled in acid to remove the iron stains.

THE average weight of a good four-ply rubber belt, 7 in. wide, is 16 oz. per linear foot. The best rubber belting is made with 32-oz. duck, and then weighs 20 oz. per linear foot.

VENTILATION PIPES of oval section are often more convenient than round ones having the same capacity. These pipes occupy less space in the drift or shaft and the extra friction is of no account.

GUNPOWDER is used in quarrying slate, as it is necessary to have a rending and not a shattering effect. When high explosives are used, it spoils the slate for many feet, though it may have little or no visible effect.

THE greatest item of repairs in connection with a belt-conveyor is the replacement of the belt, which is the most costly single piece of the apparatus. If the belt lasts five years, the cost of repairs will come to about 12.5 % per annum.

In a concentrating mill, the ore from different parts of the mine should be mixed to ensure a uniform standard. This is important, not only because it insures even working of the machinery, but because one can judge better of the performance of the mill.

ADEQUATE VENTILATION is one of the best preservatives for timber. A steamy atmosphere may rot 12 in. Oregon pine in six or eight weeks. Timber with cold water dripping on it will last longer than that in a dry drift, as the spores of dry rot are washed off the wet sets.

THE amount of power needed to run a concentrating mill will vary according to the size of the mill, as follows:

15 to 30 tons capacity daily, 1.50 h.p. per ton of ore treated.	
50 to 75 " " " " " " " "	1.25 " " " " " "
100 to 120 " " " " " " " "	1.00 " " " " " "
200 " " " " " " " "	0.75 " " " " " "

A SPEED of about 300 ft. per min. is commonly given to belt-conveyors, but 450 is not excessive. Belts have been known to run smoothly at a speed as high as 900 ft. per min., but the wear on both the belt and the idlers then was excessive and so high a speed is not recommended.

THE surveying of claims for patent from the United States Government can only be obtained by those who have received appointment of United States Deputy Mineral Surveyor, and they must have an order from the Surveyor-General of the State or Territory in which the claims are located before making any such survey.

MOISTURE in air-compressors is often the cause of a good deal of trouble. In the case of a compound compressor, this may be caused by suction through the drain-pipe of the cooling chamber between the cylinders, if it dips below the surface of the conduit into which it drains. If the compressor is provided with a governor on the air-intake pipe, it will take air until the required pressure is

obtained, after which the intake valve closes and the compressor runs under high vacuum so that suction takes place. If this is the case it can easily be detected by the fact that the low-pressure cylinder will be dry, while water will be found within the high-pressure cylinder and the receiver.

A NEW application of wolfram is reported from Germany. The Osram electric lamp, in which the carbon filament of the ordinary glow lamp is replaced by fine wires of wolfram, is said to use only one-third of the energy required with glow lamps. A test of 1,000 hours gives a loss of brilliancy of only 3.6 % in a 32 c. p. lamp.

AN experimental gas turbine has recently been constructed in France, which under test showed an efficiency of 18 %. The turbine is of the impulse type, the casing being lined with refractory material. Gasoline is used as fuel, and is fed under pressure through an expanding nozzle, being ignited electrically and generating a temperature of combustion of over 3,000° F. The blades were cooled to a certain extent, while rotating by low-pressure steam admitted into the casing.

THE refinery at Argo, which was burnt on September 15, is not to be rebuilt. The Boston & Colorado Smelting Co., which owns this smelter, close to Denver, will send the gold bullion to the Denver Mint and the silver to Omaha. The refining process used at this pioneer establishment has proved expensive, owing to the special skill required. The method has been kept secret for thirty years. Smelting of copper ores will continue as heretofore. Harold V. Pearce is manager, having succeeded his father, Richard Pearce, several years ago.

REFRACTORY MATERIALS should be tested for infusibility and insolubility in the presence of molten material to which they may be exposed. The former test is made by heating strongly small sharp-edged objects fashioned from the clay. To test this power of resistance to corrosion, the clay should be dried and one-third baked and ground to a coarse powder. This is mixed with the raw clay and made up into crucibles and burnt. One of the following charges may then be fused in the crucibles on a firetile in a hot muffle and the corrosive action determined: Granulated copper 30, borax 1; litharge 40; silica 12, sodium carbonate 2, hematite 5 grams.

SHAFT-SINKING.—The cost of sinking the shaft of the Victoria Quartz mine, at Bendigo, the deepest gold mine in the world, will interest our readers. The shaft is down 4,300 ft., the sump being 46 ft. below the bottom plat at 4,254 ft. A cross-cut is now being driven east at 4,125 ft. to pick up the reef which was discovered in the centre-country winze below 3,824 ft. Subsequently, the cross-cut at 4,254 ft. will be driven. The manager states that owing to the system of ventilation the air at the 4,024-ft. plat and between 4,154 and 4,254 ft., is good, and consequently some records have been made in the matter of sinking. The wages account for the period while sinking has been in progress amounted to £874, while material cost £749, making a total of £1,624. The cost per foot of sinking, therefore, averaged £5 16s., while the two plats involved an expenditure of £162. The principal items of expenditure were wages and firewood. The amount disbursed in wages was £787, or £3 1s. 8d. per ft., and £87 for the men engaged in cutting the plats. The firewood consumed in connection with the shaft-sinking was calculated at £315, or £1 5s. per ft., and for the plats £35. The timber for the shaft cost 13s. 3d. per ft. The cost of the explosive used was 7s. 3d. per ft. in sinking, and £10 in the two plats.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Cyanidation vs. Chlorination.

The Editor:

Sir—In your issue of September 8, after giving the output of the ore treated by the Cripple Creek mills, the remark is made that "it being evident that cyanidation is gaining as against chlorination in the treatment of low-grade ores."

Two years ago (in *The Engineering and Mining Journal*) I ventured to predict that chlorination would prevail, in the treatment of Cripple Creek ores, as against cyanidation. Comparing my figures given at that time with those in your issue of September 8, it would appear that the advantage is entirely with the chlorination process.

TREATMENT OF CRIPPLE CREEK ORES, MONTHLY.

	—Smelting—		—Chlorination—		—Cyanidation—	
	Tons.	Value.	Tons.	Value.	Tons.	Value.
1904.....	11,000	\$660,000	40,000	\$1,049,000	9,000	\$192,000
1906.....	7,500	600,000	35,000	966,400	4,700	21,000

This comparison speaks for itself. While the chlorination mills have practically held to their own record, they have gained relatively, both over the cyanide mills and smelters. Since two years ago, the tonnage treated by the cyanide mills has fallen 50% and the value of the ore treated now is only 10% of what it was then. It is true that several other cyanide mills will soon go into commission, which will augment the amount and value of the ore treated by cyanide, but it is equally true that two years ago a greater number, and larger, cyanide mills were going into commission than there are now.

There are at present, in the Cripple Creek district, ten cyanide plants having a total aggregate capacity of 1,600 tons per day. Only three of these mills are now operating, with a daily aggregate of 160 tons. Most of these mills were built, or at least first started operation, less than two years ago. None of the cyanide mills are now operating on a custom (that is, a competitive) basis.

There is no essential information, in cyanidation, available today which was not known two years ago. Almost every variation of the process has been tried at Cripple Creek, so that there is no particular reason for believing that the cyanide mills will meet with any better success in the future than they have in the past.

It is generally conceded that in the treatment of telluride ore by cyanidation, roasting, while not essential, is nevertheless desirable. The only plants at Cripple Creek which have met with success are those in which roasting formed an integral part of the process. Since roasting and percolation, in cyanidation, has not been able to compete with chlorination, it remains to be seen whether roasting, sliming, agitation, and filtering (a procedure similar to the Mariner process in Australia) will meet with better results. When, however, roasting forms a part of the treatment in both processes, it seems incomprehensible that the ore can be slimed, cyanided by agitation, and filtered as cheaply as it can be treated by simple chlorination when the ore is crushed to 12 or 16 mesh, especially in view of the fact that the application of electrolytic chlorine is no longer experimental, and can be produced under Cripple Creek conditions for less than four cents per pound. Even this expense will ultimately be eliminated when the caustic soda, which is a necessary by-product in the generation of chlorine by electrolysis, is converted into marketable shape, and made to pay for the chlorine used in treating the ore.

Who Is a Mining Engineer?

The Editor:

Sir—I have followed, with interest, the discussion in these columns recently, as to what constitutes a mining engineer, and as I had rather a sharp correspondence a few years ago, wherein I pointed out to a person who used the letters M. E. after his name, on the strength of a correspondence course in mining, the impropriety of such use, I shall be pardoned, perhaps, if I express my views in the present instance.

It seems probable that this discussion would not have arisen had there been a good generic name, besides the name which is commonly used to designate the holder of the college degree of Engineer of Mines, for that group of professional men who concern themselves with mines and mining. Among the other professions there is not such ambiguous uncertainty as to who is who—and how; and the reason is that definite tests have been provided which must be successfully met before the candidate can take the title of his profession. Thus: No man can call himself a lawyer or practice law until he has passed the Bar examinations; neither can a man take the title of clergyman until he has been ordained; nor can anyone call himself a physician or surgeon until he has been graduated from a medical school.

In mining, however, there are men who have obtained their knowledge and received their training in many different ways: There are good mine managers who have never seen the inside of a college, or perhaps have never even attended a high school, yet who have, by sheer ability and force of character, acquired the requisites that go to make a good mine administrator. Again there are those who have taken college courses in other things, the Arts even, who have afterward gone into mining, and have made good. Also there are the men who have taken courses in mining at colleges which confer the Bachelor of Arts or Bachelor of Science degrees alike on all of their graduates, no matter how they have specialized. Finally there are those who have graduated from a college or school of mines which gives the degree of Engineer of Mines to its graduates in mining. In all of these classes there are many good engineers, who have a right to professional consideration in any classification of mining engineers as a body, that might be made. As the colleges are turning out an increasing number of men holding the degree of Engineer of Mines, or Mining Engineer, as the case may be, and as these men, while indubitably having a right to the use of their degree, are still, through lack of experience, unready for administrative positions, it seems to me that a just distinction can be made between them and the men who have "arrived"—in this way: Let the raw graduate, until he gets to be a mine manager or superintendent, and while he is still assaying or surveying, or pushing an ore-car, use his title to express the fact that he is as yet merely a degree holder. Thus: John Jones, E. M., or John Jones, Engineer of Mines, Columbia, 1906, would express that idea. After he has been out of college a few years and is in responsible charge of a mining property, let him then, and not before, write his name John Jones, Mining Engineer. If he wishes to express both facts he could write his name John Jones, Mining Engineer, E. M., Columbia School of Mines, 1906.

Let the title, then, of Mining Engineer, thus written out in full, be used by those only who have attained to the responsible, technical administration of mining properties, whether they hold college degrees or not. Let the college men use only their college degrees until they can use the higher term, and let all others who will, call themselves mining experts.

Among the mining men who have specialized along

one line, I think that Mr. J. H. Curle has happily adopted a title both descriptive and good, in that of Mine Valuer, and it is hereby commended to those mining men who devote themselves exclusively to examination work.

Should the matter be of any interest, I can say that I am a graduate in mining from a college of recognized standing, and hold the degree of Bachelor of Arts. Since my graduation I have had the responsible technical administration of mining properties, and consequently sign myself simply,

A MINING ENGINEER.

Telluride, Colorado, September 19.

Who Is a Mining Engineer?

The Editor:

Sir—As there are no statutes defining the status of a mining engineer, the public should have some idea of what the term means. The definition I propose will no doubt be sneered at by a class of practical men who imagine an engineering education is a *sine qua non* of everything impracticable, and in this they display as much ignorance as the young graduate does when "he thinks he knows it all." A 'mining engineer' is one who takes a diploma from an institution making a specialty of mine engineering. Any other person, no matter how well qualified, is not a mining engineer, or the designation loses all significance. He may be a 'mining expert' or anything else, but not a 'mining engineer.'

ALGERNON DEL MAR.

Oroville, Cal., September 15.

De-Suplhurization.

The Editor:

Sir—In 'Pyrite Smelting,' edited by T. A. Rickard, one of the ten questions propounded by him was: What is the degree of desulphurization attainable? it being understood that the treatment of sulphide ore was meant. The question as to how much of its contained sulphur could be burned off, when re-smelting matte for concentration, was not referred to, and I would therefore propose the question: What degree of desulphurization is attainable in the concentration of matte? This question is the more important, since in the older practice of matte-smelting with the use of 10 to 14% coke, it was understood that raw matte, put through the furnace, issued thence unchanged. Peters says that "in the powerful reducing atmosphere of the blast-furnace, the sulphurous acid, even when once formed, comes in contact with an overwhelming proportion of CO, which in burning to CO₂, decomposes the SO₂ reducing it to sulphur, in which condition it unites with iron or copper and enters the matte, thus increasing the amount of this product while it robs the slag of its most valuable constituent."

In 'Pyrite Smelting,' W. H. Freeland, in the chapter entitled 'Raw Sulphide Smelting at Ducktown (Tenn.),' makes a concentration of his matte 2.5 into one and adds: "This by no means represents the limits attainable. Contrary to the experience of many, the re-concentration of the first matte presents no difficulties at Ducktown. There is no limit within the range of matte to the second operation. A 6% matte may be brought up to a 50% matte quite as successfully as any higher grade initial matte, nor is this based upon odd or occasional samples, but upon more than one car-load of matte so made." The just-named concentration of 2.5 into one was effected in presence of 5.6% coke, so we can only assume that an overwhelming amount of air was present—enough to produce an oxidizing effect. And this appears to be the secret of success in such concentration.

J. Parke Channing, on page 260 of 'Pyrite Smelting,' gives the result of two runs of low-grade matte, giving concentrations of 4.8 and 4.4 into one, respectively, with the use in the first case of 4.5% coke and in the second of 3.5 per cent.

Whether these results can be got elsewhere is a question. In the Salt Lake valley, for example, they attain a concentration of 3 into 2 and of 2 into 1, at the most.

L. S. AUSTIN.

Berkeley, Cal., August 18, 1906.

Machinery Merchants and Metallurgists.

The Editor:

Sir—We are constantly hearing of industrial plants that have lamentably failed. Among all the pathetic monuments of incompetency and misjudgment, the abandoned or dismantled ore-mill is perhaps the most common; and nothing, in later years, has brought so much discredit upon the profession of the metallurgist. The chief causes of these failures are the lack of ore supply and mistakes in installation for which the amateur metallurgist is responsible. But there is another cause, not so obvious and generally recognized, and that is the gradual intrusion of mining-machinery houses into the special field of the metallurgical engineer. The sophisticated mine-owner is not likely to intrust his milling problems to machinery firms; but there is a numerous class comprising prospectors and promoters in process of transformation into mine-owners, engineers, and 'experts,' who instinctively flock to the machinery houses for direction and advice. A common lure is the ore-testing plant that some of these firms operate as an annex to their machinery business, thus assuming the ability and the right to give professional advice. To the novice incapable of judging the merits of a machine or a process, a little glib talk, and a superficial exposition of what a machine will do, carry instant conviction. It is inconceivable that mine-owners and companies will plunge headlong into fatal mistakes by ignoring the one supreme truism so patent to the engineer—that the man who has a machine to sell is the last one to appeal to for advice! The business of such a man is to sell his machine, and the business of machinery houses is to sell the machinery of which they are the manufacturers or agents. The result often is that the plant installed by a machinery house is either a failure or a monstrosity; and the machinery merchant, with the subtlety of his kind, somehow contrives to elude the responsibility, and goes on his way rejoicing. The hesitation on the part of companies or individuals to employ only disinterested and skilled professional service in the examination of the properties and in the selection of their milling processes, is a subject which is being so emphatically rehearsed in current mining literature, that it seems almost unnecessary to touch upon it again. The incredible thing about such advice is that it should be necessary at this late day to offer it at all. And yet the penalty of disregarding it is still glaringly manifest in whichever direction we turn, and the examples of it are constantly multiplying.

W. H. L.

New York, October 2.

At the Victoria Quartz Mine, Bendigo, the sinking of the shaft has been completed to the great depth of 4,300 ft., and the mining inspector has visited the mine and taken observations. He found that at the plat at 4,020 ft., the temperature was only 76° F., while at the same spot there were 10,000 cu. ft. of air per min. passing through the cross-cut. At the bottom of the shaft the temperature was 86°, and the water running out of the ground registered 114 degrees. There was also a slight circulation of air at the bottom of the shaft.

Three Weeks in Mexico.---VIII.

Concluding Notes on El Oro.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

Dos Estrellas, or the Two Stars, is one of the three great mines of El Oro; it is interesting not only because of its generous production but also by reason of the romance of its discovery. J. G. Fournier, its present chief owner, is a Frenchman of education who prospected the region roundabout with much persistence. He found 'float' (detached lode-stuff) where the shale is exposed below the andesite cap and he found similar indications also in the *barranca* (or gulch) at the foot of the mountain. Subsequently, he started to work at the creek level and ran a long adit to intercept the vein that he believed to be there. At a distance within the mountain of about 2,000 ft. he found it, and no mistake. It was the great Dos

wood, or in excavating for foundations—is paid 50 centavos per day, but it is becoming difficult to get men for such pay. In a new mining camp or on the farm, the day laborer is paid only 25 centavos, while in the north, near the border, he gets three pesos. This is owing to the proximity of the American labor supply and the competition between the mining companies, the wages tending to equalize despite the international boundary, because both the northern workmen and the Mexicans go across that line, to and fro.

As much as possible of the work underground is done on contract; even the trammers and skipmen are employed on this system, prices being set so that the miners earn from 1 to 1.25 pesos per shift. In measuring ground under contract, the unit is a width of two sets (3.4 metres) of timbers, and the pay is so much per metre long for the full height of a set (two metres). Mine contracts are made with each gang of six men or more, the agreement being arranged with the two leaders (one to watch

A Group of Mexicans at Work.

Estrellas lode, which is divided into two veins, one 3 to 5 ft. thick, with rich bodies of ore in it, and beyond it another vein 40 ft. thick of 12 dwt. gold ore; the latter is oxidized, but the small vein is not, except in patches. This resembles the conditions in the Esperanza, where the new West vein is smaller, richer, and unoxidized, while the old San Rafael is wide, poor, and thoroughly oxidized. Fournier was long ago regarded as a crazy man, as has been the case in several similar instances of persistent prospecting. Thomas Kruse who discovered the Drum-lummon lode, at Marysville, in Montana, worked all alone. He started to sink a winze and gave it up; he then commenced to dig a 'tunnel' for a supposedly unknown lode. When he cut a big width of ore, it was considered, by the ignorant, as fool luck. But it was nothing of the kind; old Tommy Kruse had found an outcrop and he knew that he alone could not sink a shaft, but he could drive a drift into the hill without assistance and without the risk of sharing his discovery. He persisted in his solitary labors, and won a fortune.

The ordinary unskilled laborer—such as is required for carrying material, for unloading, for stacking cord

the other); and these hire any additional labor such as is needed for removing rock or tramping. Contracts are measured weekly, on Saturday night. Wages also are paid weekly, the surface laborers on Saturday night and the miners on Sunday morning; this frequency of payment being due to the fact that the *peones* have not enough money to carry them longer than seven days. On Sundays the market is crowded with vendors of corn (maize, from which *tortillas* are made), beans (the *frijoles*), vegetables and fruit. The Mexicans lay in a week's supply; any money remaining is spent on *pulque*. On Monday they are in a demoralized state. Owing to these customs, the laborers lose two days per week regularly, besides an extra feast day (*fiesta*) each month. But annoying as these conditions are to an energetic management, they are better than they used to be. Even on local holidays, the *peones* formerly took three days for their celebration, while now one day ordinarily will suffice. But there are still seven or eight *fiestas* in the year when no pretense of working is made, and operations underground cease. Of course these national characteristics of the Mexican do not affect—at least directly—the American workmen; they are paid

monthly, and appear to be not only sober in their habits, but also unusually efficient.

Mexicans take kindly to mechanical labor, such as that of the machine shop or carpentering. The average native carpenter, who gets from 2 to 4 pesos per day, is as good as the white men of his trade that drift into the country from the north. Timbermen are fairly satis-

have any of that body swing, when the hand slips over the long handle of the hammer; instead of this, they have a tight grip and strike short blows over the shoulder; they will insist in shortening the hammer-handles; nor do they use the pick where obviously it would bring down loose ground, but they worry the rock with short hammer-blows delivered with woodpecker persistence. Their

hammer-heads get into woeful condition and their picks are rarely such as a white man would care to own; in general, they appear to take poor care of their tools. Owing to their inability to swing the hammer freely over the shoulder, they cannot drill an upper and therefore they are not much good in a raise; but they are 'daisies' in a winze. At the south end of El Oro mine, I saw some Mexicans sinking a winze below the 286-ft. level and they were down over 80 ft. on a dip of 65°. All the rock they broke was being carried in sacks on their back, from the bottom of the winze to the level, and they were being

Pay-day at the Casa Blanca.

factory also; they receive two pesos per shift. As a rule, the Mexican is clever with his fingers, as is illustrated in the shaping of statuettes, and in weaving. Guadalajara is famous for carved images and Cuernavaca for the manner in which its people mold clay into statuettes and flower pots.

The assay crucibles used in El Oro mill are made locally; so also the muffles. The crucibles, sizes F and G, holding 2 A. T. assays, cost only two centavos apiece and give excellent service.

In different parts of Mexico the skill of the miners will vary; at El Oro it is less than at Pachuca. The

cost per ton of ore is not much cheaper than if done by skilled white miners. Mexicans are not miners by instinct; as long as they can maul at a face and detach chips of rock, they will hammer it, instead of picking it loose or putting in a shot. They are wretched hammer-men; a Cornishman who watched them would be inclined to say that it was a "caution," and the American miner would exclaim that it was a "fright." They do not appear to

paid 15 to 20 pesos per metre for a winze 3 ft. wide by 6 ft. long. In the Mexico mine, winzes 5 by 6 ft. cost 25 to 30 pesos per metre. The shift-bosses in the Es-

Drilling in a Rich Stope.

peranza mine are mostly Italians (Piedmontese), they are among the best miners in the world and learn Spanish readily; in a month they acquire a working knowledge of the language and they seem to know how to manage the *peones*. Most of the Piedmontese in Esperanza come from Bisbee, simply because the foreman worked there at one time.

Boys are employed underground for minor tasks, such

as doing errands, carrying water, and cleaning tracks. They are only 8 to 10 years of age. On the whole, the full-grown men are not well built, they have the physique of a big boy rather than that of a mature man; their strength is all in the back, the muscles of which have been developed by generations of burden-carrying. They can transport enormous loads on their back, but are incapable of carrying any weight in their hands.

At the Esperanza there are 3,952 men employed; scarcely three per cent are whites. For some tasks it is necessary to use four or five Mexicans to accomplish what one white man could do, but on other jobs the Mexican will do what the white man cannot do at all, especially as regards carrying loads. The Mexican will often serve where a mechanical device would cost more.

They work naked save for a loin cloth and sandals (*guaraches*), for the air underground is very warm. On the second level of the Mexico mine it was 85°; in the shaft (owing to steam pipes) fully 100° F. In the cross-cut from the 286-ft. level going west from the Somera shaft the temperature was 95°, and in the cross-cut, at 1,086 ft., it was up to 105° by reason of poor ventilation and escaping steam. The general temperature in the workings is 60° to 70°. The heat is due largely to the action of water on the lime in the shale—slaking it—and it may be due also to the crushing of the shale, which is often seen to press heavily on the timbers.

The authorities keep a close grip on the native population. Strikes are rare. They occur occasionally in the cyanide plant, where the men that tram the sand are inclined to think that they do too much. El Oro has never had a big strike. Should there be any disorder or insubordination requiring serious action, the *Jefe Politico* (sheriff) is asked to call out his *rurales* (police) and these arrange affairs by capturing the ringleaders, after which the crowd scatters at once. The *peon* is an inveterate thief; the mill-hands steal ore and the precipitate in the zinc-room whenever possible. When caught in the act, the culprit is turned over to the *Jefe Politico* and in short order the latter sentences him to serve in the army. He is made a compulsory soldier and may be drafted to the hot country of the Yucatan peninsula, which is equivalent to exile. To put the *peon* in prison means nothing to him; he has a quiet time, his friends bring him food, he is required to clean the streets or to do similar municipal work; it is no punishment to him; but to be placed in the army means wailing and the gnashing of teeth among his friends.

Even the operation of a cyanide plant may yield humorous incidents. A note-book belonging to one of the former assistants was found; it recorded the work done on the night shift in the precipitation room. The particular fragment rescued from fire contained instructions how to pump out the precipitate-sump and to make cake in the press. The operator, a new hand, had recorded that at a certain hour "pump laboring—opened press to see why—found press choked with greasy black substance—removed same—pump worked perfectly." He threw the precipitate into the old (empty) cyanide boxes, where it was found next day; no damage was done. Another story is that of visitors being shown over the new mill by a guide from the village of El Oro; he pointed to the tailing wheel, which is 40 ft. 8 in. high, and said that it was the wheel that operated the mill, the conveyors, and everything in sight. This wheel is run by wire ropes; there are two that transmit movement to the wheel itself, there are four that drive the first line of agitator-shafts, and there are two more that go to the pumps; all of them happen to be close together and doubtless the number of ropes created the idea that the wheel was responsible for a great multiplicity of duties.

The only salvation for land titles is due to the regula-

tion which compels monuments to be visible from one to the other. By law also it is specified that the monuments must be permanent stone structures; otherwise there would be hopeless confusion, for the records in the mineral-land offices would be unintelligible, because there is no general map and the boundaries of claims are not referred to any fixed point or landmark.

The boundaries between the Esperanza and El Oro mines are marked by posts of masonry plastered with white mortar; they are set at each corner of a claim and where the lines are long they are placed at such intervals as to be within sight from one to the other. The local inhabitants, some of whom thought they had squatter's rights to the ground, started to demolish these monuments until the company's surveyor marked, with black paint, a cross on each one; since then they have been reverently left untouched. Similar superstitious feeling is seen in other observances. Wherever a man dies—whether naturally or not—a cross is set up, even underground in the mine; and each man who passes by picks up a stone, which is supposed to represent a paper, the equivalent of a prayer, and drops it at the place so designated. On the day of the Holy Cross every cross in the country is decorated with flowers, even artificial ones if others are not procurable. By the heaping of stones at such spots, a cairn is eventually formed, serving as a landmark. At the place where a priest was killed, near the Somera shaft, there is an enormous pile of stones.

In the course of a ride on horseback over the surrounding district, on a Sunday, one can observe something of the life of the people. There is a notable absence of vehicular traffic; there are no ruts in the roads, which practically are causeways, worn smooth by the sandals and bare feet of the peasants; the paths look as if all the 'weary Willies' in the world had passed that way. The beauty of the scenery and the picturesque coloring of the people is spoilt by the evil smells due to the filthy habits of the *peones*. At the close of day, when the tropic darkness comes swiftly and the air is suddenly cooled, the Mexicans stalk about silently muffled in their *serapes* and with covered mouth, in order not to inhale the air. It is a characteristic of the people that they fear the cold air, largely because they are so poorly nourished as to be easily subject to pneumonia. With their wide-brimmed conical hats, the dirty red blanket or the striped *serape* thrown over the shoulder, with thin shank and stealthy gait, they stalk about in the gloaming through the narrow street like the brigands of an *opera bouffe*. There is none of the breezy swing or the cheerful salutation of the Anglo-Saxon; nor is this a matter for wonder when one gets to know the miserable life, the petty tyranny, and the scant food that is their lot. Cleanliness, good food, and freedom of opportunity make people more cheerful even in a climate less sunny than Mexico.

Nothing that I saw in Mexico seemed so pathetic as the conventional acceptance of class distinctions, especially among the women, the sex usually most eager to ape the dress and habits of those who happen to be more favorably placed than themselves. The lowest class wears blue and brown shawls (*rebosos*), the middle class is distinguished by black *rebosos* and the upper class sports the more dainty *mantilla* or mantle of lace.

The most vivid impression that I took away from El Oro was that of a Mexican boy controlling the operation of a sand distributor through a variable-speed motor. The boy's pay was 75 centavos, or 37c. per day, and he had charge of two Blaisdell excavators and the distributor referred to. It was a picture of mechanical ingenuity overcoming a poor labor supply, for it was not the skill of the boy so much as the perfection of the machine that rendered such economy of operation possible.

About Mineral Belts.

Written for the MINING AND SCIENTIFIC PRESS
By THEO. F. VAN WAGENEN.

Some ten years ago, and in the pages of the *School of Mines Quarterly* (Columbia University), I called attention to the fact that all the metal-producing centres of the western part of the United States (excepting placer districts), from the Plains to the Pacific and from the Canadian to the Mexican lines, lay along about a dozen narrow belts of country, all parallel to each other, with a general direction northeast and southwest, and with widths ranging from 10 to 20 miles. Accompanying the article was a map showing these belts, a photographic reduction from one six feet square. The former proved to be upon too small a scale to exhibit details properly, and the latter was shortly thereafter accidentally destroyed. Since then I have never had the leisure to reproduce it.

In this large chart the outlines of the several belts that passed through the State of Nevada gave much trouble, and were not satisfactorily defined. There was a tendency, as I then had them, to unite with each other quite improperly, or to merge into one very broad belt, to the practical destruction of the belt theory in that locality. I have since ascertained that this was due to errors and defects in the Nevada map, a large number of the mining centres having been incorrectly marked. This condition of inaccuracy is true to a greater or less extent of the maps of all the Western States. But having corrected many of the worst errors, I am thoroughly satisfied that, if an accurate map were made of the West, all primary metal producing regions would be found disposed along a dozen well defined lines, stretching like gigantic lodes diagonally across the country from the Plains and the Canadian border to the Pacific and the Mexican line.

During the last four years opportunity has been afforded to ascertain whether similar physical conditions existed in other parts of the world. Three years have been spent in South Africa, and one in Mexico, and in this period nearly all the known mineral districts of both have been visited. About the first thing I noted was that the maps, like those at home, were inaccurate as regards the position of most of the small towns. This was to be expected, as in neither country have the governmental surveys been carried forward sufficiently to afford a fair basis for cartographical work. Nevertheless, in both the position of the principal mineral centres have been well ascertained, and when these were marked on the map, as red dots, and the little ones put in as fast as their true position was known, it became evident—as might have been expected—that nature had worked in these parts of the world in the same way as in the United States. In Mexico, from the international boundary down to the Isthmus of Tehuantepec, there are at least 16 well defined lodes or mineral belts crossing the country from the northeast to the southwest, all parallel to each other, and none more than 25 miles wide. Between them, just as with us, are strips from 100 to 125 miles wide, where no mining districts exist, and no metals have been found. As Mexico has been in the hands of the prospector for nearly 500 years, this is a most significant fact. In South Africa, four belts are easily traceable, each presenting the same characteristics as those on the American continent, and if the modern prospector is ever allowed to work in that region, no doubt he will unearth many more of them.

It is likely that the conditions in other parts of the world are the same as in the North American continent and South Africa, and if so, there is a meaning to it all, that, if understood, is liable to be not only of scientific interest,

but of commercial importance. In my first article on the subject, working with defective maps, and confining observations wholly to the Western States, it seemed as if these belts showed a tendency to conform, in the matter of direction, to the lines of magnetic variation. But later and more detailed examination dispelled that idea. As far as I have now re-constructed the original chart, these belts show a uniform course of almost exactly northeast and southwest, just as is the case in South Africa and Mexico.

The reader who is interested in the subject will please remember that, while in every case within the borders of the United States, it is possible to trace a belt from the Plains or the Canadian border, to the Pacific or the Mexican border, according to the position it occupies on the map (as, for instance, the long one beginning in the north in the Black Hills of South Dakota and passing into the ocean a little north of San Diego), yet there are parts of each belt where the line passes out of mountain regions into and through extensive agricultural areas, or areas of very modern rock formation, and such parts generally lack mining districts. Nevertheless, I think it will be proved in time that the belt or lode persists underneath both. In all cases it appears beyond in good line, and there are several instances where, within such non-mining regions there are isolated upheavals of the underlying deeper formations. In those that are on the proper line, deposits of the metals have been found, while none occur in those off the line.

Taking the example of the Black Hills-San Diego belt or lode, if its line is prolonged northeastward it leads directly to known mineral districts in Canada. The course of one of the South African belts disappearing under the Indian Ocean, passes directly through the Mysore goldfields of southern India. Coming nearer home, the principal New Mexican belt, which is clearly defined, can be followed through an almost continuous line of mining camps in Chihuahua and Sonora to the Gulf of California, and then appears again in full strength in the narrow peninsula of Lower California. To the northward its line, dipping under the prairies of Kansas, Nebraska, South Dakota, and Minnesota, leads directly to the Rat Portage mining district in southern Manitoba. In other words, these belts seem to be continuous lines of metallic mineralization, whose course it may be possible to trace clear around the globe.

Some conclusions of interest and value can probably be drawn from the statements above given, and after that is done, if one wishes to speculate, there is ample scope for the imagination. The facts seem to be about as follows:

1. Primary deposits of the metals in the crust of the earth occur along certain well defined lines, which (diagonally or spirally) encircle the globe in a general northeast and southwest direction, are from 5 to 20 miles wide, and have all the general characteristics of gigantic lodes or veins, being in some places well laden with ore (*en bonanza*), and in others nearly barren (*en borrasca*). The former are the rich and prosperous and payable mining districts along their line, and the latter are the non-payable areas, where only traces of the metals are found. Intermediate are all the intervening degrees of mineral segregation and concentration, which are payable or not, according to the economic conditions prevailing.

2. Between these great belts or lodes are areas averaging 100 miles or more in width, which are entirely devoid of primary metallic mineralization.

As conclusions from these, it would seem that metals do not occur in the earth's crust as the result of the existence or juxta-position of certain rocks, or classes of dikes, or plutonic intrusions, that have heretofore been considered favorable for their segregation and concentration.

Nor has the trend or rock-structure of mountain chains much, if anything, to do with the determination of their locality, for these belts cross the lines of mountains at all imaginable angles. At the intersecting places the latter are mineralized. Elsewhere they are barren. As these mineral belts are invariably—as far as my observation goes—a little bent out of their normal direction in passing through a mountain range, it would seem as if the systematic mineralization of the crust of the globe must have occurred before the era of mountain building. Finally, there are certain regions where the prospector will be wasting his time in searching for ore, and others that appear—so far as surface indications go—to be of no account from a mining standpoint, but which are really first-class prospecting areas.

Some effort should be made by the Geographical Survey to indicate on maps the approximate boundaries (in the United States) of these two classes of territory, for the guidance of the miner. It would have the effect of doing away with some of the hazard and uncertainty of the prospecting and mining occupations.

Now as to speculation. If the globe is encircled with a continuous spiral of metallic mineralization, or a series of parallel circles of the same, like the soft iron core of the telegrapher's magnet, this metallic wrapping—so to speak—may be the cause of its magnetism and polarity. Or, to look at it in another way, these metallic channels should be the lines along which travel electrical currents of more than normal strength, and they may have had much to do with the segregation of the minerals into bonanzas and ore-shoots. If so, the electrical tension in deep mines is worth investigation. If electrical currents determine the situation and size of orebodies, and we can gain a knowledge of the way they operate, that knowledge promises to be of assistance in ascertaining the position of bonanzas yet undiscovered.

LARGE CHECKS.—A boast came out of the West last week. "What is said to be the largest check issued in ten years," it read, "was drawn by Banker Hellman at San Francisco to close the Spring Valley water deal. The check was for \$13,792,000."

The California correspondent ought at least to have been familiar with the \$40,000,000 paid by the Government to J. P. Morgan & Co. in the matter of the Panama Canal purchase. This sum, however, was not, strictly speaking, in the form of a bank check. It was transferred from Washington by Treasury warrant ordering the Assistant Treasurer at New York to pay \$40,000,000 to the order of J. P. Morgan & Co. The New York Clearing House, however, has record of enough big checks drawn in recent years to put the California record in the shade without falling back on this Government payment. The organization of the Steel Trust in 1901 furnished the necessity for the largest check on record, which was drawn by J. P. Morgan & Co. in payment for the Carnegie steel plant. The amount was \$23,127,016.67, and the check was drawn on the First National Bank, with which it was deposited Feb. 15, 1901. It did not pass through the Clearing House. Next in order stand two checks, one for \$17,000,000 and the other for \$17,500,000, both of which were drawn by Kuhn, Loeb & Co. on May 25, 1900, to the order of Hugh J. Grant, receiver, in payment for the Third Avenue Railroad when that property was acquired by the Metropolitan Street Railway Co. The first of these checks was drawn on the National Bank of Commerce and the other on the National City Bank. They were both deposited with the Morton Trust Co., which put them through the Clearing House. Still another check which the New York Clearing House officers thought large enough to make a mem-

orandum of was one for \$14,890,697.40, which Kuhn, Loeb & Co. drew in payment of 50% of the purchase money for the controlling interest in the Southern Pacific acquired by the Union Pacific in 1901. This check came into the Clearing House March 5, 1901, in the exchanges of the Bank of the Manhattan Co., which clears for the United States Trust Co., where the check had been deposited. It was drawn on the Mercantile Trust Co. and was paid by the Fourth National Bank, which was the redemption agent of the Mercantile Trust Company.—*Boston Financial Journal*.

THE MARINER'S COMPASS.—Much interest must forever attach to the discovery of this instrument, and yet there are few subjects concerning which less is known. For a period the honor of the invention was ascribed to Gioia, a pilot born at Pasitano, a small village situated near Amalfi, about the end of the thirteenth century. His claims, however, have been disputed. Much learning and labor have been bestowed upon the subject of the discovery. It has been maintained by one class that even the Phœnicians were the inventors; by another that the Greeks and Romans had a knowledge of it. Such notions, however, have been completely refuted. One passage, nevertheless, of a remarkable character occurs in the work of Cardinal de Vitty, Bishop of Ptolemais, in Syria. He went to Palestine during the fourth crusade, about the year 1204; he returned afterward to Europe, and subsequently went back to the Holy Land, where he wrote his work entitled 'Historia Orientalis,' as nearly as can be determined, between the years 1215 and 1220. In chapter XCI of that work he has this singular passage: 'The iron needle, after contact with the loadstone, constantly turns to the north star, which, as the axis of the firmament, remains immovable, while the others revolve; and hence it is essentially necessary to those navigating on the ocean.' These words are as explicit as they are extraordinary; they state a fact and announce a use. The thing, therefore, which essentially constitutes the compass must have been known long before the birth of Gioia. In addition to this fact, there is another equally fatal to his claims as the original discoverer. It is now settled beyond a doubt that the Chinese were acquainted with the compass long before the Europeans. It is certain that there are allusions to the magnetic needle in the traditional period of Chinese history, about 2,600 years before Christ; and a still more credible account of it is found in the reign of Chingwang, of the Chow dynasty, before Christ 1114. All this, however, may be granted, without in the least impairing the just claims of Gioia to the gratitude of mankind. The truth appears to be that the position of Gioia in relation to the compass was precisely that of Watt in relation to the steam engine—the element existed, he augmented its utility. The compass used by the mariners in the Mediterranean during the twelfth and thirteenth centuries was a very uncertain and unsatisfactory apparatus. It consisted only of a magnetic needle floating in a vase or basin by means of two straws on a bit of cork supporting it on the surface of the water. The compass used by the Arabians in the thirteenth century was an instrument of exactly the same description. Now the inconvenience and inefficiency of such an apparatus are obvious; the agitation of the ocean, and the tossing of the vessel, might render it useless in a moment. But Gioia placed the magnetized needle on a pivot, which permits it to turn to all sides with facility. Afterward it was attached to a card, divided into thirty-two points, called Rose de Vents, and then the box containing it was suspended in such a manner that, however the vessel might be tossed, it would always remain horizontal.—Quoted by the *Electrical Engineer* from an old magazine.

The Pot-Roasting of Ore.

Written for the MINING AND SCIENTIFIC PRESS
By LEONARD S. AUSTIN.

This method of preliminary treatment is essentially a roasting process, performed in large pots or semicircular kettles capable of holding ten tons of ore. The method has also been called the Huntington-Heberlein (H & H) process, but in that process, as patented, ore containing 30% and upward of galena was blown with the addition of limestone in quantity sufficient to prevent premature agglomeration, but rather a sintering, which would make the product suitable for the following operations of smelting. As the process was developed in the United States it was soon found that ore of a much lower tenor in lead might be profitably treated and in which no limestone was needed.

The plant consists of a building having a central nave or bay which contains one or more rows of pots all commanded by a traveling crane. On one or both sides of this nave are to be found the aisles or side bays where are situated Godfrey single revolving hearths roasting furnaces having a capacity of 20 to 25 tons daily and where the ore is roasted without the use of exterior fuel to a contents of 12 to 14% sulphur. An objection has been made to this type of roaster as now designed that lubrication is unsatisfactory owing to the high temperature at the bearings below the hearth. The central bay is extended so that the roasted ore may be dumped beyond the space allotted to the pots.

An ore mixture for roasting is now commonly made up containing no more than 7 to 10% lead, 30% silica, and 20 to 25% sulphur, silicious ore being added to mixed sulphide in such amount as to secure these proportions. The addition of this dry ore has the effect of making the mixture more infusible, and of preventing the particles from running together. The ore, even when agglomerated, still retains its open texture and is capable of penetration by reducing gases in the blast furnace.

Fig. 1 represents a pot *A* of eight and one-half feet diameter placed in a pit *B* and connected at the bottom by a tuyere to an air-main by which air may be introduced to the pot under pressure. To carry off the gases which are developed a hood or cover *C* is lowered upon the pot when it has been charged, this being connected by an adjustable branch pipe *d* to the flue *e*. The pot has a cast-iron false bottom *f* perforated with 0.375-in. holes through which the blast enters and a baffle-plate *g* which serves better to distribute the air-blast.

In operation, a barrow-load of ashes is sprinkled upon the false bottom, forming a thin layer to prevent the sticking of the charge. In certain practice, in place of the ashes, some limy lead-free ore has also been successfully used. The ore thus in contact with the false bottom is but little affected by the heat, so that the limestone is not burned to quick-lime. Upon this layer is dumped a quantity of upward of a ton of hot roasted ore, which serves as a means of starting fire to the ore added upon it.

On the hot ore is dumped, in some cases, no more than

two tons of the regular charge or mixture, which contains five per cent or more of water, and which has been roasted down to 12 to 14% in a Godfrey roaster, a single revolving-hearth furnace of 20 ft. diam. When the two tons have been well started the rest is then added. An important requirement seems to be that the ore thus to be treated shall be moist. It may be considered that under this condition the moisture forms with the forming SO_2 gas a proportion also of H_2SO_3 , which tends to rapidly corrode the off-take flues or pipes where they are of sheet-iron, and the hoods also.

In other practice, the whole charge of 8 or 10 tons is added at once and the air-blast turned on at a low pressure of an ounce or two at first, but with about four ounces pressure later on when the ore has become more sintered together and thus impedes the passage of the air through it. The moistened ore takes fire from the hot ore first put in and slowly burns upward through the charge. Wherever it seems to be coming through more freely it is poked and covered with fresh ore so that it may be driven to come up elsewhere.

The ore soon becomes hot and glowing throughout its mass and over its surface, and sulphurous fumes are freely given off. Hinged doors at the sides of the hood give access to the interior for inspection and for poking the charge. The whole charge having burned through and the gases having in large measure ceased to coke off, the hood is removed and the pot is picked up by a crane and removed to the dumping-floor at the end of the building. Here it is inverted and the contents of the pot falls out upon the floor. Whenever any of it sticks it is cleaned or burned off, and the pot is returned to its pit for the next charge.

Pot-Roasting of Ore.

In the intervals between handling and charging the pots, the crane is occupied in handling the large lumps of ore putting them through a Blake crusher 24 by 36 in. in size. It is surprising to see how large lumps may be put through this crusher. Even where one end is inserted between the jaws with a little coaxing and sledging the pieces are soon put through. From the crusher the broken, and now thoroughly roasted ore is loaded to cars and transferred to the charging-floor. The roast is variable and ranges from 1.5 up to 5% in sulphur. With care practically all the ore is agglomerated. In those cases where this fails, as it sometimes may, the fine ore is moistened and mixed into the next charge.

The advantages of the process are :

1. The mechanical condition of the ore is such as to make it very acceptable to the blast-furnaces.
2. No fuel is needed in the operation.
3. The volatilization loss is practically nil while in ordinary roasting, and especially when the ore is agglomerated there is an appreciable loss. The loss in the Godfrey roaster is also nothing, since it is not carried free, and for the same reason the tonnage roasted is large. The costs of the operation are low since the material is handled mechanically and those costs are reduced with a larger number of pots used. The process, the rights to which in the United States have been purchased by the American Smelting & Refining Co., is coming into increasing use at their various plants.

The Action of Oxygen in Cyanide Solutions.

By H. JULIAN.

*A doubt has for some time existed as to the accuracy of the generally accepted idea that free oxygen is primarily essential for the dissolution of gold in cyanide solutions, according to the equation:

Experiments are described which go to show (1) that free oxygen plays no primary part in the reaction, (2) that any assistance given by free oxygen is of a secondary nature, and (3) that free oxygen exerts a retarding influence.

The experiments show that the galvanometer points to the presence of free oxygen as having a retarding influence on the dissolution of the gold, whereas the balance points to it being of material assistance. The cause of the two instruments not agreeing is discussed, and is attributed to the formation of local voltaic circuits. These, in the first instance, deposit hydrogen and oxygen, which, it may be assumed, becomes occluded at their respective electrodes until the systems are in equilibrium. It is pointed out that the cyanogen leaves the solution to combine with the gold rather than that gold particles pass into the solution, and it is shown that cyanogen does not leave the solution until the deposited oxygen has been occluded to a certain degree of concentration. The reason for this is that the expenditure of energy necessary to remove oxygen from the solution is less than that necessary to remove cyanogen; but when oxygen is occluded to a certain concentration, the expenditure of energy then necessary to cause the metal to occlude a further amount becomes as great as that necessary to begin to remove cyanogen from the solution. The available energy is obtained from the metal and solution, and it follows that when the solution is very dilute the available energy is too small to remove cyanogen, oxygen being then alone deposited. From this it may be conjectured that no metal actually combines with cyanogen until the solution has a certain minimum strength.

The presence of dissolved oxygen in the solution has a secondary effect in the process of dissolution, by oxidizing the occluded hydrogen produced through the action in the local voltaic circuits. This results in upsetting the equilibrium, and introducing into the circuits concentration gas cells, which soon bring about equilibrium again, but this time with oxygen at both electrodes at different concentrations, instead of hydrogen and oxygen. If, now, excess of dissolved oxygen diffuses to either of the electrodes the equilibrium is again upset, and an E.M.F. is generated by the gas cell in opposition to the E.M.F. generated by the metal couple; the net result being, of course, a current in the direction of the greater E.M.F. As the strength of the solution increases after a certain point, the E.M.F. due to the metal couple increases rapidly, whereas that due to the oxygen-concentration cell remains constant or increases only slowly.

The increase in the E.M.F. of the metal couple appears to be largely due to the formation of AuCy , a compound having a high potential, which acts as an electrode. This deposits in films, varying in density or thickness to a maximum with the strength of the solution. A couple results of Au-AuCN . After this stage of the process, when AuCy is formed, oxygen ceases to exert an influence. That is to say, the metal passes into solution by the AuCy dissolving in the potassium cyanide solution, as one salt dissolves in the solution of another.

The effect of the gas cell is best observed in highly

dilute solutions at ordinary or low temperatures. After a certain strength is attained, dependent on temperature, the effect of the gas cell is entirely masked. At the higher temperatures the E.M.F. of the gas cell diminishes, with a corresponding increase in the E.M.F. of the Au-AuCy couple. At boiling point the retarding oxygen effect of the gas cell on the dissolution of the metal practically disappears.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The specimen from Tombstone, Ariz. marked A. G. contains galena.

The mineral from Los Angeles, marked J. F. J. is black Tourmaline, of no value.

The nodules from Yavapai county, Arizona, marked C. W. N. are impure lime carbonate.

Specimens from Barstow marked C. K. are: No. 2. Epidote; No. 3. Garnet; No. 6. Rhyolite.

The black sand from Douglas Flat, Cal., marked J. M. E. is mainly Ilmenite mixed with quartz, garnet, zircon, and other silicates. No telluride.

The rocks from Phoenix, Ariz., marked W. L. H. are: No. 1. Sericite schist; No. 2. Altered feldspar; No. 3. Red jasper; No. 4. Quartzite; No. 5. Rhyolite; No. 6. Graphitic coal; No. 7. Black jasper; No. 8. Quartzite.

The minerals from Atwater, Cal., marked J. M. D. are: No. 1. Calcite; No. 2. Quartz and pyrite; No. 3. Pyrite, oxidized; No. 4. Chalcocite, cuprite, malachite, and azurite; No. 5. Pyrite, oxidized; No. 6. Melaphyr rock.

The tentative classification of the rocks from San Isidro, Honduras, sent by C. B., without a microscopic determination, is: No. 1. Andesite; No. 2. Basalt; No. 3. Basalt somewhat metamorphosed; No. 4. Basalt; No. 5. Altered andesite or melaphyr; No. 6. A contact metamorphic rock; No. 7. Altered rhyolite; No. 8 and 9. Contact metamorphics; No. 10 and 11 Andesite or basalt; No. 12. Altered andesite; No. 13 and 14 Altered rhyolite.

As a precautionary measure many of the large Austrian mines are equipped with a 'rescue chamber.' The excavation so named is a kind of strong-room underground, stoutly timbered, with only one entrance, fitted with a door that can be made absolutely air and water tight by means of india rubber accessories. The room contains three cylinders of compressed oxygen, the volume of which is 5,000 litres, sufficient to enable 30 men to breathe for three days. Inhalation gear is stored there, such as may be used for sending out reconnaissances and signalling parties. Tinned food, medicines, and first aid appliances and material are also kept in the apartment. The standard rescue room is capable of accommodating 24 men conveniently until the arrival of a rescue party within a reasonable time.

INEXPERIENCED TRUCKERS often try to stop cars by pulling back on them, instead of throwing a side pressure on them, so as to make friction between the rails and flanges. This is far more effective and much less trouble.

*Abstract from *British Association Report*, prepared by the author and published in the *Journal* of the Chemical, Metallurgical and Mining Society of South Africa.

Notes From Cloncurry.

Cloncurry is in Queensland, Australia; it is important as a centre of copper mining that is likely to become more active when it gets a railroad outlet, in the near future. About thirty years ago a good deal of native copper was mined at Cloncurry, but now the principal ores are sulphides, with masses of oxidized material at surface. One of the most promising prospects is the Mt. Elliott mine, which has a big outcrop rich enough to be sacked for shipment on camels, as shown in the accompanying photograph. They carry it 200 miles to the rail-

Camels Laden With Ore From Cloncurry.

head. It is a dry country — hot and infested with flies, so that everyone wears gauze below their hat-brim. Occasionally in the primeval forest or 'bush,' a pool survives under the shade of the big eucalyptus, as is illustrated in the second photograph. Cloncurry is one of the mining districts awaiting the conquest of modern industry. There are big outcrops and much copper ore lying loose on the surface, rich enough to warrant vigorous exploration underground. We owe these notes to Mr. Edgar Hall, of Stanthorpe.

Mining in Brazil.

Foreign companies, in order to do business in Brazil and obtain authorization therefor from the Government to work in the country, must present a copy of their statutes, signed by the incorporators of the company.

There must also be presented a list of the shareholders with their names, professions, residences, and the number of shares each subscribes; a power of attorney, made out by the directors or incorporators of a company, naming a representative in Brazil with powers to represent them before the Government, law courts, or with private individuals. In this power of attorney power must be given the said representative to sign a petition requesting the Government to authorize the company to work in Brazil and all other acts necessary for the purpose.

Before foreign companies, established for the purpose of working in Brazil, begin operations they must deposit in the federal treasury a tenth part of their capital; this deposit can be recovered by the company immediately after its statutes have been deposited in the archives of the Commercial Junta. For registering in the Commercial

Junta, companies will pay a stamp tax of \$100 Brazilian currency, which at present equals exchange about \$335 American gold, for each \$1,000,000 of the capital of the company, reduced to Brazilian currency at the exchange of the day the statutes are registered.

All documents must have signatures certified to at the Brazilian consulate of the place where the company was established, or if there be no consulate at that place, then (for the United States) at the consulate-general in New York City.

Expenses, besides the above-mentioned taxes, consist of translation of the documents into the Portuguese lan-

guage, publication of the statutes, and the decree authorizing the company to operate and do business in the official gazette, in which governmental notices are made public, and for stamps to be placed upon the documents filed with the Government, said excise stamps being necessary to give them legality.

It may be added that concessions for mining in the several States of Brazil are granted by the several State governments, the only cost being the State taxes, which are imposed annually. With actual working con-

cerns, acting in good faith, such imposts are not excessive, as a rule. In general, also, it may be said that there is no difficulty experienced in obtaining these concessions.

THE illustrations preserved of Egyptian iron manufacture show that the process was precisely the same as that

In the Australian Bush.

still obtaining among Ethiopian races. On a stone, preserved at Florence, a negro slave is depicted working bellows from which the blast is conveyed by a bamboo pipe to a shallow pit in which the iron is smelted. In a second illustration is shown the forging of the iron by hammering it with a rounded stone on a stone anvil with wooden base. It is clearly proved by pictures on Egyptian tombs that bellows were in use in the 15th century B. C. This shows a distinct advance over the primitive method of smelting on a windy hillside; and it is curious to note that even at the present day furnaces with a natural air draught are used for lead-smelting in Bolivia.

Underground Surveying.

By BLAMEY STEVENS.

*Some difficulty is usually experienced in accurately transferring the meridian to the bottom of a narrow shaft several hundred feet in depth. The ordinary method of transferring a meridian into a mine is to set up the transit at a station fixed at the mouth of the shaft and, after taking a back-sight on the previous station on the surface, to take a fore-sight down the shaft, the line of sight being made as much inclined to the vertical as possible. Having ascertained the intervening distance, the transit is set up at the bottom station, a back-sight taken on the top station, and the survey then carried into the galleries of the mine.

In sighting from both ends of the same highly inclined line, it will be found that errors due to the line of sight not being perpendicular to the horizontal axis are eliminated if the readings are made with the telescope in the same position at both sights, whereas errors due to inclination of the horizontal axis are eliminated if the readings are made with the telescope direct when at the top and reversed when at the bottom of the shaft, or the reverse. When it is impossible to sight up a shaft on account of its being too wet, two or more points can be set in line at the bottom of the shaft by means of the instrument when at the top, and these will determine a line of known azimuth at the bottom of the shaft.

In some cases a wire is stretched horizontally across the bottom of the shaft and as far back into the workings as possible, the wire being carefully aligned by the instrument at the top. This method may admit of even more accuracy than that of taking a back-sight to the surface from a station established on the bottom of the mine. Errors due to a slight inclination of the horizontal axis are not important when this method is used and for that reason it is also useful in cases where a sensitive striding level is not to be had. The effect of a slight inclination of the horizontal axis is simply to shift the line slightly to one side but parallel to the true position.

When no extra telescope or eccentric bearings are to be had, an ordinary transit with a prismatic eyepiece attached may be used to drop the meridian down a vertical or highly inclined shaft, provided it is not so wet as to prevent sighting upward from below. To accomplish this a thin wire is stretched horizontally across the top of the shaft at a known azimuth; the wire should be prolonged one or both ways in order to give a good base-line. Two points may be fixed at the top of the shaft if preferred. The transit is then set up on the bottom and it is brought by trial into the same vertical plane as the wire. The striding level is used in both positions and the transit is used in both the direct and reversed positions to eliminate errors.

It is to be noted that in mining and mountain work slight errors occur in sighting up steep inclines owing to the refraction of the atmosphere, but this is so slight that it does not effect the transfer of the meridian and is never taken account of.

Surveying in a mine is necessarily a process of traversing, for only the working passages are available for lines of survey. The line of traverse is not always in the centre of the passage but is often varied from it in order that the longest possible sight may be taken. In the tortuous passages of a mine it is frequently necessary to take short sights on the main traverse and since the azimuth is transferred to distant connections through these short lines great care should be exercised. The positions of the walls of the passages are noted as the work pro-

ceeds and are sketched in approximately on the plot. After the main traverses have been run, the surface boundaries, if touched, may be accurately established and the stopes and working places surveyed by more convenient and less accurate methods, from the stations already established.

It is often convenient in underground work to take the azimuth from an estimated general strike of the vein; for the direction of the meridian is of no importance in the actual working of a mine, while the direction of most of the passages will usually vary only a few degrees from the strike, and thus all traverse calculations are simplified.

A speedy and convenient manner of running an underground traverse is to use three tripods having leveling heads and centering plates like those of the transit. The transit fits on to any of these heads and while it is attached to one of them the other two are surmounted by lamp targets in which the sighting centre has exactly the same position as the sighting centre of the transit would have if set on the same tripod. These tripods are placed vertically over or under the stations and the transit is attached to the middle one. When the transit head is moved from the middle to the foremost tripod a target takes its former place and the hindmost tripod is brought ahead of the transit and set up on the new forward station. The lamp behind the plumb-target or plumb-line should give a diffused illumination of considerable area so that it may be easily found with the telescope and so that it may render the cross-hairs of the telescope plainly visible. In cases where the illumination of the object is such that the hairs cannot be distinguished, a light is thrown obliquely into the telescope tube in front of the hairs, preferably by a tube-reflector in front of the object glass.

Sometimes a brass lamp with a small central flame, called a 'plummet-lamp,' is suspended in place of a plumb-line and the flame is sighted at, but this is too small a target for quick work and the surveyor may also mistake other lights, such as miner's lamps or candles, for it when sighting through the telescope.

The station point is established either on the floor or the roof, according to the character and condition of the mine; the chief object sought is permanence of position rather than convenience in getting at the point for future use, which is of secondary importance. In a vein mine a timber in the roof, especially a stull, is often more permanent than the floor or rock roof, but any timber is likely to be moved by the miners. The hanging wall is a good place for the station, but if the inclination is small as in a coal vein, the foot-wall or floor is best.

To establish a station, get a miner to make a drill-hole about six inches deep, more or less, according to the hardness of the rock. Cut a wooden plug to fit this hole tightly when hammered in dry, and do not let any more of the plug project than is necessary. Small screw-eyes make good roof station-points from which to suspend the plumb-line, but where the lines are short a finishing nail bent to a sharp angle is better as the plumb-line will then always hang in exactly the same position. For measuring between stations a 100-ft. steel-ribbon tape, divided to hundredths of a foot is used; but for long straight tunnels and shaft work, a longer steel-wire tape is more convenient.

A FACT in itself has no significance; neither have a thousand facts. What give facts their value is their relation to each other; for when enough have been collected to suggest a sequence of cause and effect, a generalization can be made which scientific men call a 'law.' The law amounts only to this, that certain phenomena have been found to succeed each other with sufficient regularity to enable us to count with reasonable certainty on their recurrence in a determined order.

*From advance proofs of a chapter in a text-book on surveying prepared by George H. Hosmer and C. B. Breed, of the Massachusetts Institute of Technology, Boston.

The Experiences of a Tenderfoot.

By An Occasional Contributor.

Being superintendent of a mine is not such a strenuous proposition—if you have the board of directors solidly behind you. The way I came to be superintendent is scarcely worth mentioning. Several of my people, and our friends, invested in a mine in the West, and they naturally wanted to place someone in charge whom they knew and could trust. As my own people held a large block of stock, the choice fell on me as the most available among several eligibles. I had received a good education, and had already made a fair success in a mercantile way. I had the direction of a number of men clerks, office boys, and salesmen, for some time, and had handled the business admirably—so I was told. When I was asked if I would go out West and take charge of our mine, I looked upon it as an opportunity, and accepted it, particularly as I believed it would broaden my views and experience—not that I felt the need of it—but it was a change, and I thought I should like it. Mining for gold appealed to me. We were all struggling, in one way or another, to get gold, and here was a chance to actually dig it out of the ground. What ambitious young man would reject such an offer?

After several days of preparation, I left my Eastern home, carrying letters to the gentleman then in charge of the mine, to a banker, and to others in the little town where our mine was situated in Montana.

I arrived at the station where I was to leave the railroad late at night. The stage was to take me the following day to the mine, about 50 miles back in the mountains. I arose early and dressed suitably for the stage-ride, and for my entree into the mining camp. My outer apparel consisted of a blue flannel shirt, corduroy breeches, high laced boots, and a felt hat with a brim of rather liberal dimensions. I wore a sack coat, and about my waist was strapped a leathern cartridge belt with a supply of ammunition for my revolver, which I also wore—for I understood that there were some rough characters at the mines, and naturally I did not wish to be placed at a disadvantage.

The stage-ride was a delightful and novel experience. For several miles we rode across the valley through which the railroad passed, gradually ascending toward a grand range of mountains whose higher peaks were covered with snow. In these mountains, at the little town of Lynchtree, was our mine, and as we rode rapidly along the valley road, the stage-driver, who was an intelligent and entertaining fellow, endeavored to point out to me, among the numerous peaks and ridges, the particular eminence beyond which our camp was situated. I got much useful information from this driver, about the country and its people. He told me all about the mines—he had, in fact, worked in them himself. He also said it was a good thing I had my gun along, as we might be held up, which he explained meant we might be stopped and robbed by highwaymen—“road agents,” he called them. This reference to my pistol was, no doubt, intended to allay any fear I might entertain, but it really made me most uncomfortable throughout the balance of the trip, for, though I was well armed, I didn't relish being shot from ambush, which was the practice of these highwaymen, so my informant said. It was mostly, however, the down stages, he explained, that were held up, as these carried the bullion. Once we passed a man on the road, who, I thought, had a most villainous countenance, but who, the driver said, was only a charcoal burner, who lived in the vicinity, on his way to the valley for supplies. All the same, I should not have cared to meet him alone on this mountain road, when unarmed.

We had lunch at a wayside station, about noon, and after changing horses, we proceeded further into the mountain fastness. The hills had grown higher and higher as the day wore on, and the air was now becoming cool and decidedly bracing. We drove through forests of pines, maples, and aspen, and crossed rushing streams of beautifully clear icy-cold water, which the driver said were full of fish. After a time we passed over a ridge and descended a long grade, at the foot of which we came to a stream of water, running red as blood. I was astonished and expressed my surprise to the driver. “That's tailings,” he said, “from the mine up here, where you are going. I don't want to be inquisitive,” he continued, “but I suppose you are going up to examine the mine, ain't you?” I then told him my business—that I was the new manager, and expected to make my home in the town for an indefinite time. I didn't know whether I had offended him in some way or not, but he had very little to say after that and volunteered no further information, of which he had previously been so generous, though he did not hesitate to answer my numerous questions. He said the mine was a good one. All it required was some smart fellow who knew what he was about, and it would pay like a bank. I assured him of my intention to do the best with it that could be done. I have often wished that I had not talked quite so freely with that stage-driver, as I sometimes think he did not keep all I told him to himself, but that was several years ago.

Late in the afternoon we rounded a bend in the canyon, and there—a mile or so away—I saw a number of buildings, mainly white cottages, clinging, as it were, to the steep hill-sides; larger buildings with curious square fronts, and back of all a group of huge red buildings with white trimmings. It was certainly a picturesque and pleasing sight to an Eastern tenderfoot, for I had already learned that a stranger to the West is known by this strange appellation.

As we approached the town, the driver shook out his lines, cracked his long whip, and we dashed up the single street in a cloud of dust, attracting the attention of every person apparently, for every one in sight stopped to look at us, and as we neared the centre of the village, I noticed the greater number of citizens in the vicinity hurrying toward a common point—the post-office and stage station. I was somewhat surprised to see so many well-dressed people. White shirts and collars were abundant, and I supposed I had struck the place on a holiday, or some special occasion, but what surprised me still more was the fact that not one of the men I saw appeared to have a pistol—a ‘gun’, as the driver called it.

Upward of a hundred people stood about the sidewalk and in the street as we drove up, and others continued to come. The driver said he would take me up to the hotel directly, so I sat still, while the crowd eyed me curiously, and a few jocose remarks were passed between the driver and his friends in the crowd.

One fellow inquired with a grin: “See any hold-ups this trip up?” “No,” said the driver, “but we're due to get one, I guess.” Whether this was intended for my benefit, I did not know, but I endeavored to look unconcerned. I saw that these people were unabashed in the presence of strangers at all events.

The mail-bags and express-boxes were quickly thrown out, and we went on to the hotel. I was assigned to a small, but clean and comfortable, room. I concluded to lay aside my pistol for the time being and made some inquiries concerning those to whom I had letters of introduction. I called on the banker, and he kindly offered to accompany me to the mine. There I met the superintendent, Mr. Jones, whom we found in the office. He

wore a suit of overalls, much soiled with reddish dirt, and covered with spots and blotches of what I first thought to be dirty white paint, but which I soon learned to be candle grease.

I handed him my letter, and he said he was delighted to meet me, though he didn't look it. My coming had been announced. We sat in the office and talked a long time. He told me how things were going, and declared again his pleasure at my arrival, as he said he had for some time been wanting to visit his people in California, and that as soon as I had 'learned the ropes' he would like to go to see them. So I told him there would be no difficulty about that.

The following morning I went to the office and Mr. Jones suggested that we go underground. I expressed my willingness. He then said I had better change. I thought at first he meant my mind, but he explained that he referred to my clothes. He produced a suit of blue jeans only a little less dirty than his own, and I donned them gingerly. He then gave me a lantern, while he took a candle in a curious looking sharp-pointed contrivance he called his candlestick. We walked up toward a large red building from which came a continual roar like that of a railroad train running over a bridge. He pushed the sliding door open and stepped inside, I following. The sound was simply deafening. I looked at him, and he said something I could not understand. I shook my head, and he bawled close to my ear: "Mill." He then beckoned me to follow him and we climbed up a series of steps from floor to floor, and finally came out of the building onto a high covered trestle, along which we walked, coming out into a smaller building, where it was comparatively quiet. I noticed a huge engine, attended apparently by a man who, seated within reach of a number of levers, seemed to be doing nothing in particular. I was spared the necessity of making any inquiry by a large sign over his head which bore the legend: "Don't talk to the engineer," so I said nothing.

As I looked around, while Mr. Jones was talking with some men, a great gong suddenly rang one stroke. Immediately the man in the chair seized two levers. There was a slight hiss of steam and the huge machine began to revolve, slowly at first, then faster and faster. The engineer fixed his eyes on a great disc, where a pointer slowly moved around like a single hand on the dial of a strange clock. Suddenly he moved one of the levers, the engine slowed up somewhat, when, to my surprise, I heard a crash behind me. I looked around quickly and saw a strange looking box of iron shooting upward into a great frame of timbers. It moved more slowly and then automatically overturned, spilling its load of rock into a bin of some sort with a great roar. The box descended and quickly passed out of sight into the yawning black hole into the floor, that I had not noticed until now. As the box came down to the level of the floor I saw a sort of lattice work of steel that had been above it, caught on the floor in some manner and remained there while the box—I tried to think of the name of it, and remembered that this must be the 'skip.' As the skip passed down the shaft, clouds of ill-smelling steam poured out of the shaft through the bars of the lattice work, which I now understood was intended to prevent careless persons from falling into the hole.

"Well," said Mr. Jones, "If you like, we'll go below on the next skip." Then turning to a man standing near, said: "This is Mr. Ham, the foreman." Mr. Ham wiped his hand on his breeches and extended it. I took it and he shook mine heartily. When he let go I noticed that my hand now bore some of the stains of his toil.

The gong clanged again. I counted one, two, three;

then, after a pause, one. Again the engine hissed and the drum commenced to revolve. This time it moved more slowly, and it took some time to bring the skip to the surface. When it finally appeared, there were two men on it. Both wore yellow coats, anything but clean, and dripping with water. Mr. Jones assisted me in putting on a yellow oil coat, but I was pleased to notice that it was quite new. A hat, of similar material, and in shape like those worn by firemen, was provided and we stepped onto a platform of boards placed across what I correctly guessed to be a skip. Mr. Jones grasped a wire cord, and rang a gong 5—3—2. Almost instantly we began to sink downward. I caught a bar of iron over my head, as directed by Mr. Jones, and we went down, down, down, as it seemed to me, almost to Hades. Twice I noticed the flash of lights in what seemed to be a room way down underground. I thought of many things during that brief trip of less than a minute, but my chief thought was, what would happen should the rope, that held us suspended in the black, cold hole, break. I held a cigar between my teeth, and was surprised when the skip finally stopped opposite a well-lighted room, to find I had bitten it in two. I said nothing, but threw it away.

On that, my first visit underground, I saw many strange things, things which since have become very familiar, but at that time it would have required little to have persuaded me to return to my Eastern home; but in time I grew to like it. The rapid flight up or down through the shaft, which no longer had any terrors for me, the daily trip through the drifts, the climb up into stopes, the fearful racket of the machine-drills, the study of the vagaries of the vein; the handling of the men; the mill with its deafening roar. All became dear to my soul and to be where I could not see or hear the sound of the mines was to be dissatisfied and unhappy.

VANCOUVER ISLAND.—The principal product of Vancouver Island is coal, of which there were mined during 1905, 993,899 tons. Of this amount 380,332 tons were sold in Canada, 427,698 tons exported to the United States, and the remainder used for local consumption. The amount of coke produced was 15,661 tons, of which 5,410 tons were sold in Canada and 4,300 in the United States, including Alaska, while 5,950 tons were added to stock. In 1904 the mines turned out 1,023,013 tons of coal and 19,371 tons of coke. The total coal sales show an increase of 24,000 tons, or 3% over 1904. The sales to the United States amounted to 53% of the total, most of which was disposed of in the California market, the remainder going to Alaska, where the recent developments in metalliferous mining seem destined to produce a constantly increasing market for this article.

Of the two smelters the one at Crofton was not in operation during 1905, but blew in on January 6, 1906, and is treating ore from the Britannia and other coast mines. The Tye smelter at Ladysmith was in blast 164 days of 24 hours each, and produced 38,960 tons of smelted ore. The value of the ore smelted, less refining charges, was \$506,600. The copper product of the island in 1905 was 3,437,236 lb., a decrease of 2,523,357 lb. from 1904.

MEASURING FLOW OF AN ARTESIAN WELL.—Under conditions where a weir could not be built, a novel way of measuring the flow of an artesian well was devised. Forty feet of 10-inch pipe was screwed into a 90° elbow on the pipe where it came out of the ground, and a hand force-pump attached to a small hole tapped into this pipe. The force-pump drew a red aniline liquid from a pail and injected it into the stream, where it was carried along with the water and at the same rate. By means of a stop-watch and the known carrying capacity of the pipe the flow of the well was easily determined.—*Iron Age*.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

ORE-HOIST.—No. 830,836; Charles W. Hunt, West New Brighton, N. Y.

In an apparatus of the character described the combination with a chute and a vertically movable skip of guides for said skip standing at a distance from the end of the chute to permit the skip to clear the same in its movement and carried inward toward the vertical plane of the chute below the same to guide the skip below the end of the chute.

MEANS FOR SURVEYING BORE-HOLES.—No. 830,730; Hugh F. Marriott, Parktown, Transvaal.

An instrument for surveying bore-holes comprising a casing, a revolvable portion pivoted on its longitudinal axis in said casing, a plumb-bob pivotally carried by said revolvable portion, the pivot thereof being at right angles to the longitudinal axis of said portion, a switch arm carried by said plumb-bob, a commutator carried by said revolvable portion over which the switch-arm is caused to travel as the revolvable portion is inclined, said revolvable portion being so weighted that it moves into a position to cause said switch-arm to move in a vertical plane, and means for transmitting the indications of the movements of the switch-arm over the commutator, substantially as described.

ROASTING-FURNACE.—No. 831,166; Frank Klepetko, New York, N. Y.

In a furnace having a plurality of hearths, a hollow shaft passing through the hearths, a series of hollow arms radiating from said shaft and extending into the several hearths,

a feed-pipe passing longitudinally through and discharging into the shaft, an outlet-pipe located within the shaft, and a series of branches leading to said outlet-pipe and communicating with the interior of the hollow arms for conducting the circulating medium from the arms into the outlet-pipe, substantially as set forth.

ROCK-DRILL.—No. 830,744; Charles H. Shaw, Denver, Colorado. Filed September 21, 1905.

In a drill mechanism, a casing, a hollow drill-shank inserted in the casing and provided with a lateral opening, a cylinder formed within the casing adjacent the shank, a hollow piston mounted to reciprocate within the cylinder, an elastic packing carried by the piston and in contact with the shank, a duct forming communication between the casing and the cylinder and opening in the rear of the piston, and means to admit fluid under pressure to the casing.

DUPLEX STEAM-PUMP.—No. 830,723; Johan Kofoed, Christiania, Norway.

In combination with the steam-cylinders, pistons and piston-rods of a duplex steam-pump, of a valve-chamber common to said steam-cylinders and connected therewith by steam-passages, a valve revolvably arranged within said chamber and provided with steam-passages and having its stem projecting beyond the said chamber, cams on said stem and means on the piston-rods adapted to alternately engage said cams on said stem so as to impart an intermittent rotary movement to the valve in one and the same direction, thereby alternately admitting and exhausting steam to and from the said steam-cylinders respectively.

ORE-FEEDER.—No. 831,595; Forest H. Blanding, San Francisco, California.

In an ore-feeder, the combination of a rotatable feed-table, of a rock-shaft, of a gear loose on said shaft engaging the feed-table, of means secured to the said shaft for frictionally engaging with the gear to actuate the same with the movement of the rock-shaft, and cam-actuated devices for imparting motion to the said rock-shaft.

A Gasoline Mine-Hoist.

The improvements in mining hoists have been rapid, and in the last few years they have reached unexpected proportions. Of the different modes of power used in the average metal mine there is practically no comparison with the gasoline, distillate, or alcohol hoist. The last mentioned fuel has yet not played so important a part in the mines of this country, but is being used extensively in South America.

The advantages of a gas-operating hoist are many. It requires but little water, that being used for the cooling of the engine cylinder. The fuel is needed in such small quantities that it can be carried to any point and to those mines that are difficult to reach. There is no consumption of material outside of the small amount of fuel that is used, and it enables plants to keep in operation that would otherwise be compelled to shut down in some seasons, owing to climatic conditions that make the mine inaccessible.

We illustrate here the improved standard single-drum Witte hoist manufactured exclusively by the Witte Iron Works Co., of Kansas City, Mo. This hoist operates on either gasoline, distillate, or alcohol, and while it is well known, and is being used extensively in all mining regions of the United States and other countries, the attention of our readers is called to a few points mentioned in the catalogue issued by the manufacturers. The engine-bed is built separate from the hoist-bed, thus decreasing the weight by dividing the shipment for transportation and, where necessary, it can be used as an independent power separate from the hoist. The engine-shaft is extended so that an additional pulley can be added for operating a compressor. The levers, instead of facing the drum, either face the engine or rope; they are reversible and are mounted on the hoist-bed proper, so an independent base is not needed. The thrust-screw is operated by a long lever giving powerful leverage and a great factor of safety over the old short hand-lever. The speeder-lever, the friction- and the brake-lever are all in convenient reach of the operator, who may at the same time attend to the ropes and buckets. The action of the friction and brake is positive. They can be locked at any point or thrown in at a moment's notice and, by means of the speeder, attain double the usual speed, an advantage particularly desired in prospecting equipments. The engine is equipped with wipe-feed oil system, so that the operator can at a glance see that every bearing on the engine is being lubricated. These hoists are manufactured in many sizes, with speeds arranged in proportion to load, the ratios being changed to suit the requirements of customers. One particular feature set forth in the catalogue is the absolute guarantee of safety in the operation of the hoist, its efficiency, and economy in fuel, and that all defective parts will be replaced for a period of five years. It is also noted that this hoist is not overweighted or top heavy, being built in a permanent manner, applying the weight where it is most needed without making it cumbersome.

Publications Received.

THE ABENDROTH & ROOT MFG. CO., of Newburgh, New York, has issued an attractive hand-book on Root Spiral Riveted Pipe and Root Water-Tube Boilers manufactured for mining purposes. The book contains many valuable data on hydraulics and a useful price list.

Commercial Paragraphs.

THE LOMBARD-REPOGUE ENGINEERING CO. has issued a bulletin describing its water-wheel governors. This is an important feature of any hydraulic installation.

THE AMERICAN SAFETY POWDER CO., of San Jose, reports the receipt through its contracting agent of a gratifying number of orders and inquiries for Aspeco.

THE MAYER FACTORY of Milwaukee uses annually 415,612 hides of steers, cows, calves, goats, horses, sheep, and kangaroos. In the ordinary whirl of business people do not realize the enormous industry represented by a large boot and shoe company.

THE SAMSON MFG. CO., 1734 Fifteenth St., Denver, Colo., has been in business the past two years, and the sales of crushers have been 59 and the inquiries for these machines are increasing daily. This company is now putting on the market a smaller sized machine, which promises to be popular.

THE MARION STEAM SHOVEL CO., of Marion, Ohio, reports the receipt of one order for twenty-three Model No. 91 and six Model No. 60 shovels to be used in the Mesaba iron range of Minnesota.

This order is particularly gratifying, as it was obtained in the face of strong competition and also for a district in which the merits of various machines have been thoroughly tried.

THE DALY-JUDGE Mining Co., of Park City, Utah, has let a contract for furnishing a 12 by 24 in. Reynolds Reliance Corliss engine of the belted type to the Allis-Chalmers Co., of Milwaukee.

The new unit will operate at a speed of 130 r.p.m., non-condensing, under a steam pressure of 110 lb., and will be belted to a countershaft running concentrating tables and an electric generator.

THE PACIFIC HIGH EXPLOSIVE CO., a New York corporation, has purchased 50 acres of water-front land near Oakland, Cal., on which it is erecting buildings for the manufacture of Trojan Non-Freezing Powder, regarding which the following statement is made: "This is a new explosive having all the strength of nitro-glycerine dynamite, but without being effected by heat or cold. Tests have been made, by placing this powder in ice for 48 hours, and when shot, its disruptive power had not diminished in the slightest degree."

Books Received.

A novelty in books is found in the TECHNICAL DICTIONARY, printed in six languages—English, German, French, Russian, Italian, and Spanish. In addition to the names of mechanical and scientific objects, the work is illustrated. Its use is restricted to machines and tools, but suggests the possibilities of other compilations in the same direction. The book is an innovation and decidedly interesting. Sent by the MINING AND SCIENTIFIC PRESS upon receipt of price \$2 net. McGraw Publishing Co., New York City.

STRAY CURRENTS FROM ELECTRIC RAILWAYS is the title of a new work by Dr. Carl Michalke. All are interested in the strange and remarkable effects of electrolysis caused by currents escaping from electric railway wires and tracks. Mysterious electric currents are found in so many places that they are a source of constant interest and often of annoyance. This little book deals with these fugitive currents and their effects. Sent by the MINING AND SCIENTIFIC PRESS on receipt of price \$1.50 net. McGraw Publishing Co., New York City.

Improved Standard Single-drum Hoist.

Editorial.

THE EXTRAORDINARY PROSPERITY and expanding industrial activity of the United States is evinced in the continued and increasing shortage of railroad cars, the supply of which is quite inadequate to the moving of the freight that is awaiting transport. In some departments of business this condition threatens a blockade of the material required for manufacture. Both the basic industries, that of grain and that of iron ore, are handicapped in this way. Another sign of the times is the strain on the money market; New York has tried to raid London for gold, and London is scouring the rest of the world for the medium of exchange.

NEVADA now holds third place in the production of gold, being second only to Colorado and California. At the present time one mine at Goldfield is producing \$1,000,000 worth of ore per month. And there are so many new districts in course of development that the future is full of promise.

OUR DISCUSSION DEPARTMENT gains dignity this week from the letter of Mr. D'Arcy Weatherbe, in the course of which he gives much valuable information on dredging for gold. Mr. J. H. Curle wrote an informing and also questioning letter in our issue of January 27; he now gets a full and trustworthy reply to his queries, together with some fair criticism of his own opinions. These two contributions, together with that of Mr. C. W. Purington, give as much real information as the several books on the subject compiled by amateurs during recent years.

THE ANNUAL STATISTICS of the State Mining Bureau are published on another page. They exhibit several interesting features; the continued prominence of gold mining, the importance of the oil industry, and the growth of copper mining. In the last of these there was not the gain that was expected, and that has taken place during the current year. The copper mines of Shasta county are destined to play an important part in the industrial advancement of California. Nevada county is still first in gold production, thanks to two or three old reliable mines, such as the North Star and the Empire. One portion of the mineral product has become of much enhanced importance, namely, the structural materials. It seems thriftless for California to import cement from Germany when she possesses rock suitable for the purpose, and it is wasteful to destroy our forests when good clay is available for making brick. These departments of industry ought to be strongly stimulated by the necessities of San Francisco and her neighboring cities on the Bay.

THE COMPLETION of the railroad from Cobre to Ely, constituting the Nevada Northern Railway, was befittingly celebrated recently. On that occasion Mr. Mark

L. Requa delivered an address, an abstract of which we give elsewhere, for it contained many suggestive statements. He knew there was a big copper deposit at Ely, but a deposit is not a mine; it was low-grade material, which could only be made pay-ore by the erection of expensive reduction works and the construction of a railroad. Neither was justified unless an adequate tonnage of a certain copper content was available. It was a question of systematic sampling; first, by hand; then, in larger lots in an experimental mill. While these tests were in progress, vigorous exploration laid open increased reserves of ore. It was good mining and sound business. If Mr. Requa and his professional associates, Messrs. F. W. Bradley and J. H. Mackenzie, have made a fortune apiece, they have deserved it. It was the logical result of skill applied to circumstance.

The Smelting Monopoly.

At the recent Mining Congress an effort was made to ventilate the grievances of mine owners in regard to excessive—so it is claimed—rates for treatment levied by the smelter trust, namely, the American Smelting & Refining Company. In order to prevent a one-sided and therefore useless presentation of the subject, it was arranged that the local manager of the smelter people should be present and reply to the arraignment of his employer. The attack was prepared by Mr. E. M. De la Vergne, a State Senator and a representative mine operator of Cripple Creek, while the defence—which was anything but meek—was made by Mr. Franklin Guiterman, a technical man of the highest standing in the profession. The effort to secure a fair discussion of a complicated matter was a failure. On the one side there was too little judgment in the criticism offered; on the other, there was the confident assertiveness of a man who knew his own business and thought it best for others to attend to theirs. It was not the best audience for such a debate; the mine operators in Colorado are naturally irritated because they have only one market for their ores where formerly they could get four or five bids on every carload. Even if the ore buyer be a saintly personage, one naturally dislikes to be compelled to deal with him only; it is so much pleasanter to have a little choice in the matter and to be able to ship the ore to different people, as circumstances direct. Furthermore, Mr. Simon Gugenheim is a candidate for the senatorship; he has had a political bee in his bonnet for some time—ever since he was nominated for lieutenant governor about eight years ago. Naturally, he has incurred the bitter opposition of the group of politicians who have kept Colorado in a condition of turmoil for the last decade; in consequence, he and the smelting company are being viciously attacked in the Denver papers. And, frankly, we think that the average citizen of Colorado has a right to object to the senatorship going to a man whose chief qualification is his wealth; it may be that his wealth was not won at the expense of the State, but that it is the result of an honorable business activity which has enriched both the smelterman and the community, nevertheless it is about time that senatorships were no longer put up to auction.

These considerations and others into which it is needless to go, made it impossible for the convention at Denver to offer a fair hearing to any discussion on the rates of treatment. It was a pity; for an open debate might have killed many of the fallacies rampant on this question and it would have given the smelting company an opportunity to speak to the public squarely and thus remove some of the prejudice created by irresponsible politicians. As we view the matter, there are three features that stand out prominently. In the first place, much of the talk on sampling and ore settlements overlooks the fact that the whole technical process of assaying and sampling is based on the doctrine of averages. Mine managers are apt to ask for a settlement on the highest assay and to demand a re-sampling when the smelter assay is lower than theirs. It is hard for a seller of ore to believe that the highest assay does not represent the most accurate result. On the other side, the smelter manager often insists on hand sampling or other methods that introduce the personal equation and subvert the doctrine of averages. No one ignorant of the technique of sampling and assaying is in a position to discuss this subject. It is one that should be under the control of inspectors or other persons—if such were obtainable—who could make it their business to detect chicanery on either side. Next comes the question of competition. The mine operators are largely to blame for the absence of it. If an independent smelter starts to work—for example, at Golden or Salida—they give it a warm welcome and send their ore to the new market, which gives them cheaper treatment. Then, in the ordinary course of human events, the American Smelting & Refining Company lowers its rates so as to take the business from its competitor. Promptly, the mine operators desert the opposition. Their guide is self-interest; so is the smelting company's. The public welfare or the prosperity of the State or the development of a mining district are all made subservient to the exigencies of business. Sentiment is conspicuously absent. Finally, there is another aspect of this question. The strong position of the smelter combination is based, not on its huge capital, its ore contracts, its many reduction works, but on a monopoly of talent; take away the highly skilled and widely experienced metallurgical specialists and constructing engineers that are now the active force in its manifold operations and it would become merely a big stock company, controlled by a number of clever capitalists. We do not under-rate the ability and integrity of the particular family identified with the smelting combination; but they are not technical men, they are shrewd financiers. It may seem that their strength is in their money, but money is plentiful nowadays; they owe their dominating position to the corps of technical experts whom they have retained. Other metallurgists are being trained elsewhere—there are enough independent smelters for that purpose; and if the big corporation should develop a tyrannical spirit or become in fact what it is now loosely termed—a trust, a monopoly contrary to public good, calculated to cripple the development of the mining industry—then it would lose the mainstay of its strength. First-class technical ability is rarer than money. The matter will regulate itself.

By the Way.

THE INCORPORATION OF TRADE UNIONS.—The Massachusetts Bureau of Statistics of Labor sent a number of questions to four classes of persons—employers, labor leaders, lawyers, and 'the public.' The last-named class was made up largely of college presidents, professors, and editors. Of 963 letters sent out, replies were received from 301, this number being made up of 96 employers, 81 labor leaders, 71 'public,' and 53 lawyers. The report gives the summation of the results of the inquiry:

Employers believe that trade unions should incorporate because the better class of members would be individually active in the management of the union for the purpose of conservative action leading to continually increased strength in their standing before the community.

Labor leaders, on the other hand, believe that trade unions should not be incorporated because the individual member would be held responsible for the actions of the organizations, also because the organizations would be held responsible for the action of the individual member, or, in other words, the responsible members would be liable on account of the irresponsible ones. They are further opposed to incorporation for the reasons as they advance, that their funds would be liable to attachment, and that manufacturers would possess more power in the courts than the unions because they could employ the best available legal talent to advance their claims.

The public view is that incorporation is desirable both from the standpoint of the public and unions, for, while it might limit to a certain degree the freedom of action of the unions in ways which do not now exist, and at times the unions might be embarrassed by legal proceedings directed against them, these disadvantages would be more than offset by the greater willingness of their employers to deal with the unions when they feel that the unions are legally responsible bodies. In view of certain decisions of the courts it is thought that the responsibility desired may already exist, but there would be no doubt about it if the unions were incorporated.

The legal profession, which is perhaps in a better position to judge impartially of the matter than any other, for the reason that it may have as clients both employers and employees, is of the opinion that it would not be inimical to the interests of trade unions to be incorporated. The legal profession declares the difficulty with trade unions at present to be their irresponsible character. It is claimed that they frequently fail to show any regard whatever for their agreements, which is the first essential in commanding public respect. Incorporation would mean responsibility, and actions by responsible unions would be accepted as a pledge of good faith by responsible employers.

THE UNION LABEL.—The following is taken from *The American Lumberman*, and formed part of a letter from its Seattle correspondent:

When J. S. Bennett, of the Jay S. Bennett Lumber Company, returned from the East last week he brought with him a shingle bearing the union label. The securing of the shingle furnishes an object lesson to millmen as to what would be the result of unionizing the mills and placing control of all plants in the hand of the union. Exhibiting the shingle, Mr. Bennett said:

"This shingle, which is what is known as a bastard of the worst kind, was the wrapper on one bundle of a shipment sent out by us to Newark, Ohio, March 29. As you see, it has the union brand I. S. W. U. stamped on it. It came from one of our contract mills, which had signed the contract to allow the union to operate the mill and brand all shingles with its label. I happened to be

in Newark and saw a man putting this shingle on a house. I inquired regarding it and found it was from our shipment. I also found that the same shipment contained many of the same kind, which are wholly worthless. I promptly made a reduction on the car, on account of the quality of these unionized shingles. This shingle, and most of the others found, is a featherweight. It is a regular clear shingle, but in every way a bastard. It should never have passed the knot Sawyer, and if it did, the packer should have thrown it away. Under the open shop plan, where the manufacturer controls the manufacture of his product, this or any other shingles would not have gone out.

Immediately on my return home I canceled my contract with this union mill. I find I am having trouble with every shipment of union label branded shingles I made from this contract mill."

Commenting on the foregoing, *The Industrial World* says:

The union label does not represent skill, superior workmanship, or merit in any degree in any trade or business wherein it is used, but is simply a badge of discrimination and a weapon of organized labor with which they seek to force employers, employees, and the public to bow to their arbitrary rule and monopolistic dictation.

The American nation was founded on fair play and a square deal to everyone who became its citizen, and a device that is used as a symbol of monopoly or as a weapon to aid in creating a monopoly should not be sanctioned by the public for a single moment.

It does not matter where arbitrary monopoly appears, whether in capital or labor, the principle is essentially un-American and vicious; nor does it cut the slightest figure as to the methods that may be adopted to create and maintain such a monopoly, wherever they appear, or under whatever guise they may assume, the public should crush them without hesitation or remorse.

The union label is a form of general boycott, intended to proscribe those who do not use it. It is the most dangerous of all the weapons that the labor trust has invented.

THE GUGGENHEIMS IN POETRY.—There was a time when the Rothschilds represented the big purchasing element in mining business; then came Whitaker Wright, Hooley, and other promoters, including first-class financial houses like the Exploration Co. But other times, other people. Just now Schwab and the Guggenheims—the latter preferred—are filling the imagination of the prospective seller of mines. These remarks will introduce the following verses that come to us from Alaska:

If you've got a claim on Swede creek, or Montana or Moosehide,
Which to plant on some poor sucker for many years you've tried,
Don't rush away to Europe, or other foreign climes—
Just stay right here in Dawson and approach the Guggenheims.

If you've got the hard rock fever and have staked upon the Dome,
Or own a claim upon the lead that runs from here to Nome,
Don't let 'em lapse, whate'er you do, but hustle round betimes,
And unload your proposition on the wealthy Guggenheims.

Perhaps of all the placers you have got the very cream,
Or a dredging proposition, or some other wild-cat scheme—
Don't take too many chances in these fluctuating times,
But get a sudden move on, and see the Guggenheims.

Whether the gentlemen who congregate at 71 Broadway, New York, are easy, we do not know. We suspected otherwise. But why disillusion the enthusiast at Dawson?

THE interests of science and of industry are identical; science cannot make a step forward without, sooner or later, opening up new channels for industry; and, on the other hand, every advance of industry facilitates these experimental investigations, upon which the growth of science depends.

Another Cornish Flotation.—Mining Costs on the Rand as Compared to Cornwall.—Death of Richard Tangye.—Discoveries in the Mysore.—West Australian Dividends.—Concentration at Broken Hill.—The Deep Leads in Victoria.—Mining in Sumatra.—Returns From Mexican Mines.

The latest event in Cornish mining is the formation of Wheal Kitty & Penhalls United, Ltd. The capital is £35,000 in shares of 10s. each, of which £1,000 goes to the vendor company in cash, with £12,000 in fully paid shares, that company giving a guarantee for the subscription of £10,000 toward the working capital. The directors are Messrs. J. H. Collins, Arthur Pearce Jenkin, and John Vivian. The property, which is in the St. Agnes district, comprises Wheal Kitty, about 200 acres in extent, traversed, it is said, by at least five known lodes, and Penhalls, which adjoins, nearly as large. The prospectus states that the directors are advised that the lodes may be opened out so as to make large and profitable returns. Both mines have been worked at intervals for a long time, but no records are available as to the early workings. Since 1853, Wheal Kitty has returned 8,393 tons of black tin ore for £508,683, working on a small scale with old-fashioned machinery. Penhalls, from 1860 to 1884, yielded 3,592 tons of tin ore for £212,083. The new capital will be employed to deepen and equip the main shaft, and to open out the various lodes for an increased output, and to provide machinery as may be required, including rock-drilling plant. Another property is being taken in hand by Mr. J. H. Collins for future flotation as a limited company; it is the Tregrahan mine in the St. Austell district, where also the Wheal Eliza group is attracting attention for operation on the same lines in the near future.

A comparison made by a Cornish press correspondent shows that, while working costs on the Rand during a recent period reached 22s. 3d. per ton of ore-stuff milled, at least one Cornish mine was working at a cost of 13s. 8d. per ton of ore-stuff milled and magnetically treated. Even Dolcoath, working over half a mile vertical from surface, and after paying lords' dues and all development, was able to keep its working costs during the first half of this year to £1 1s. 10d. per ton. Cornish lode-values are, roughly speaking, 2% black tin, or, say £2 per ton of ore-stuff raised, plus copper, arsenic, wolfram, and other by-products.

A notable Cornishman, bearing a name familiar to mining men the world over, has just passed away. From the numerous obituary notices it may be gathered that from the humblest origin, Sir Richard Tangye worked his way to a position of great affluence and of high standing in the world of engineering. His brothers were partners in the wonderful growth of the enterprise, from a back shop and one 'hand' to a block of buildings covering 20 acres, and giving employment to some 2,500 workmen, but it must be laid to the credit of Sir Richard that he it was who saw the possibilities for their mechanical and engineering skill in Birmingham and induced his brothers to throw in their lot with him. The story is re-told, of how Brunel, the famous engineer, being in need of some powerful appliances to aid in launching the Great Eastern, went to the small Birmingham workshop. The result was that Tangye Brothers supplied the hydraulic lifting-jacks of their own invention, which set the vessel afloat, and enabled Sir Richard in later days to declare: "We launched the Great Eastern and the Great Eastern launched us."

Discoveries of considerable importance are reported in the three bottom levels of the Mysore mine at depths of 2,060, 1,960, and 1,860 ft. driven south from McTaggart's shaft. At these points the lode varies from 1½ to 2½ ft., with assays of 12 dwt., 1 oz. 2 dwt., and 2 oz. 18 dwt. per ton. It is considered to be too early yet to form conclusions as to the dimensions of the new shoot, but on September 6 they had already driven 40 ft. in reef worth over 2 oz. per ton at the deepest point—the 2,060-ft. level. These discoveries in the southernmost part of the mine are said to clearly demonstrate the fact that the lode in going south is repeatedly being folded to the west.

The West Australian dividends declared during the past quarter are once again over half a million sterling, amounting to £504,161, which compares with £548,575 for the second quarter of the year, and £419,000 for the first quarter. The Oroya-Brownhill heads the list for the past quarter with £90,000, Golden Horseshoe being second with £75,000, and Great Boulder third with £65,625, while Great Fingall, with £62,500, is not far behind.

Regarding the Broken Hill district, information is to hand from the Zinc Corporation as to the results of the investigation work in the treatment of the company's tailing by Mr. A. L. Queneau and staff. A long series of experiments have been made, and the final test-run of 1,300 tons of tailing showed a recovery of 81% zinc, 55% lead, and 55% silver. There were 348 tons of concentrates produced from the 1,300 tons of tailing, having a value of 44% zinc, 8% lead, and 8 oz. silver. A parcel of these concentrates was further treated, and it has been demonstrated that the concentrates could be separated into a lead concentrate and a zinc concentrate, the former having a value of about 45% lead, 10% zinc, and 20 oz. silver per ton, the leady concentrate embracing about 12% of the whole, and it can be still further treated to improve the lead content. The zinky concentrate, containing 88% of the entire concentrates, has an average value of 50% zinc, 4½% lead, and 8 oz. silver per ton. The directors are advised that the management considers it possible to improve these results when the plant has been fully organized, and Mr. Queneau states that he can guarantee an extraction of 85% zinc, 60% lead, and 60% silver. These results are deemed highly satisfactory and show that systematic working will be very profitable. The No. 2 plant on the British Broken Hill Proprietary mine is now in process of alteration and expansion, in order to provide sufficient capacity to treat the whole of the current output of that mine. This plant is expected to be in full operation by December 1. The large No. 1 plant, which is being constructed to treat the tailing from the Block 14, South, and Block 10 mines, is making satisfactory progress.

Cabled advices received from the general managers of Loddon Valley Goldfields state that they have successfully extended the main escape drift at the 410-ft. level into the gravel beds lying above the wash. This drift is 44 ft. above the main drift, and the gravels which have been entered are therefore 15 to 20 ft. above the wash. This indicates that the water has now been drained to below this level, and that there will be no difficulty in entering the wash itself from the main workings as soon as the precautionary work required by the Government has been completed. This work will require some weeks to carry out. The point entered is on the western side of the ancient valley, and is some 300 to 500 ft. from the auriferous channel.

Interest in Mexican mines continues to be fairly well maintained on the market. According to the September return from El Oro, No. 1 mill ran 27 days; the No. 2 mill ran 28 days, and together crushed 20,277 tons of ore, producing \$184,710; less working expenses \$90,306,

development expenses \$8,879, leaving \$85,525, profit from the railway \$5,443; total \$90,968 U. S. The sum of \$475 was expended during the month on permanent improvements. The Dolores return for August is only just to hand. The profit for the month is \$10,764 from 1,111 tons treated, the total receipts being \$33,784. The report states that indications are that from \$15,000 to \$20,000 additional profit is at present locked up in the cyanide plant which will be released in the final clean-up. Owing to a break on the line-shaft driving the battery, the August output was materially curtailed. Late telegrams show that the mill is again in regular operation. Rumors which have been rife concerning Dolores have received confirmation from a circular issued this week by the English company. The directors inform the shareholders that they have received from the board of Dolores Mines Co. a copy of Mr. John B. Farish's report on his visit to the mine in June and July last. The directors of the American company advise that their agreement with Messrs. Farish and McCarty has been terminated, and that they have appointed Mr. George A. Schroter as consulting engineer. They also state that, in view of the fact that considerable expenditure for additional equipment, buildings, additions to the mill, etc., will shortly be necessary at the mine, and in view of the desirability of providing for the existing indebtedness and for an ample working capital, they are of the opinion that the stock of the American company should be increased from 330,000 shares of \$5 each, to 400,000 shares of \$5 each. The additional new shares are to be offered at par to the English company, and this arrangement necessitates a corresponding increase of 70,000 shares in the capital of the English company; 66,000 of such new shares will be offered to the members of this company at \$5 per share, and it is intended to leave the remaining 4,000 shares unissued at present.

Melbourne, Australia.

Coal Miners Strike.—The Dog Watch.—Labor Unrest at Broken Hill.—Gold Stealing in Western Australia.—Evidence Before the Royal Commission.—Serious Allegations.

The air is full of talk about strikes. The first of these in importance is the one threatened in the Newcastle coalfield. To understand the dispute one has to go back a little. There has been a simmering of discontent in the district for a very long time. The last general strike took place on the broad question of an increase in the hewing rate. By an old agreement the owners consented to advance 4d. per ton on the hewing rate for each shilling per ton advance in the selling price of coal with a then minimum rate of 2s. 10d. per ton. A strike occurred on the question whether the rate should be jumped to 3s. 6d. per ton and the men after being out of work for two months capitulated on a hewing rate of 2s. 11d. as against 3s., which had been previously paid to them. Since then there has been an Arbitration Act to prevent strikes, but the miners have in this instance ignored that statute and taken the law into their own hands. What they ask for is the abolition of the night or 'dog watch' shift. The agitators are in the Maitland district, but their cause has been endorsed by the Newcastle miners with whose Union the Maitland miners' lodge is affiliated. The miners' claim is that the climate is so trying that they cannot sleep in the daytime after the 'dog watch,' and that there is no real need for the third shift, from 12 P. M. to 8 A. M. They point out further that the cessation of work for the shift will ensure the better ventilation of the working places, thus making them healthier and permitting of a greater output during the working time. Then there is a proposal that the hewing rate

shall be raised 8d. per ton. At present the selling price of coal is 8s. per ton, but the hewing rate is on the basis of a selling price of 9s. per ton; therefore, to increase the hewing rate 8d. per ton means raising the selling price to 11s. per ton. The owners offer to abolish the 'dog watch' from the end of the year except in the case of two pits at Maitland, and to raise the selling rate to 10s., thus guaranteeing an increase of 4d. per ton in the hewing rate. The real fight, however, is over the 'dog watch,' and it is not clear at the moment of writing whether a strike is to take place or not. The output of the Newcastle collieries is about 4,000,000 tons per annum and any disruption of the trade means a serious loss to every industry in the commonwealth. No wonder, therefore, that the strike is in everyone's mouth. The owners are fighting bravely and they have the public sympathy, without which no labor movement can succeed.

Another small cloud is the threat of a demand for higher wages from the silver-lead miners of the Barrier. These some time back applied to the Arbitration Court for an increase, but were denied any advance. That was asked mainly because lead was then worth only between £11 and £12 per ton, and the Broken Hill Proprietary Co. was only making 3s. 3d. profit per ton of crude. Last half year, however, saw that profit raised to over 20s. per ton, owing to the average price obtained for lead during the term being nearly £15. Now lead is up to £18 10s., and the company is obtaining a large additional revenue from its zinc residues. All the other companies show equally improved balance sheets. The mining population has in no sense shared in the more prosperous state of the industry. It must be confessed that there is a good deal of sympathy with them. At the present time the average earnings of miners are about 11s. per shift of eight hours. Living is expensive at Broken Hill and the climate very trying, especially in the summer time. The whole subject at present rests in the hands of the Proprietary employees who have held meetings to discuss the subject, but have postponed any decision for a fortnight. Should a coal strike come, the miners may be thrown idle, and then the movement may fizzle out, especially if the period of enforced idleness extends over a lengthened period.

Some remarkable evidence has been given in Western Australia before a Royal Commission appointed to inquire into the gold stealing evil. The investigation was the outcome of an interview with Mr. J. E. Scantlebury, a London journalist, who asserted that he had been told by a reliable State official that gold to the value of £1,000,000 was stolen annually from the Kalgoorlie mines. This statement, though obviously an exaggeration, was still sufficiently damaging to attract wide-spread attention, the result being the appointment of the Royal Commission alluded to. Evidence given before it has been sufficiently startling to move an inert police force into action. It has been shown that gold has been bought on a large scale, and that in some instances no proper records were kept in contravention of the law on the subject. Several buyers have been haled before the courts, and have been called upon to explain how they came in possession of the gold. Allegations have been made that those interested in illicit gold dealing erect retorts and assay plants; sometimes almost in their drawing-rooms; in other instances, hidden away in the bush or in discreetly constructed outhouses. Cases have been known where mines have been worked ostensibly for gold, but really to provide a small quantity of stone to mix with the rich ore stolen from the mines. It can thus be seen that the business was conducted on a large scale and with such system as to prove that it must have been a profitable venture. There have been recriminations. The police have been charged with neglect to enforce the law, and they in turn have accused the mine manage-

ments of laxity in supervision. The truth would appear to be somewhere midway.

Calumet, Michigan.

Good Progress at the Centennial.—Bottom Workings in Good Ore.

Another Shaft on the Allouez.—Calumet & Hecla Sinks No. 17

Shaft.—Water for the Michigan.—The Champion Dividend.—

Re-opening the Cliff Mine.

Excellent ore is being exposed by the lower levels of the Centennial mine. It is expected that the Centennial's output this month will be the largest in the history of the property. For more than a year the mine has been adding to its reserves at the rate of over 10,000 ft. per year. Since the third stamp went into commission at the Centennial's Grosse Point mill, the mine has increased its shipments to 800 tons per day, and there has been a corresponding increase in the copper production. The laying of the skip-roads in No. 2 shaft to the 18th level was completed a short time ago and the tracks are now being ballasted. Work has started on the erection

overburden on the 80° dip of the shaft is 60 ft. deep and it was penetrated in exactly four weeks—a creditable record. The timbering is done in six-foot sets. The ground is dry and firm. Henceforth, for the next two years, sinking will progress at No. 2 through the barren rock necessary to reach the lode, which is 2,200 ft. distant. For the present efforts are being devoted primarily to the addition of reserves; drift-stopps are being opened so that the development work is furnishing a good volume of production. A 60-drill Nordberg compressor is to be erected at No. 1 shaft.

Preparations were begun by the Calumet & Hecla this week for the resumption of work in No. 17 shaft on the Osceola amygdaloid. This is the only idle shaft remaining on that branch of the property and is the most northerly opening. Work was discontinued there about five years ago, when some of the other shafts were closed down. Since then the other shafts have been placed in commission. No. 17 is down only 100 ft. or thereabout, and is not provided with a heavy equipment like that at the other Osceola amygdaloid shafts. It has a temporary

of the permanent Sullivan hoisting-engine for this shaft, the sandstone engine-house having been finished a short time ago. As soon as the hoisting-engine at No. 2 goes into commission, track-laying will be resumed below the 18th level and completed to the 27th, to which depth the shaft is opened to the full size of two compartments. The new Nordberg 60-drill compressor is expected this week. Its erection should be completed early next month, when the 25 drills now at work will be increased to 35, production and development work being enlarged correspondingly. The showing of rich ground in the 27th level drift south of No. 1 shaft continues. Rich ground was penetrated in that drift three weeks ago. This ground is beneath a rich portion of the 26th level and probably it is the same shoot. At the 30th level—the lowest point to which lateral development work is under way—the ore is rich. As soon as the new compressor is installed the Centennial will put 10 more drills to work, which will permit the opening of extensive reserves in anticipation of a further increase in production. Mr. H. F. Fay, the president of the company, admitted on his recent visit to the mine that a fourth stamp would probably be added next year to the Grosse Point mill. This will close the Centennial's heavy construction account.

The No. 2 shaft of the Allouez mine has reached the lode and sinking in bedrock was started this week. The

shaft-house and hoisting engine, which are adequate for some time to come, however. The Calumet & Hecla a few years ago extended its railway tracks to a point 1,500 ft. north of No. 17 to a location known as No. 18. It was intended to sink a shaft there, a short distance from the Centennial's boundary line, but the plan was abandoned. With the resumption of work at No. 17, the Calumet & Hecla now has five active openings on the Osceola lode, all of which are a source of large production. The improvements at the Lake Linden stamp-mills permit a greatly increased tonnage to be treated, and much of the increase is coming from the Osceola and Kearsarge workings.—Sinking is likely to be resumed at the Old Colony soon. The drift which encountered a good showing of copper about two months ago at a depth of 700 ft. has continued in the same character of ground since then. It is believed that the lode is the same as that operated by the Isle Royale.

Plans are under consideration by the Michigan company for a tunnel to be driven under Lake Superior at Keweenaw Bay to provide water for the new stamp-mill that is being erected there. A shaft will be sunk to a depth of 70 ft., from which a tunnel will be driven 1,200 ft. under the lake. At the extreme end an opening will be made through the 30 ft. of lake-bottom, and the water will enter through this opening. Work is now progressing rapidly on the foundations for the Michigan mill.—

The old shaft on the Hancock will be pumped dry by the end of the month. Drilling machines will be placed underground just as soon after that as possible and stopping begun. The Hancock produced 5,000,000 lb. copper during its former period of activity.—Hereafter work should progress much faster at the Keweenaw Copper Co.'s Medora mine, in Keweenaw county, as the steam plant went into commission this week. Previous to this time the Keweenaw did all of its drilling with hammer and drill, while the hoisting was done with a donkey engine. The new engine is good for a depth of 1,500 ft. The air-compressor is capable of operating 12 drills, and this equipment will carry the Medora's work through the exploratory period.

Work on the new office buildings of the Champion Copper Co. is practically completed. The Champion has declared a dividend of one dollar per share, which makes its total payments this year \$800,000, or \$8 per share. Provided dividends of \$1 each are declared in November and December, its payments this year will be the same as last, namely, \$1,000,000, one-half of which goes to the St. Mary's Mineral Land Co. and the other half to the Copper Range Consolidated Co.—Diamond-drill work on the Cliff property, owned by the Tamarack, continues. Unwatering of one of the old shafts, sunk in the early days to operate a fissure vein, has started. Much repair work on surface was needed to make the opening safe. The shaft cut many amygdaloid belts, which received no attention, and it is now proposed to investigate these lodes. Among the formations to be tested will probably be the Medora and Montreal amygdaloid, which are being developed on the Keweenaw and Calumet & Hecla lands a few miles eastward.

Butte, Montana.

The Goldsmith Flotation.—Butte Money in the Coeur d'Alene.—The Butte Copper Exploration Co.—Output of the Original and West Stewart.—Clark's Operations.—Production of Boston & Montana and Anaconda.

The Goldsmith Mining Co., with a capital stock of \$3,000,000, divided into 300,000 shares, has been organized in Butte by those in control of the East Butte. The new company has taken over the Goldsmith mine, an old silver producer, which has been yielding copper lately at a depth of 400 ft.; also the Millside, Silver Safe, and the Tiger Lilly, four full claims lying west of the Alice mines of the Butte Coalition Co. The Goldsmith has been productive for several years; at a depth of 400 ft. the ore assays as high as 3½% copper. The directors of the new company are: C. W. Ellingwood, former owner of the mine, who will remain as general manager; Henry Mueller, Alexander Johnstone, Patrick Wall, and Charles R. Leonard. The Goldsmith is on the Rainbow vein, and, like the Alice and other mines on that famous lode, is expected to turn rapidly into copper with further depth. James W. Neill, who examined the East Butte and the United States mines, and upon whose reports those properties were organized into big companies, made the examination of the Goldsmith properties and reported favorably on them. Mr. Ellingwood is still working the Goldsmith and is employing 50 men. The ore is being shipped to the East Helena smelter. The stock of the new company will be underwritten at \$5 per share, and 200,000 shares will be issued. Half that amount was underwritten in Butte on the day the company's organization was completed, the Clark interests taking big blocks of it.

A strong effort is being made to make Butte the headquarters for Coeur d'Alene mining stocks, because Butte men have invested largely in the mines of that district.

A great deal of Butte money has gone into the Snowstorm and Snowshoe mines, and several mining experts, representing large interests, have thoroughly examined these two properties. The Snowstorm is producing 250 tons of ore daily that runs about 6% copper, and it is claimed that more than 1,000,000 tons of the ore are blocked out. Rapid progress is being made in the Snowshoe in driving for the Snowstorm vein.

The shaft of the Butte Copper Exploration Co. has reached a depth of 1,000 ft., and the company is now engaged in sinking a sump and station, which will take about two weeks. On the completion of this work a cross-cut will be run north to the veins. Although the company has encountered some spots of ore in the shaft, there has been found nothing to justify any special booming of the enterprise. The property is, however, so located that great expectations are warranted. The company owns eight mining claims in one group, comprising 93½ acres. It owns the Cora placer, a strip of ground on the Greendale placer owned by the Butte & London Co.; it owns the Golden Chief, East Golden Chief, Anvil Fraction, Grand Prize, Six O'Clock, Baltimore Fraction, and the Maryland lode claims. There are a number of known veins in this ground. At the west end of the Golden Chief there is a shaft 125 ft. deep that was put down about 18 years ago; this shaft shows a good vein that carries 3½% copper and pieces of copper glance, but ore of that grade was not considered of much value at the time the work was done. On the same claim is another vein with a wide cropping. The company has 3,000 ft. on the two veins. On the Anvil Fraction there is a vein that strikes northwest-southeast, and is 30 to 40 ft. wide. On the Grand Prize there is a vein about 30 ft. wide on the surface. The Six O'Clock is the main vein and it is 90 ft. wide. The same vein also runs through the Grand Prize, as is shown by cross-cuts. Samples have assayed as high as 6% copper. Rapid progress has been made in sinking the shaft and equally good speed will be made in running the cross-cut. It is expected that one of the veins will be cut about the middle of December.

W. A. Clark's two mines, the West Stewart and the Original, are yielding almost all the ore that is treated by the Butte Reduction Works. The production varies greatly, ranging from 700 to 1,100 tons per day for both mines, of which about two-thirds goes through the concentrator, and the rest is first-class ore, ready for treatment in the smelter. The Original, which produces rather more than half of the output of the two mines, lies between the Gagnon and the Parrot, both belonging to the Amalgamated. But the strong vein in the Original seems to have held better ore all the way down than in the adjoining mines. The Original has reached the 2,000-ft. level, and stoping is being done there. The ore is low grade, a decrease in value being noticed below the 1,600-ft. level, as has been the case in the Amalgamated mines to a certain extent. Nevertheless, there is ore enough in reserve so that the company does not see fit to sink at present, in order to explore deeper, where the Anaconda has found large orebodies. The Original vein is 50 ft. wide on the 2,000-ft. level. The West Stewart is down 1,900 ft., and a cross-cut is being run to the vein on that level. It shows the same lessening in value of the ore below the 1,600 level as does the Original. The only important development work being done by Clark is the sinking of the shaft on the Elm Orlu claim, near the Butte & Superior group. There is ore enough blocked out in the two productive mines to keep the Butte Reduction Works busy for some years, but Clark appears to realize that the future of the district is dependent on the territory outside the present limits of the copper zone, and the active working of the Elm Orlu is pretty sure to

give a large reserve of high-grade copper ore, while there is every reason to believe, from the experience in neighboring mines, that the upper levels will yield silver.

Work has been resumed on the West Colusa mine of the Boston & Montana Co., and about 400 tons of ore will be added to the daily output of that company. The Boston & Montana is now shipping about 3,400 tons of ore daily, and 1,500 tons of it comes from the Mountain View. The ore assays about 5% copper. — The Anaconda Co. is shipping about 3,600 tons of ore daily from its mines, and it assays from 3½ to 4% copper.

Toronto, Canada.

Prospecting the Gillies Limit.—Demand for Reports of Ore Shipments

at Cobalt.—Further Flotations.—Wonderful Ore in the Nipissing.

—The Laurentian Ships Specimen Ore.—Mineral Discoveries in the Laurentian Range.

E. T. Corkill, Provincial Inspector of Mines, returned this week from the Gillies Limit, Cobalt district, where he was for some time in charge of development work. He reports that good progress is being made in sinking the 75-ft. shaft, which it is expected will be finished about December 1, when the value of the 6-in. vein will be definitely ascertained. Systematic trenching has disclosed a number of other veins, carrying silver in paying quantity, such as if owned by private individuals would bring large figures in the market. — An agitation is being started for the publication of regular official reports of shipments of ore from Cobalt. At present all that is required from mine-owners in the way of information is a quarterly return to the Bureau of Mines, and this is not available to the public until some time after the returns are made. No details of an official character have been given for months. It is proposed that a weekly report of the ore shipments over the Temiskaming & Northern Ontario Railway shall be given for publication. Frank Cochrane, Minister of Lands & Mines, has expressed himself favorably on the proposal.

Large financial deals in Cobalt properties are reported almost daily. The McLeod-Glendenning mine, formerly known as the Hanson mine, in the district between Cross and Kerr lakes, has been sold to McCornick Bros., of New York and Salt Lake City, for \$600,000. The sellers paid \$400,000 for the property in May last. It comprises one vein that has been opened to a depth of about 30 ft., and several as yet undeveloped. The Green-Meehan mine, two miles north of Cobalt, in Bucke township, has been bought by a syndicate of New York, Toronto, and Ottawa capitalists for \$250,000. Ore valued at \$30,000 was recently taken out in three days with pick and shovel. W. Y. Soper, of Ottawa, is a prominent member of the purchasing syndicate. — Prof. W. E. Hidden, mineralogical expert for the Nipissing Mines Co., states that the company on October 19 shipped \$60,000 worth of bonanza ore, and has now 33 bbl. ready for shipment. About 1,800 lb. are put in each barrel. The shipments for September brought about \$250,000, and for October from vein No. 49 alone they will double that figure. A pile of picked ore at the mine about 10 ft. diam. and 4 ft. high, was valued by the Professor at \$100,000. Two cars of high-grade ore were shipped to the smelter from the Silver Queen on October 24, and another car will be sent within a week. The Nancy Helen Mines, Ltd., has been organized, with W. R. Smyth as president, and William Black, secretary and treasurer. The properties are situated in the town of Cobalt, adjoining the Buffalo, where a shaft has been sunk 60 ft., and two carloads of ore are ready for the smelter. — J. L. Englehart has been appointed chairman of the

Temiskaming & Northern Ontario Railway Commission.

Anthony Blum, principal owner of the Laurentian gold mine, in the Manitou district, has forwarded to Boston 300 lb. of ore to be placed on exhibition in that city. It is estimated that from three-fourths to four-fifths of the ore is gold. Some samples showed the rock almost hidden by the gold with which it was encrusted. — At the Redeemer gold mine, in the Dryden mineral belt (R. W. Eames, superintendent), a cross-cut is being run from the present shaft to a 75-ft. dike, the distance to which is 350 ft., of which 125 ft. have been cut. — L. O. Armstrong, colonization agent of the Canadian Pacific Railway, reports two valuable discoveries in the Laurentian range within 100 miles of Montreal. Extensive deposits of uranium and pitchblende have been found to occur in association with the mica mines of that region. A large deposit of graphite has been found as an outcrop, scattered so loosely that a couple of men can pick up two tons per day without blasting. The graphite is about three miles from the railway.

Salt Lake City, Utah.

New Concentrators Under Construction.—Plant for the Nevada-Douglas Copper Mines.—Heinze's Purchases.—Dividends.—Local Business.

Notwithstanding the fact that labor has been scarce and progress has been considerably handicapped, the new mill of the Utah Copper Co., at Garfield, 15 miles west of Salt Lake, will be completed on schedule time. It will be ready for commission early next year, and will, when the second unit is finished, handle an output of 6,000 tons of ore per day. The Boston Consolidated Co. is also pushing construction on its plant, which is to handle 5,000 tons per day, and if everything goes well it will be ready for business in April next. The Markham Gulch Milling Co. has let the last contract for material and equipment, and the plant to be erected in lower Bingham will supply a place for the treatment of 200 tons of ore daily from the Utah Apex and Utah Development mines, at Bingham.

Walter C. Orem, the manager of the Nevada-Douglas Copper Co., has closed a contract for a large equipment of machinery, which has been ordered shipped to Yerington, Nev., without delay. This company is executing plans mapped out some time ago to operate its property upon a large scale, and late reports indicate that it is likely to develop into one of the big copper mines of the West. Some high copper assays have been obtained, but the great bulk of the ore opened is low grade and will pay handsomely only by handling a large tonnage. The average of the Yerington ore, however, assays better than that of the mines of either Bingham or Ely. — The management of the Newhouse Mines & Smelters Corporation, operating the Cactus mine, in Beaver county, has closed a contract for the immediate construction of forty cottages for the accommodation of employees.

Although nothing has been given out officially, there is little reason to doubt that the Ohio Copper Co.'s mine, at Bingham, has passed into the control of F. Augustus Heinze. The option has been pending for some time. Mr. Heinze is also a controlling factor in the development and equipment of the Gold Hill mine, in the Clifton section of the Deep Creek district, which recently formed the basis for the organization of the Western Utah Copper Co. — Some rich phosphate deposits have been opened in the extreme northeastern part of the State of Utah and extending into Idaho and Wyoming. The ground has been acquired by the Union Phosphate and San Francisco Chemical companies.

Among the Utah mines that paid dividends and the amount of each were: Silver King, Park City, \$50,000; Utah, Fish Springs, \$3,000; Sacramento, Mercur, \$5,000;

and the following from the Tintic district: Beck Tunnel Con., \$30,000; Mammoth, \$20,000; Grand Central, \$15,000; Victoria, \$10,000; Carisa, \$5,000.—The ore and bullion settlements in Salt Lake last week amounted to \$924,000; during the same period \$161,709 represented the value of 293,593 shares of stocks sold on the floor of the Salt Lake Stock & Mining Exchange.

Leadville, Colorado.

The Yak Tunnel.—New Orebody in the Penrose.—Prospecting in Iowa Gulch.—Encouraging Find on Ball Mountain.—Good News From New Monarch and Weldon.—Great Activity on Breece Hill.

Early snows have hindered mining operations in the outlying districts and practically stopped all surface prospecting.—The Yak Tunnel Co. is quietly but persistently extending the net-work of laterals from the great bore. Companies which own property in the vicinity of this adit realize its importance as a means of developing their properties economically, and, as a result, the laterals are being extended from numerous points into both Iron and Breece hills. Many mines which have laid idle for years will become profitable as a result of these advantages.

By means of drifts and drillings from the Penrose workings north of Seventh street, the expectations of the management—that the great ore-shoot below the parting quartzite in the Coronado continues to the west—have been confirmed. A sulphide body of undetermined extent has been found west of the new fault, the latter displacing the orebody about 250 ft. The fault has a northeasterly direction and passes a short distance north of the Coronado shaft. The newly located orebody is probably the extension of the Coronado shoot now being worked to the east of the fault. Raises in the same territory show large bodies of first-contact iron familiar in the early down-town operations.

Judge A. T. Gunnell, of Colorado Springs, has given an option on an undivided three-fifths interest in the Lucy L. mine at Camp Harrington for \$25,000. Judge Gunnell has owned this property for many years, but of late no work has been done on it. The new management contemplates adding immediately an efficient hoisting plant, along with other machinery required to put the mine on its former productive basis. It is reported by the manager that a large body of ore of a shipping grade will become available with the completion of the contemplated improvements.—From the lower workings of the Continental Chief, located in Iowa gulch, ore is being shipped to the extent of 50 tons per day. During the summer months a large amount of prospecting was done in Iowa gulch, and it is reasonable to predict that this locality will soon become one of the most important of the outlying districts.

A recent strike, probably the most important for the month, was made in the Thatcher on Ball mountain. A drift from the shaft broke into an orebody, of solid galena several feet thick. For some time past small shoots of galena ore had been encountered in the Thatcher during the progress of driving. This ore is unusually rich in silver, and although it is too early to predict its extent, the discovery of the new shoot will give increased importance to Ball mountain mines in the future. About 600 ft. distant from the above property is located the Sunday mine, which was formerly a heavy producer of this class of ore. Large areas of Ball mountain are seamed with small fissures carrying galena and such properties as the Leopard, Ontario, Tiger, Helena, and others show strong indications of valuable galena deposits.

The rich shoot opened up in the New Monarch two months ago still continues to furnish valuable ore, and in

addition there has been opened up to the west of the Winnie shaft, a large body of 6 to 9-oz. gold ore. It is worthy of note that the production of gold from the deeper workings of all properties has for months been on the increase.—Greater activity is noted among the Breece hill properties; such mines as Highland Chief, Gold Basin, Winnie, Big Six, Penn, and Bollard have been recently added to the old producers. The Triangle mine has experienced unusual difficulties in putting the 900-ft. shaft in order, as, in addition to the water, the shaft was filled with old timbers. This property will develop 24 acres of virgin ground in a favorable locality on Breece hill.—The Weldon property, situated near the Penrose, will resume operations within the next thirty days. Lessees have worked this mine for several years in a small way, but a complete overhauling will now be made.

Cripple Creek, Colorado.

Growing Use of Electric Power.—Several Dividends.—Successful Leasing Operations.—New Companies Organized.—The Snow-storm Hinders Work.—Prosperous Activity.

The Extra claim, owned by the Grace Gold Mining Co., on the south slope of Squaw Mtn., has been started up again. Lessees have taken over this property and are installing an electric hoist, their intention being to sink the shaft, which at present is 100 ft. deep. This property adjoins the Home Run and Santa Rita mines, on which so much development has been done of late under the direction of Sherman Bell, general manager.—The British American Mining Co., Ltd., operating the South Dante, on Bull hill, has declared its first dividend of 10% on a capitalization of \$10,000. Work has been in progress on this property for the last 18 months, various difficulties having been encountered at times, seriously hindering operations. Everything is now in good shape, there being several hundred tons of ore, which will average better than two ounces in gold, already broken in the stopes. This lease is one of the best in the district. It belongs to Becker & Travell, who also have a lease on the Christmas mine, on Bull hill, which has paid an initial dividend of 25%. This lease is also in good shape for producing a large tonnage of fair grade ore. The electric-driven Norwalk compressor is now in running order and five Ingersoll-Sergeant drills will at once be put to breaking ore. This eight-drill compressor was originally driven by steam, but the steam end has been disconnected and the air part geared to a 100-h.p. electric motor.

The Western Mining & Leasing Co. has been incorporated. It is capitalized for \$100,000 and is to operate in Teller county. The directors for the first year are George F. Fry, C. S. Buck, T. C. McDonald, H. M. Finney, and F. M. Woods.

The recent snowstorm has hindered mining operations, the railroad spurs to the various mines being blocked with snow. Hauling was also stopped for three days and several of the smaller properties are now suffering from surface water.—Ore is being shipped to the Anaconda cyanide mill from the Lexington mine on Gold hill. It is obtained from a large deposit of semi-oxidized material in the South Clara D. workings and is conveyed on a tramway to the mill, about 40 tons per day being handled. This mill is also treating ore from the Colorado Boss, situated about half a mile to the east.—The cross-cut on the 800-ft. level of the Cresson mine, on Bull hill, is advancing rapidly and it is hoped that the large orebody encountered above on the 600 and 700-ft. levels will soon be cut. This mine belongs to the Bull Hill Mining & Developing Co., Richard Roeloff being superintendent. A new 12-drill compressor is being installed, it is to be electrically driven, the motor being already on the ground. The output for October will approximate 1,600

tons.—The production of the Little Clara lease on the Work property is being maintained both in tonnage and value. Owing to the recent snow, the ore has accumulated in the bins and it is estimated that there is in the neighborhood of 800 tons on hand averaging between three and four ounces. Royalties to the amount of \$12,000 were paid to the Work Co. by the lessees during the month of September, representing an output of \$125,000 in value.

A discovery of ore has recently been made in the old Davenport shaft of the Doctor-Jack Pot Co., on Raven hill, by Smith & Altman. The vein was encountered in the lowest workings of the mine and 150 ft. deeper than any ore previously found in the mine, or in any other mine in that locality. It was cut 70 ft. south of the shaft and averages \$60 per ton.—Mineral hill, one of the comparatively barren spots of the district, has produced from the Laura Lee claim a shipment of 40 tons of ore, which ran a little better than \$20 per ton. This is the first shipment to be made from this locality for years and the event has caused the starting up of other propositions in the vicinity.—Large shipments are being made by the Western Investment Co. from its Stratton Estate leases, operating on the Orpha May, Sacramento, and Specimen claims. Austin T. Holman, formerly general manager of the Golden Cycle Co., is president of this company. Ten cars per week, on an average, are being shipped from these properties, the ore running between one and two ounces.

Articles of incorporation have been filed by the Pharmacist Leasing Co. to operate on the Pharmacist property on Bull hill. It is intended to sink the shaft, which is 600 ft. deep, another 300 ft. and to do other extensive development. The directors of this new company, for the first year, are Clarence Edsall, H. N. Todd, and John H. Hobbs, all of Colorado Springs, and interested in various mines in this district. D. W. Mason is superintending the work of this company.—The El Paso Gold Mining Co., on Beacon hill, is shipping about 2,250 tons per month on company account and from various leases. This is a good showing considering that some of the best ore is under water just at present. The Lambright lease, belonging on this property, ships 750 tons per month and the Lonaconing about 400, the El Paso mine itself contributing the remaining 1,100 tons.—A new orebody has been encountered in the Forest Queen mine on Iron-clad hill.

The discovery was made at a depth of 550 ft. and 200 ft. east of the shaft. The screenings from this orebody, which is said to be of fair dimensions, run over two ounces per ton, the coarse averaging a little over one ounce. About three cars per week are being shipped.—The Vindicator Consolidated Gold Mining Co. has declared the regular quarterly dividend of three cents per share, amounting to \$45,000. A report on the mine by the general manager, F. J. Campbell, has been sent to the stockholders, showing the profit for July, August, and September to be \$54,799. This is encouraging, considering that one-third the cost of operating was spent on development. New boiler-furnaces, permitting the use of lignite coal, have been installed at a cost of \$4,500, and it is expected that they will save approximately 25% of the former fuel cost. During the three months there were shipped on company account 6,299 tons of ore having a gross value of \$156,855, giving a gross value per ton of nearly \$25. On lessee's account 1,116 tons were shipped, the gross value being \$20,405 and the average \$18.28 per ton. Incidental receipts brought the total up to \$178,760. The operating costs were \$104,326, of which \$51,557 was for labor. Money paid to lessees and taxes makes a total expenditure of \$123,961.

Mining Summary.

ALASKA.

The latest and one of the most valuable discoveries made in the new northern copper camp, west of Whitehorse, is that by Byron N. White, of Spokane, Wash., on the Pueblo. He has uncovered on the Pueblo a body of ore 250 by 270 ft., and has sunk about 100 ft. and has not, as yet, found either wall. The ore is almost solid hematite, heavily impregnated with copper minerals. This whole body is practically shipping ore, and will average in the neighborhood of four per cent copper, with some gold. There are masses and streaks, however, of high-grade ore forming a large proportion of the orebody. Cuprite and copper glance occur in considerable quantities, with some native copper and bornite, chalcopyrite, and the carbonates are thickly disseminated throughout the ore, so that, with only rough hand sorting, high-grade shipments can be made. It is certainly an enormous surface showing. He is shipping 100 tons at present.

ARIZONA.

MOHAVE COUNTY.

At the Banner mines of the Arizona-Mexican M. & S. Co., at Stockton Hill, a body of ore four feet wide has been encountered. The ore is solid from wall to wall and carries ruby and native silver in quantity, besides running better than 40% lead.—The Gold Roads mine is yielding bullion at the rate of \$60,000 per month, but the output will be increased to \$80,000 as soon as electric power from the Kingman plant becomes available. The shaft has just reached the 700-ft. station. On the sixth level the main ore-shoot has been opened for a length of 700 ft. and is 10 ft. wide. The present output is 125 tons per day, and with electric power will be 200 tons per day with the same plant. The ore yields readily to amalgamation and cyaniding, and the saving is 91½ per cent.

YAVAPAI COUNTY.

(Special Correspondence).—The Chronicle mine, at Prescott, is exciting more than usual interest. From a depth of 25 to 65 ft. the shaft, and the series of cross-cuts run from it, have all been in ore that carries high-grade values in gold and copper, the extent of the orebody being yet undetermined. At 650-ft. a horse was encountered in the sinking of the shaft, and this continued for a distance of 10 ft., when the orebody again re-appeared on the west side of the shaft, giving better gold and copper assays than the body passed through nearer the surface. Work on the shaft is being pushed with energy and a new hoisting plant, recently purchased, will be installed as soon as delivered. When a depth of 100 ft. is reached, drifts will be run in both directions along the vein and a series of cross-cuts run through the ore. There are five claims in the group, all of which are to be developed as fast as practicable. The claims and mine are situated four miles from Prescott, immediately east of the wagon-road running to McCabe and in the vicinity of the Four Mile house, in a district which has been traversed by miners and prospectors since the first settlements in Prescott and Lynx creek in the early sixties.

Phoenix, October 29.

CALIFORNIA

CALAVERAS COUNTY.

The Zeila Co. has put in a flume from the tailing plant to a point down the creek about 400 ft. for the purpose of carrying off the debris.

FRESNO COUNTY.

John S. MacArthur has finished his examination of the Fresno Copper Co.'s property and has left for Glasgow. His report is not likely to be cheerful. There is a large body of pyrrhotite containing about 1.7% copper, but under present conditions this is not profitable. Herbert Lang is said to favor smelting operations with the aid of custom work on silicious material. When the new Guggenheim smelter at San Bruno, near San Francisco, is completed, the ore of this mine may become available.

(Special Correspondence).—Since the cleaning and re-timbering of the 200-ft. shaft of the North Star was finished, the north drift has been extended 70 ft. It is now 100 ft. long and almost its entire length is in good milling ore averaging eight feet in width. W. G. Phipps, the superintendent, reports that it is the intention to begin sinking again at an early date and continue until the shaft reaches 500 ft. Within a few days the work of repairing the 10-stamp mill will be begun. One month will be required to complete this, when crushing will be resumed. There is 800 tons of ore on the dump.—The machinery for the 100 stamp mill purchased by the United Mines Corporation, owner of the Grizzly, New Albany, Dead Horse, and Lady Washington mines, has arrived in Tuolumne and is being conveyed from this point by teams. Work of erecting the mill will begin at once, the grading being nearly completed. The ditch and flume which convey water from the North Fork of the Tuolumne river to the Grizzly mine, where the new mill will be placed, are being re-built. Twenty carloads of lumber have been delivered to a convenient point on the Hetch-Hetchy and Yosemite Valley railroad for this purpose, and a crew of 30 men is engaged in the work of reconstructing the conduit. A 300-h.p. two-cylinder air-compressor has been received and another of the same size and pattern has been ordered. Underground work is being vigorously prosecuted at the Grizzly. A new hoist will be put up at the New Albany, the mine unwatered and the shaft enlarged. In time the Lady Washington adit will be extended to the workings of the Dead Horse, which will be

tapped at a great depth. The four properties are excellently situated for such a project as the United Mines Corporation has under way—working them all virtually as one.—A 150-h.p. electric motor is being installed at the Eagle-Shawmut mine so that the property can be under partial operation during the shut-down period. Power will be obtained from the Standard Electric Co. and everything will be kept moving except the 100-stamp mill, which will stop crushing within a few days. During this period of semi-activity about 60 men will be employed.—The 10-stamp mill of the Don Pedro mine was destroyed by fire last week, the loss being about \$10,000, partially covered by insurance. The company intends to re-build at once. The mine employs 20 men and sinking and driving is in progress.

Tuolumne, Oct. 29.

COLORADO.

LAKE COUNTY.

After thoroughly testing the mineral bodies of the Ida-May group, and having blocked out sufficient ore to warrant the expenditure, the Sargent M. & M. Co. has purchased an amalgamating and concentrating plant at Granite, and will move it this week to Sayers Gulch.

SUMMIT COUNTY.

(Special Correspondence).—For five months three drilling machines have been constantly employed in prospecting and systematically testing the Swan river placers, the work being done under the supervision of Mr. Tuttle, a California mine operator, at a cost of about \$30,000. J. Parke Channing, of New York, then came out, and having made a thorough examination of the ground and the results of the drilling tests, sent in his report, on the strength of which the option (held by Ben. S. Revett) was lifted. It is proposed to work this ground with four dredges similar in construction to that which is now being worked by Mr. Ben. Revett in French gulch.—During the season's hydraulic operations on the Banner placer some rich gold float was encountered and the further work of stripping the ground disclosed good indications for vein mining. Col. Kingsbury has secured a lease of some of this ground from the owners of the placer property, and intends to run an adit into the hill from the foot of Iowa gulch to prospect for the lode from which this float has been washed.

The Reliance dredge is making big clean-ups, and the result of this year's operations is most satisfactory. If the good weather holds out, work will continue into the month of November.

The Jessie mill is kept going to its full capacity. The company is now employing 30 men and is making a substantial profit; the whole aspect of the enterprise is extremely good under the able management of James T. Hogan, who has as superintendent Charles F. Gilbert. A small shipment of ore has been sent to Denver to be tried by the Hendryx electro-cyanide method, as it is thought a closer saving can be made by cyaniding the tailing, which now carries from \$3 to \$4 per ton.—A. C. Howard, the manager of the Bay State, reports that indications are favorable to the striking of a large body of ore in his main tunnel.—S. S. Woodbury is again working the Brewery mine, which is situated near the Lincoln in American gulch. This property has a good record for past production and is expected soon to rank among the shippers of the district.—S. F. Stoughton, of Illinois, has secured the Fourth of July claim under bond and lease; he intends to work it and ship the ore to the Lenawee mill at Montezuma.—The Quandary Mountain Mining Co. has resumed operations and is now taking out ore. This is to be milled at the rate of 60 to 75 tons per day.

The Gold Dust has cross-cut the main vein in the workings below the winze from the lower tunnel. The lode is 12 ft. wide, 4 ft. of which is silver-lead ore of smelting grade while the remaining 8 ft. is suitable for concentration. The hoist and pump are run by electric power. James L. Callbreath, of Denver, is manager.

The Wellington mine is daily improving in value by adding to its large ore reserves. When the new 300-ton mill is erected, it will have ample material to treat for years to come.

Breckenridge, Oct. 29.

NEVADA.

LINCOLN COUNTY.

(Special Correspondence).—The directors of Le Roy Mining Co. met this week and decided to put in a steam-hoist. A 70-h.p. boiler will be installed and the head-frame is already being constructed. The shaft, which is down 265 ft., is being straightened. Assays have run as high as \$80 per ton on this property, but the main body of ore is averaging \$12 per ton and it is generally conceded to be a very good low-grade proposition.—The Quartette is using water from the Drake shaft in the mill on the main property. On the 800-ft. level the values are increasing as they drive. This mine, which has been a large dividend payer for the past few years, appears to have an inexhaustible body of ore blocked out.—At the new camp Thurman, William Holt and C. A. Thrull, Los Angeles capitalists, have secured ten claims located near a spring of water close to the original discovery. They will also start a townsite on their claims, developing some of them for mining properties. They will also work a claim in the Winner group, near Searchlight.

Part of Nevada.

On the original Thurman-Hamill strike, at ten feet, paying ore has been struck.—The cyanide plant on the Searchlight M. & M. Co.'s property, with a daily capacity of 100 tons, is completed and ready for operations. The two 70-h.p. boilers are in operation.—The Pompeii has ordered a large steam-pump in order to remove 40 ft. of water in the bottom of the main shaft. The present gasoline pump is too small for the work. The intention is to resume active mining as soon as the water is under control.—The Cyrus Noble Extension, which adjoins the Duplex and the Cyrus Noble, has ordered a hoist. They are down 190 ft., with good showings, improving steadily with depth.

Eldorado Canyon, 18 miles from here, is developing fast and all their supplies are hauled from Searchlight by team. They have plenty of water; this is an old camp lately revived with several new strikes.—The Gold Dyke Mining Co. has a vertical shaft 103 ft. deep and a 50-ft. cross-cut to the south. The same lead found on the Blossom and Pompeii is plainly traceable across this property. They cut a 20-ft. vein of ore which assays from \$15 to \$40 per ton. The company's officers state they will sink to the 500-ft. level whether water is encountered or not, and will also put in milling machinery.

Searchlight, Oct. 26.

NYE COUNTY.

The Belmont-Johnnie has started work by sinking a shaft on the White Car claim on a vein that lies very flat and has lime on the foot-wall. A tunnel is also being driven on the Wellington claim on a vein averaging five feet in width and assaying \$8. The Johnnie Consolidated is working two shifts in the main shaft from the 300-ft. level to surface; the north cross-cut on the 700 shows five feet of ore averaging \$20. On the 600-ft. level, the south cross-cut is in ten feet of ore, three and a half averaging better than \$100 and the

whole mass averaging \$35. In the north drift the formation is very flat and the full width of the vein has not yet been determined.—Two shifts are working in the Globe lower tunnel to reach a rich shoot exposed in an upper tunnel. A depth of 25 ft. from the surface has been attained.—The working shaft on the Golden Eagle claim of the Bullfrog-Johnnie is being re-timbered from surface to the 50-ft. level.—A shaft is being sunk on the Runaway Girl claim of the Pittsburgh-Johnnie on a vein running parallel with the Golden Eagle. It assays \$30 in gold and 20 oz. silver and about 50% lead.—Robert Browne's copper property, the Johnnie-Wonder, has a blanket vein, the foot-wall of which has not yet been cut. Assays show 35% copper and \$5 in gold.—The Minnie Mae lease No. 4 has been taken by S. R. Phail, of Rhyolite, who is extracting milling ore averaging about \$20.—The Sunshine mines have been sold by Robert Atkinson, of Los Angeles, to a Philadelphia syndicate, headed by C. F. Sessinger and R. J. Purcell. This property is in the copper belt, adjoining the Johnnie-Wonder.—The Red Chief and Grey Rooster claims have been bought by Taylor and Griffith, of Rhyolite.

WHITE PINE COUNTY.

The Nevada Con. Copper Co. and the Cumberland-Ely Copper Co. will jointly build a concentrating and smelting plant. It is proposed to organize a \$10,000,000 smelting

New Mexico.

company, in which the two copper companies will each own a half interest. The smelter will be of sufficient capacity to handle not only the Nevada Con. and the Cumberland-Ely ores, but it will treat ore for other mining companies in the Ely district. The joint interests have already acquired about eight square miles of watershed in the vicinity of McGill, about 20 miles from Ely, which will furnish a supply of water to treat at least 25,000 tons of ore without re-pumping, and in addition the precaution has been taken to acquire all the ranches in the territory which might suffer from the loss or pollution of the water, or damage from the smelter fumes, and by this means all future trouble from damage suits, such as have been a source of heavy expense in the Butte and Utah copper districts, has been obviated. Part of the plan includes the purchase by the Cumberland-Ely company of one-half interest in the Nevada Northern railway, running from Ely to Cobre, on the Southern Pacific line, now owned by the Nevada Con. Company.

NEW MEXICO.

OTERO COUNTY.

The Fleming-Fox Mining & Smelting Co. is doing development work upon an extensive scale in the Jicarilla district. W. G. Fleming, president of the company, visited the mines last week. A steam hoisting plant is on the way

to the mines from Chicago and will be erected on the new shaft of the copper property, which is down 50 feet.

DONA ANA COUNTY.

Another noteworthy strike is reported from the Torpedo at Organ. In unwatering a portion of the mine, a vein five feet wide of high-grade copper ore was uncovered. The strike was made in an old portion of the mine which had been worked under former owners, but the working had to be abandoned when the water drowned the mine. Recently the mine was sold and large pumps were erected which are rapidly unwatering the old workings. In these old workings were found steel drills, drilling hammers, the rails of a tramway, and other tools, showing that the workings were abandoned in haste when the water was struck.

TAOS COUNTY.

The Hawkeye group of mining claims, near Amizett, has been purchased by the San Cristobal Mining Co., which is working a group of mines on the South Fork of the Rio Hondo. There is a mill on the Hawkeye, and the group carries large quantities of copper of a good grade. Extensive development work is to be done this winter.

GRANT COUNTY.

The Burro Mountain Copper Co. has blocked out a large body of copper ore on the fourth level of the Sampson at Leopold; this is in addition to the large bodies of ore blocked out in the second and third levels.

OREGON.

BAKER COUNTY.

Last week T. S. Van Vleet, manager of the Gold Bug, closed a contract with W. H. Potter for the immediate erection of a mill on that property. The timbers are all on the ground and the assembling of the machinery is under way.

CROOK COUNTY.

The Gatewood Mining & Trading Co.'s mill on the Mayflower mine started crushing ore. The mill has five stamps, followed by machinery. The ore is a sulphide, high grade and soft so that 20 tons per diem goes through the mill. Previous test-runs have demonstrated the success of cyanidation.

BRITISH COLUMBIA.

A strike of importance has been made on the Cork mine near Kaslo, north of Spokane, Wash., a property owned by the Silver Star Mining Co., controlled by French capital. The new orebody lies near the hanging wall of what is known as the Cork lead, and was found on the 900-ft. level. The orebody is about four feet in width. The mineral texture is a very fine-grained galena, carrying scarcely any zinc. Assays yield 91 oz. silver, 72% lead, and 8½% manganese.

MEXICO.

The smelter of the Mazapil Copper Co., Ltd., which is being erected in Saltillo is rapidly nearing completion. Almost all the steel structures are up and much machinery has already been installed. Carloads of ore from the company's mines are arriving daily and are being dumped in the smelter grounds. The Mexican Gold Copper Co. is resuming work on the Utah mine. It has a well-defined vein 42 ft. between walls, which assays about 25% copper, \$7 gold, and 20 oz. silver per ton. The Tres Amigos Gold Mining Co. also has several good properties.—The Parral Power & Reduction Co.'s preliminary electric power plant near Parral is nearly finished. The double main transmission line, 5½ miles long from the plant to the mines at Minas Nuevas is nearing completion also.

Personal.

W. L. AUSTIN is at Clifton.

F. LYNWOOD GARRISON is at Kingman, Arizona.

F. F. SHARPLESS has returned to New York from Mexico.

C. M. FUELLER has returned to Denver from Weiser, Idaho.

CHARLES PRINGLE is at the Isidro mine, near Chihuahua, Mexico.

J. ALLEN VEATCH is examining mines at Round Mountain, Nevada.

M. C. STAFFORD is visiting San Francisco from Kingman, Arizona.

HUDSON H. NICHOLSON has returned to Chicago from Goldfield, Nevada.

FREDERICK ROESER is superintendent of the Globe smelter, at Denver.

EDWARD W. RALPH is investigating the new goldfields in western Nevada.

HENRY Z. OSBORNE has returned to Los Angeles from a trip to Tonopah and Goldfield.

FRANCIS V. DRAKE, now resident at Bishop, Cal., has been on a visit to San Francisco.

C. M. EUAN-SMITH has gone to Buenos Ayres to examine dredging ground in the Argentine.

C. W. LININGER is in charge of the Tecolotes mine at Santa Barbara, Chihuahua, Mexico.

WILLIAM P. BLAKE has received an honorary degree from the University of Pennsylvania.

GEORGE A. SCHROTER has been appointed consulting engineer to the Dolores Mines Co., Mexico.

A. E. SAVAGE is manager for the Australian Smelting Corporation, at Kemble, New South Wales.

HOWARD D. SMITH has returned from the examination of copper mines in Inyo county, California.

R. GILMAN BROWN has returned from Chihuahua, Mexico, and is now at Ymir, British Columbia.

GEORGE BEEBE is general manager for the Cieneguita Copper Co. in the Sahuaripa district of Sonora.

JAMES F. KEMP, professor of geology in Columbia University, has returned to New York from Mexico.

H. R. PLATE, manager of the Nevada United Mines Co., at Ely, Nevada, has returned there from Denver.

D. M. BECK has been appointed superintendent of the Echo mine, at Mojave, in Kern county, California.

WILLIAM DAVIDSON has been appointed manager of the California-Nevada Copper Co., at Dalton, California.

W. A. FARISH has been examining mines at Magdalena, New Mexico. He will shortly open an office in New York.

F. WALLIS SMITH, assistant engineer with the Egyptian Mines Exploration Co., has returned to Egypt from London.

STUART R. ELLIOTT has returned from Cuba and is now superintendent for the Cleveland-Cliffs Co., at Negaunee, Michigan.

WILLARD J. MORSE has been making a tour of inspection among the A. S. & R. smelters in Mexico. He is now in San Francisco.

FREDERICK GRUNDY has returned to Los Angeles, having completed the examination of mines in Kern county, California.

H. J. ARKELL, assistant superintendent of the Siempre Viva mines, is visiting San Francisco from Bluefields, Nicaragua.

J. S. MACARTHUR is on his way home to Glasgow, having completed his examination of the Fresno copper mine in California.

FRANK ROBBINS has returned to Los Angeles, having completed a season's professional work in the Solomon River district of Alaska.

H. P. SIMPSON, assistant general manager of the Southern Department of the American Smelting & Refining Co., has resigned. He will be at New York shortly.

F. C. CARSTARPHEN, of the firm of Hewitt-Carstarphen & Co., Denver, has been doing consulting engineering work for the Portland Cement Co., at Portland, Colorado.

CLIFFORD G. DENNIS, manager of the Marfa & Mariposa Mining Co., fell down a raise 50 ft. deep, but escaped with only a few bruises. The daily press reported him seriously injured.

Dividends.

On November 5, the Bunker Hill & Sullivan Mining & Concentrating Co. will pay dividend No. 110 of \$180,000. This makes the total paid since January 1, 1906, \$1,980,000, and total to date \$7,506,000. [We shall be glad to chronicle dividends paid by other mining companies.—Editor.]

L. VOGELSTEIN & Co., New York, state that the German consumption of foreign copper for the months of January to August, 1906, as compared with 1905, was:

	Tons.	Tons.
Imports in August	12,673	
Exports in August	828	
Consumption in August	11,845	
Imports January to July	74,842	
Imports in August	12,673	87,515
Exports January to July	6,183	
Exports in August	828	7,011
Consumption January to August, 1906	80,504	
Consumption January to August, 1905	64,980	

Of the above, 10,417 tons were imported from the United States.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

POTASSIUM CYANIDE is used as a flux for the elimination of sulphur and oxygen, forming sulpho-cyanides and cyanates.

THE use of slag sand for locomotives is not to be recommended if grit can be obtained. The former makes a sticky film on the rails in wet weather.

MILLSITES cannot be located within forest reserves. The right to locate within such reserves is limited to *mineral lands*. Millsites can only be located on lands that are non-mineral.

THE slipping of locomotives on steep inclines may be avoided by spraying ammonia on the track in front of the drivers. While this is a most effective remedy, the cost is high and the effect is not lasting.

USUALLY the ventilation of raises by blowers is more economically accomplished by exhausting than by blowing. In certain special cases where the air at the bottom of the raise is bad, the reverse method may be found necessary.

IN sampling unparted and unfine gold bullion a dip sample should be taken; if lead, bismuth, or zinc be present, it is absolutely necessary to do this. The gold should be melted with nitre and cuprous chloride and a sample taken with a hot dipper.

THE use of powder that will not easily slide into the the drill-hole should be prohibited. The carelessness of blacksmiths in gauging machine steel will often result in undersized holes and consequent forcing of large sticks of powder into holes that are too small.

IN Colorado the cost of concentration in well equipped mills is as follows:

20 to 30 tons capacity daily,	\$1.50	per ton of crude ore.
40 to 50 " " " "	1.00	" " " " "
75 to 100 " " " "	0.75	" " " " "
150 to 200 " " " "	0.60	" " " " "

THE water needed in concentrating mills, including that needed for power, will average 3.5 tons per ton of ore. In badly constructed mills this may easily run up to five or even ten tons per ton of ore. If ample settling tanks are provided for the water, and it is then pumped back and again used, the amount required need be no more than one ton of water per ton of ore.

IN drilling with machines it does not pay to overload an air-compressor with too many drills, or to use a main pipe so small as to reduce the air-pressure materially. Experiments show that a drop of pressure from 75 to 45 lb. will reduce the length of hole drilled by more than 50%. Great care should be taken to have no leaks in the pipe-line, especially in the hose and couplings.

FREQUENT HANDLING of nitroglycerine causes violent headaches, especially if afterward one touches the nose or tongue with the hands. Some people soon get inured to it, but others never. As remedies, drinking cold black coffee, the application of cold wet bandages to the neck and forehead are usually efficacious. The use of acetate of morphia under proper medical supervision is also to be recommended.

THE value of an accurate survey showing the fissures and shear planes in unraveling the dynamic geology of mineral deposits cannot be over-estimated. In underground workings the strike of any fissure crossing a drift may be determined by plotting the two points at which the horizontal plane of the transit will cut the seam on each side of the drift, the dip being measured at right angles to a line joining these two points.

IN designing a mill for concentrating ores, it is important to have a sufficient fall for all the launders and for the screens, so that the stream of ore may never get blocked, and also to save the water otherwise needed to wash the ore along. Provide plenty of light, plenty of room, plenty of water, and an excess of power. With insufficient power it is impossible to keep up regular speed, stoppages and blocks become frequent, and the whole of the concentrating machinery works at a disadvantage.

THE following flux will be found to give very satisfactory results for the determination of small quantities of precious metals in cupriferous sulphides, carrying as much as 10% copper and 48% sulphur without any preliminary roasting or separation: litharge, 2,500 grams; sodium bicarbonate, 3,750; borax, 1,000; sand, 3,000; nitre, 750; some nails should also be added. A 50% copper matte ($\frac{1}{10}$ A. T.) may be fluxed in a small crucible with the following: Litharge, 60; sodium bicarbonate, 20; borax, 6; sand, 15. A borax cover should be used.

WATER RIGHTS cannot be appropriated or initiated within forest reserves without the consent of the Secretary of the Interior. The land within the reserve, except such as has been previously patented, belongs to the Government and is subject to the control of Congress. If any water privileges within the reserve are desired they must be applied for under the regulations of the Department. The latest circular on this subject was promulgated by the Department, September 28, 1905, and can be obtained by writing to the Secretary of the Interior.

IN handling broken rock and ore, the output of a man depends very largely on whether he is shoveling on a smooth surface or on the ground. Planks or iron sheets are often used, the latter being preferable, as small pieces of rock will strike into the plank and cause an obstruction. Ten cubic yards of ore in place, equivalent to 17 cu. yd. broken, should be loaded into cars within 10 hours by one man. With crushed ore and a good floor, a man working at the surface should be able to handle 20 cu. yd. of loose rock per day of nine hours.

THE absence of appreciable quantities of tellurides in the placer workings of Calaveras county, California, has often been the subject of comment. These deposits cross a number of productive veins from which tellurides are obtained in considerable quantity, notably sylvanite, petzite, and calaverite. These minerals, however, have a specific gravity of only 9 to 10 and are rather brittle. Further, their bladed or flaky nature—due to cleavage—would reduce the tendency to form placer deposits, only the rock-forming iron minerals, such as magnetite and ilmenite surviving, to be caught in the 'sands.' It is not surprising, then, that the tellurides are lost to the placer miner, since their specific gravity is only half that of gold and their cleavage and lack of ductility makes them naturally difficult of concentration. The ready decomposition of tellurides is also an important factor, for they are less stable than sulphides, and even pyrite is usually found to be oxidized, the iron of placer deposits occurring as limonite in the clay.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Tube-Mill Lining.

The Editor:

Sir—In your issue of July 28, 1906, I read with pleasure the article on 'Tube-Mill Lining,' in which the Barry honeycomb is described and illustrated.

There is no doubt that this patent is a great improvement on the silex lining which the Waihi Co. imported with their tube-mills. Anyone who has had experience with the silex lining knows how expensive and troublesome it is when used for wet grinding, and consequently will welcome any improvement in the matter of initial cost and maintenance. The ordinary iron or steel liner,

A Tube-mill Lining.

with smooth inner surface, is also unsatisfactory, for, owing to the stones sliding and thereby becoming flat, much of their efficiency for grinding is lost.

Having run tube-mills for some considerable time, grinding the sandy portion of the pulp from stamps, crushing hard ore through all grades of wire-screen from 30 mesh down to 10 mesh, and having had trouble, owing to the use of smooth iron liners, I set to work and brought out an improved iron liner, which consists of segments of a special hard mixture of iron, costing 14s. per cwt. (say, three cents per pound), when manufactured into liners. These liners are 4 ft. long and $1\frac{1}{2}$ in. thick, and are of such a width that 12 form a circle of 4 ft. diam., which is the diameter of the tube-mill. Instead of having holes cast for bolts, they have only two half holes on each long edge. Over the junction of each pair, a cast-iron bar $2\frac{1}{2}$ in. square is placed and bolted by two square-headed bolts through the lining and outer shell of the tube-mill. Thus there are 12 cast-iron bars which run longitudinally through the mill, and the effect is to form a casing of flint stones which does not slip and which protects the iron lining.

Such liners have been used for some time in the mill of the Komato Reefs Co., New Zealand, and have lasted for 18 months before being renewed. Without the square bars, the smooth iron liners only last six to eight months.

The cost of liners and bars for a 4 by 16 ft. tube-mill is £84, and two men can fix them all in position in three shifts of eight hours each; the total cost with bolts would

be, say, £90. The amount of sand passing through the tube-mill is 70 tons per day of the material discharged through the 10-mesh screen of the stamp-battery, and the finished product has the fineness that would be secured by the use of a 35-mesh screen on the battery. Thus the cost of lining is about seven-tenths of a penny, or 1.4 c. per ton of sand ground.

S. D. McMIKEN.

Komata, New Zealand, September 2.

The Position of Amalgamating Plates.

The Editor:

Sir—The article by Percy Morgan, in your issue of September 29, on 'The Position of Amalgamating Plates in the Stamp-Mill' is as full of common-sense ideas as an egg is full of meat. Although I have never seen plates so arranged, I know from my own experience that such a plan should be as near perfection as possible. I wish to add a suggestion for a further improvement, namely: Set the plates so that the pulp will flow across them sidewise instead of lengthwise, as is the usual custom. This will allow the pulp to be distributed more thinly on the plate and with the addition of a spray of clear water at the upper side, or head of the plate, with proper grade, and with plates kept in the proper condition, there will be very little, if any, amalgam that will get farther from the head than three or four feet. So I think that four to six feet would be an ample width of plate—said width to be determined by the character of the ore. If the ore is 'free-milling' and contains heavy gold easily amalgamable, then any arrangement will do, if the plates are properly attended to; but it is in cases where the ore is low grade, and where the amalgam is light and hard to hold on account of much silver, or lightness and fineness of the gold, that this side distribution of the pulp upon the plates would prove the most advantageous. If the ore is low grade, the duty per stamp per 24 hours is usually from four to six tons, and this makes too great a load for the plates as usually arranged, and the tons of water and sand passing over them scours and wears off the amalgam almost as fast as it is deposited.

J. R. SEARS.

Sutro, Nev., October 10.

Copper in Cyanide Solutions.

The Editor:

Sir—I note what C. A. Arents says about copper precipitating on zinc shaving, and, having had a similar experience, I can agree with him that copper may not be a hindrance to good precipitation.

Two years ago I was operating a cyanide plant in the desert country, treating a dump of old pan-mill tailing. One mill had burned down there, and there were numerous small pieces of burned copper plate mixed with the sand. The copper did not begin to show until the plant had been running about four months. The concentration of copper in the solution was probably due to the fact that no wash-water or weak solution left the plant except that existing in the residues as moisture.

Copper began to show first on the fresh zinc that was put in the lower boxes and in a month or six weeks it had worked up to the head boxes. I was somewhat alarmed at first, and tried to keep it off by adding cyanide to the filter-box. The stronger solution would take it off in a few hours but only to be back again the next morning. I took daily samples (for a while) of the solution leaving the boxes, but they only assayed a trace to a few cents, when the solution entering averaged about five dollars per ton.

The gold seemed to precipitate on the copper-covered

shaving so that there were shades from bright copper, bronze, to black. There was also mercury in the sand which was taken up by the solution and precipitated, causing some of the shaving to look like silver.

The value of the precipitate shipped was about \$16 per lb. before the copper began to show, and gradually it decreased to about \$8 per lb. But with the exception of making a lower grade precipitate, the copper did no harm whatever, and the precipitation was as good after as before.

E. D. CHANDLER.

Rochford, S. D., October 17.

[Referring to the useful contribution from Mr. C. A. Arents, we are informed by him that 0.75% copper per ton should have read 0.75 lb. copper per ton of ore.—EDITOR.]

Gold Dredging.

The Editor:

Sir—In the issue of your paper of January 27, 1906, under the heading of 'Gold Dredging,' J. H. Curle asks seven specific questions, and the article goes on to give a great deal of valuable information which, on two points, I venture to think, is a little misleading. In referring to the Yuba district, Mr. Curle states that a large area of gravel 90 ft. deep gives good returns, and that the dredges there are to work to that depth. Though the drilling in the Yuba field discloses the fact that gold values are contained at least to a depth of 115 ft., it has only been considered advisable to build boats fitted to dig at their greatest advantage, to depths not over 70 feet.

This article was published in January, 1906, and at the present date there are ten dredges at work. All of these are equipped to dig to 64 ft. below water line, and the deepest work that is, or has been, done there is at a depth of 72 ft. below water line. Under the conditions prevailing on the Yuba the water line is, as a rule, only a few feet below the actual surface—in some cases, indeed, the dredging ponds have to be kept pumped out so that the surface of the dredging ground may be above water and in order that the digging ladder may reach the depth mentioned. This, so far as I am aware, is the greatest depth to which dredging has been carried in any part of the world, but as the best values in dredging lands in the majority of cases lie close to the bottom of the digging it is not hard to see that an overburden, if commercially unproductive, simply tends to reduce the profit—or, in other words, to lower the average grade per yard of the material which it is necessary to handle.

The other point to which exception may be taken is contained in the concluding sentences where it is inferred that Oroville and the Yuba districts should be studied as the most modern examples of up-to-date prospecting, designing, and dredging. The name of Folsom is only conspicuous by its absence. In my humble opinion this district should rank at least with the others for all and more of the qualifications mentioned. It is not only the most important as having the largest available area of dredging ground; but (in some cases under unique conditions) illustrates the handling of the largest yardage per boat of any locality in the world, and—as far as can be learned—at as low an average cost per yard.

I have recently completed an extensive examination of the dredging fields of Oroville, Yuba, and Folsom in the Sacramento valley, and have investigated fully most of the points embodied in Mr. Curle's seven specific questions. Those questions were:

1. How many payable or probably payable dredging areas are known in the world, and what is approximately their gross extent? Which are the likeliest countries to prospect?

2. How much gold is produced yearly by dredges and how much of the production is profit?
3. How many dredges are now working at a profit?
4. How many dredges that were once worked are not now worked, and what were the reasons for their stoppage? How much money do these represent?
5. What are the precise costs in different localities? How are costs affected by: *a.* Type of dredge; *b.* nature of deposit; *c.* nature of power; and *d.* climate?
6. What is the best system of prospecting dredging ground? How should such system be adapted to different kinds of ground? Is drilling as effective as sinking shafts or paddocks? What is the average recovery of the gold contents as shown in prospecting? Why are favorable results in prospecting often falsified in practice?
7. Assuming prospected or otherwise proved ground to represent 'ore blocked out,' which is the correct basis of valuation for such ground?

As the results of my investigations are shortly to appear in print, I shall simply refer to Mr. Curle's queries in a brief manner.

No. 1 does not apply to this locality.

No. 2. This is a difficult question to answer accurately in detail, because the information is not fully obtainable. However, assuming that at Oroville, the average total working cost is seven cents per yard, the average recoverable value of the gravel 14c., and the annual yardage produced about 19,200,000; then there is a total annual production of \$2,688,000, of which \$1,344,000 is net profit. On the Yuba the annual yardage is from 9,600,000 to 10,200,000. The recoverable value of the gravel has been estimated at 20c. per yd., then assuming that the working cost is 5.5c. per yd., the total annual production is \$2,000,000, and the profit \$1,450,000.

At Folsom figures of this sort are difficult to obtain, but the average value over the whole tract is probably not over 11c., though in places it will run much higher than this figure. Taking the average working cost as 5c. per cu. yd., and the total annual product as 8,500,000 cu. yd., the profit is estimated at \$510,000.

Therefore in the three districts an approximate estimate of the total annual production, the average recovery per yard, the average cost of working per yard, and the total annual net profit may be summarily expressed in tabular form as follows:

District.	Annual operations in cu. yd.	Production.	Recovery per cu. yd. in cents	Cost per cu. yd. in cents.	Annual profit.
Oroville	19,200,000	\$2,688,000	14	7	\$1,344,000
Yuba	9,600,000	2,000,000	20	5.5	1,450,000
Folsom	8,500,000	935,000	11	6	510,000
Total	37,300,000	\$5,623,000			\$3,304,000

No. 3. In the three districts there are 49 dredges in operation, of which, say 41, have been working over nine months. Of the latter number probably over 90% are working at a profit, while undoubtedly all of the remaining eight will pay dividends.

No. 4. Only two dredges that are not now working are still fit for operation, all the others having, through service, become mechanically unfit for use. Of these two, one is of too small capacity and is practically worn out, while the other is also of ancient design, but could be remodeled and used. After litigation it was sold at sheriff's sale. The property on which it operated is still commercially valuable from a dredging point of view. The two dredges probably originally represented about \$95,000.

No. 5. The costs have been given in the answer to question No. 2.

a. The type of dredge affects the cost of production chiefly as regards its digging capacity, this being favorable in proportion to the increase in size of buckets up to at least $7\frac{1}{2}$ cu. ft., and probably up to 13 cu. ft., where proper repair facilities are available and several machines are operated under one management. Fixed costs are reduced in the larger machines and output is increased.

b. The nature of the deposits affects the cost as follows: Hard ground and large boulders require more power and there is greater loss of time, one of the main factors in increasing cost. Moreover, the cost in labor and repair of parts is increased.

Clayey ground requires more disintegration and causes loss of gold over the stacker.

c. Electric power is the only form used in the districts of Oroville, Yuba, and Folsom, and is undoubtedly superior to steam, not only as affects reduction of cost, but on account of its advantageous application and control.

d. Climate practically does not enter into consideration in this region except as regards high or low water in the flood season. Even then it does not affect the cost to any degree.

No. 6. Undoubtedly the most effective practical system of prospecting dredging ground is by shaft. Drilling costs on the average \$2.50 per ft., and is often very unsatisfactory in results, both as regards information on values and nature of ground. In comparison with the drill as a method of sampling, a shaft is more thorough and costs less per foot above water-level; even below water-level, where pumping is necessary, it is to be recommended, as it can be referred to afterward in ascertaining the exact nature of the ground. The cost of shaft sinking by the 'China' method varies between 90c. and \$1.50 to water-level, and the increase below this point varies with the amount of water. These figures include cost of panning.

The ratio between estimated value of ground by drilling, and actual recovery by the dredge, is not a fixed proportion, but may generally be said to increase in constancy over a large area roughly in proportion to the number of holes per acre. Single holes are rarely indicative of the value of adjacent ground, though a somewhat arbitrary rule that seems to apply in practice, is: Where a hole gives excessively high results the recovery by dredge at that spot is usually lower, and vice versa.

The care with which the computation of the value of a dredging property from bore-holes is made should be in exact proportion to that taken in computing, by bank measurement (after clean-up), the cubic content dredged. The results are often vitiated by old workings, clay, etc., encountered by the drill.

No. 7. The method of valuing prospected area may be generally compared to that of valuing a mine from sampling and assaying, except that in the former case the results are not so consistent or accurate. One authority of a very wide experience states that before deducting from the 'prospect' value of a property, the cost of working, interest, depreciation, etc., he reduces the estimated value as obtained from drilling by 40%. As I have already taken considerable of your valuable space, I shall refer to the question of sectionalizing a dredge in another issue.

In the criticism of Mr. Curle's article by C. W. Purington, appearing in your issue of July 28, there are also several points touched upon which, in my opinion, may be themselves criticized. The generalization that "flood plains reduced nearly to base level, in which streams meander are * * * the first requisite for gravels fit for dredging" is disproved by the conditions in the Sacramento valley. Neither the territory on the Yuba where the river bottom, with its accumulation of tailing

overburden, forms the gold-bearing material, and the bench gravels of the American river at Folsom, together forming probably half (in value) of the available fields, come under this head.

The large dredging area adjacent to the American river, near Folsom, seems to be almost ignored by both Mr. Curle and Mr. Purington, though undoubtedly excellent and remunerative work is being done there today.

Referring to Mr. Purington's criticism of question No. 4, I do not understand Mr. Curle's question to refer to every dredge that has *ever been built*, as naturally a dredge's life is only that of the hull, and under early conditions this was not very long lived. As far as his remarks refer to the districts of Oroville, Yuba, and Folsom, they seem rather extravagant.

Mr. Purington states that probably not over 100 dredges are working at a profit in the world. As there are probably 48 working at a profit in California, and I am credibly informed of at least four others in the United States, the New Zealand practice, where there are over 200 in use, must be a losing business.

Contrary to the opinion expressed, I contend that shaft sinking is feasible in the large majority of cases, and is much cheaper than drilling. Even where water is encountered the cost in 90% of cases is not increased in undue proportion to results. The question of valuation is one that Mr. Purington covers considerable space in treating, but the sum of his remarks seem to be that "to enquirers like Mr. Curle," at least, no proper system of valuing the ground to show net profits has been discovered. I confess that I cannot see any particular difficulty in computing the purchaseable value (which, by the way, is the real test), of a properly examined and prospected dredging area other than those that occur in mine valuation. The increased risk incurred in prospecting dredging ground is offset by the possibility of change in the nature of orebodies with depth, and of necessitating different and more expensive treatment at surface. No competent engineer would value any property, either dredging or lode, without making similar and proper allowances for all expenses, including preliminary and amortization, etc., and therefore I do not see why exceptional stress should be laid on those points when applied to dredging.

D'ARCY WEATHERBE.

Bisbee, October 22.

How Nuggets May be Made.

The Editor:

Sir.—Mr. Charles S. Palmer, in your issue of September 30, outlines very instructively the laborious methods of nature in making nuggets. That method may be good enough for the 'highly trained' engineer. I have, however, a much simpler method, without any college frills on it. Take molten metal; pour from a spoon drop by drop into a vessel filled with wheat; take the nuggets thus formed and boil them in coffee. If worn in strings across the breast they form a splendid insignia for us real mining experts.

PROMOTORS G. HELPER M. E. (not E. M.)

London, October 10.

GEOLOGY is, as it were, the biology of our planet as a whole. In so far as it comprises the surface configuration and the inner structure of the earth, it answers to morphology; in so far as it studies changes of condition and their causes, it corresponds with physiology; in so far as it deals with the causes which have affected the progress of the earth from its earliest to its present state, it forms part of the general doctrine of evolution.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

In an action by the lessee of a mine against the lessor for damages for eviction and for the value of ore taken, and where the veins included within the description were in dispute, and the lessor failed to produce his office map, referred to in the description, the court held that such failure to produce the map, warranted the presumption that the map would show that the lessees' contention was correct.

Isabella Gold Min. Co. v. Glenn, (Colo.), 86 Pac., 349.

Where the lease of a mine granted the lessee the right to extract ore from all veins outcropping "within and belonging to the southeasterly five hundred feet of a certain lode mining claim" the court held that the lessee was entitled to all outcropping veins and all others which for any reason belonged to the five hundred feet described, and was not limited to veins which both belonged to and had their apices in the claim described.

Isabella Gold Min. Co. v. Glenn, (Colo.), 86 Pac., 349.

Where it was shown that the lessor of a mine evicted the lessee and extracted large quantities of ore, it was held that under such circumstances the burden of proof was upon the lessor to prove the amount and value of the ore taken by such lessor and any subsequent lessee.

Isabella Gold Min. Co. v. Glenn, (Colo.), 86 Pac., 349.

It is the duty of the owner of a mine to notify the miners of an unexploded charge of giant powder, and the delegation of this duty to a foreman will not relieve the owner in case of injury, in case the foreman fails to give such notice.

Bone v. Ophir Silver Mining Co. (Cal.), 86 Pac. 685.

A purchaser agreed to pay seven thousand one hundred dollars for a certain mining claim, and one hundred dollars cash was paid and the remainder to be paid at a certain future date. The balance of the purchase price was deposited in bank with instructions to pay the same to the seller on presentation of a receipt of the receiver. It was held that the bank was justified in paying the money on presentation of the receiver's receipt.

Hunt v. Capital State Bank (Idaho), 86 Pac. 706.

Under a contract to pay a certain price per ton for ore deposited in the chutes ready for hoisting, payments to be made on certain days of each month, for the coal hoisted, it was held that the plaintiff could recover for coal deposited in the chutes, though it was not hoisted because of water rising in the mine.

Ward v. Eastwood (Cal.), 86 Pac. 742.

Where the purchaser of a mine agreed to pay the cost of procuring a patent to a mining claim, and the seller proceeded to and procured the patent, the purchaser was held liable for the cost of such patent.

Hunt v. Capital State Bank (Idaho), 86 Pac. 786.

Engines, boilers, pumpers, coal and water cars, rails, tippers, screen bars, tools, and implements used together in connection with the operation of a coal mine, constitute improvements and are consequently assessable as real estate, and such property cannot be sold to satisfy a personal property tax.

Doe v. Tenino Coal & Iron Co. (Wash.), 86 Pac. 938.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The rocks from Jerome, Ariz., marked A. G., are: No. 1. Obsidian pebbles; No. 2. Rhyolite-tuff.

The mineral from F. H. B., of Melbourne, Australia, is ilmenite, the oxide of iron and titanium.

The specimens from A. B. H., of Cima, Cal., are quartz and chlorite containing plates and grains of specular hematite.

The specimens from Iron Springs, Idaho, marked T. D. and X. T. D., are quartz containing veins of talc and graphite.

The specimen from Alleghany, Cal., marked T. H. B., is talc-schist and is often associated with serpentine or chlorite-schist as country rock.

The rocks from C. F. G., of Sisson, Cal., are: No. 1. Compact dark green chlorite; No. 2. Quartzite; No. 3. Serpentine containing pyrrhotite.

The rocks from H. P. A., of San Antonio, Tex., are: No. 1. White quartz; No. 2. Basalt; No. 3. Amygdaloidal basalt with calcite in the cavities.

The rocks from J. H. P., of Homestead, Ore., are: No. 1. Serpentinized rock containing chalcopryrite and pyrite; No. 2. Hornstone; No. 3. Bornite in jasper; No. 4. Mixture of jasper and serpentine.

Specimens from W. W. R., of Stewart, B. C., are: No. 1. Siliceous limestone; No. 2. Quartz mixed with chlorite; No. 3 and 4. Pyrite and pyrrhotite altered to limonite; No. 5. Carbonaceous rock.

The specimens from E. R. Mc., of Reno, Nev., are rocks decomposed into clay, micaceous chlorite, and brown limonite. Much pyrite or pyrrhotite was present which has been altered to limonite, but no nickel is present in the samples.

A BIT OF CORNISH FUN.—The manager of a gold mine sent an imperative demand to a shareholder for the payment of a 'call' and received this reply:

"Dear Sir.—I have your letter of this date and note that your directors propose to proceed against me. Your prospectus stated that one of the objects of your company was to seek, win and work gold in—and elsewhere. Things not turning out well in—your directors apparently consider it their duty to seek, win, and work gold elsewhere, i. e., out of me. I can assure you, however, that I am not in an auriferous vein; the only lode I possess is a load of debt, and as a gold mine I shall be a failure. Your prospectus estimates a yield of 1 oz. of gold per ton on 30,000 tons of quartz crushed per annum. You may 'crush' me, but you will find that I will not yield nearly so much. My person (which for the purpose of this calculation may be considered quartz), weight, roughly speaking, 10st., and if crushed immediately I estimate that it would yield as under: Gold, nil; silver, 3s.; copper, 4½d. total, 3s. 4½d. Deduct cost of crushing, say £5 5s.—Yours faithfully.—"

THE development of every branch of physical knowledge presents three stages, which, in their relation, are successive: observation, experiment, and speculation.

Three Weeks in Mexico.—IX.

Pachuca—Its Early History.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

Pachuca is approached from Mexico City over a railroad that traverses the wide volcanic plains, through vast plantations of *maguey* whose serried lines stretch out like an army in skirmishing order. A journey of 62 miles brings the traveler to a white town at the foot of brown hills that rise to a range 1,500 ft. above the valley, which is 8,200 ft. above sea-level. The morning I saw them first, the mists still hid their summits and gave them the possibility of a greater height. Pachuca is like far-away Kalgoorlie in the matter of dust, it swirls round every street corner and smothers the picturesque in the dry folds of the commonplace. In the plaza, among the graceful pepper trees, there are two eucalyptus, fifteen to

the canyon de Taylor. Another reminder of the Cornish invasion is seen in the fine stone mansion, half smothered in beautiful *bougainvillea*, of Mr. Francis Rule, whom his countrymen call Capt. Frank Rule, and the Mexicans, Don Pancho, an honored and successful mining engineer.

Pachuca has a population of 40,000, and of this number 7,000 work underground. The district produces 6,000,000 oz. silver per annum and 30,000 oz. gold, representing 9,000,000 pesos or \$4,500,000.

Most of the lodes that are productive today were discovered by the *conquistadores* and their immediate (Spanish) successors, aided, to some extent, by the natives (Aztecs). The Spanish pioneers sought for gold placers and extracted the metal—not much—that they found, by washing, supplemented sometimes by amalgamation. What silver ore they encountered, they smelted with carbonate of soda (the *tequesquite* of the Spaniard and the earlier *tequixquilt* of the Aztec), a supply of which came

Sketch Map of Mexico.

twenty years old, whose dark blue foliage and ragged columns told of a land which was unknown to the civilized world for 250 years after the Spaniard invaded Mexico. The antiseptic odor of these gum trees recalled to me many a glorious day spent in the Australian Alps.* But Pachuca differs from any modern mining town in English-speaking countries in every respect except its dust, and even that has a composition all its own. The corrugated shanties and the white tents of ephemeral mining camps are here replaced by a solidity of construction that bespeaks a hereditary occupation. Massive stone buildings overlook the narrow cobble-paved streets and some of them have architectural pretensions, as for example the offices of the Real del Monte Mining Co., an enterprise of historic continuity and associated with names famous in mining, for John Taylor & Sons were engineers of the old company sixty years ago. Even to this day John Taylor's name is honored, and in the Santa Brigida mine there is a level that continues to be called

from the lagoons in the valley—for instance, in the lake of Tezcoco. Their fuel was charcoal made from fir and oak; possibly also they used some lead ore to collect the silver in their rudimentary smelting operation. When Bartholomé de Medina invented the *patio* process at the Hacienda Purisima Grande he revolutionized the silver mining industry. This was in 1557; up to that time only the richest mineral could be smelted and there was no process for treating the low-grade ore. Medina was the first to apply amalgamation to silver, despite its much earlier application in gold mining. This was a basic improvement, but he also elaborated the method for treating silver sulphides by chloridizing with salt in the presence of copper sulphate, using mules to mix the charge. This is the *patio* process, so called because it takes place in an inner court or yard (the *patio*) and from Medina's day to this, for 350 years, it has been the characteristic feature of Mexican metallurgy.

In 1739 Pedro José Romero de Terreros, who had made money by mining in Queretaro, visited Pachuca and became impressed with the Real del Monte district. He spent his capital, said to have been \$60,000, and borrowed more to carry out his explorations, but finally he

*The pepper trees which ornament Pachuca also came from a far country; they are called the Peruvian tree, having been introduced by one of the last of the Spanish viceroys, who brought them from Peru, where he had previously held office. The eucalyptus was introduced thirty years ago by the minister de fomento, but it has not done very well, the soil being too dry.

struck a bonanza and won a big fortune. He gave the king of Spain a battleship and other large gifts; in consequence, he was ennobled. As Count of Regla he became the founder of a family of successful miners. They worked the mines until 1819, when the disorderly condition of the country, due to the revolution against the Spanish Government, caused operations to cease. A few years later the mines were sold to an English company, which took charge in 1824. The doings of that company are still mentioned in every Mexican guide-book, the writers of which dwell with gusto on their wild speculation in London and their reckless extravagance in Mexico. The £100 shares rose to £16,000 apiece, almost before a start had been made; enormous sums were spent at the mines, no less than 1,500 tons of machinery being hauled across the country from Vera Cruz. In 1848 the company went into liquidation, after extracting \$16,000,000 in silver and spending \$20,000,000. In 1850 a Mexican company was organized, and it is this ownership that survives without

closed by massive walls, which at one time served as protection from assault, but nowadays they are retained for a different reason. They safeguard the dumps, which are recognized as having a possible value in the future, for the *peones* are born thieves and their pilfering is a constant nuisance to the mining companies. For this reason also the reduction works, or *haciendas*, are all enclosed within lofty walls, which are entered by arched doorways at which a watchman stands. At noon the women crowd at these entrance gates with baskets containing the dinner of their men, who meet them there; they often squat down beside the wall to have a chat and share a smoke, until the lengthening shadow marks the time to resume labor.

All the *peon* employees of the mines and mills are rigorously searched by the *velador* as they pass out through the gate of the enclosing wall. The ordinary *peon* laborers are cheap enough, but it is what they steal that makes them costly. They are inveterate thieves.

Pachuca. Patio Mills in Foreground.

important change to the present day.† The first manager of the Mexican company was the last manager of its English predecessor; that was John Buchan, obviously a Scotchman; and despite the change of ownership there was a continuity of management, the Spanish and the British members of the staff co-operating loyally. During the Maximilian days and the later successive fights for the presidency, the mines at Pachuca suffered from the depredations of the military, partly soldiers but mostly bandits. Stories are told of the miners having to live underground for days at a time and of the money that was buried in the levels when people at surface were being robbed without compunction. Up to 1890 it was necessary to carry a revolver in the streets of Pachuca, even in the daytime. The Real del Monte office, for example, is a massive stone structure which originally did duty as a fortress; the round towers, slotted for rifle fire against attacking forces, still stand at each of the four corners of the building. Every mine even today is en-

All sorts of precautions are taken. At the Hacienda Loreto, the manager proposes to make his men pass through a water tank and compel them to shout "*Viva Mexico*" three times in order to detect any amalgam that they may have in their mouth. And they have other schemes for overcoming their excessive poverty otherwise than by earning scanty wages. For instance, there is a great deal of mutilated coinage and also of counterfeits. When pay-day arrives, the workmen, in sweeping their silver across the office-counter, will try to palm off spurious coins by claiming that the cashier gave it to them. The trick is detected by the warmth of the coin which the man has held in his hand just before passing it in. Punishment for this trick is severe, as it is an offence against the Federal Government; several years in jail is not uncommon.

At Pachuca the application of mechanical invention to a basic industry is amusingly illustrated by the fact that even *tortillas*—the common pancake of the country—are made by machinery. The people of Pachuca patronize the establishment where this is done because the cost is

†Since this was written the Real del Monte mines have been sold to a Boston corporation. The Anglo-Ultie invasion has begun!

one half that of the hand-made article and they are equally palatable. The excellence of the local *tortilla* may explain the vigor of the native miner; for the *barateros* of Pachuca are recognized to be the best miners in Mexico; they have learnt from the Cornish who settled in the district more than fifty years ago and intermarried with the natives. The Guanajuatenses, or men from Guanajuato, have the reputation of being quarrelsome and less efficient as miners,—which may be for lack of admixture with a strain of Cousin Jack, but we do not make the suggestion with any confidence.

The natives of this district, like most Mexicans, are wonderfully clever in estimating the silver content of an ore within their own stamping ground; stolen ore is invariably bought by valuation at sight. Even the tributers (those that work on tribute or *partido*) sell the ore they mine to the proprietary company on the basis of an estimate of its assay-value made at sight by an official termed the *rescatador*; if the appraisal is not satisfactory, they can sell their ore elsewhere. Tributers get an eighth of the stuff they mine—that is, one sack in every eight—the remainder going to the company. This is the system at the Real del Monte mines; other companies work chiefly on contract.

We, that is Robert M. Raymond of El Oro and the writer, made an interesting visit from Pachuca to the neighboring mining town of Real del Monte; this courtesy, and much information, we owed to Señor Don Carlos de Landero, the managing director and one of the most accomplished of Mexican mining engineers. In a large carriage drawn by four mules, with a driver and footman dressed in the picturesque uniform of the company, to the crackling of the whip and the heavy rumbling of the wagon over the cobblestones of Pachuca, we started on the morning of October 30, before the mists had uncovered the crests of the range where lies the treasure unexhausted despite the mining of three and a half centuries. Emerging from the narrow streets, the road cuts the edge of the valley and winds slowly among the brown hills, dotted with wild *maquey*. At the San Francisco shaft of the Santa Gertrudis company we saw a large pumping engine of the Cornish type, built by Bickle & Co., of Plymouth, in 1898. The cylinder is upright and 90 in. in diameter; the stroke is 9 ft. and the pump-column 18 in. The capacity is $3\frac{1}{2}$ cu. m. or 1,000 gal. per min., from a depth of 400 metres. This pump was chosen by Capt. Frank Rule under a former administration; it was obtained at an enormous cost on account of the difficulties of transport and erection. Although made in 1898, it was not at work until 1902. But once erected, the pump has proved most efficient. The boilers are single-flue with two fire-places and nine Galloway tubes, so as to be well adapted to the use of the mine water.

The distance from Pachuca to Real del Monte is six to eight miles, by the various roads. Haulage of ore costs three *pesos* per ton, the road crossing the summit of the range, 1,100 ft. above Pachuca. Only one trip per day is made.

Nearing the divide, the road crosses the red outcrop of the Vizcaíña lode, famous in local mining annals as that which gave such wealth to the first Count of Regla. The story is worthy of repetition, although it has several versions, the most reasonable of which is here offered. In 1739, Pedro Terreros, who is said to have made \$60,000 in the mines of Queretaro, happened to visit Pachuca. He was an experienced miner. Becoming interested, he abandoned the journey to Spain, and started mining at Real del Monte. Humboldt speaks of "the vein of la Biscaina or Real del Monte;" it is now spelt Vizcaíña (pronunciation remaining unaltered, but the Mexican orthography being substituted) and it is evident that the name was

given after Terreros came there, for it refers to the country of his nativity, Biscay—most sea-goers know the Bay of Biscay. Terreros was successful, but the increased flow of water compelled him to abandon the main Santa Brigeda workings when they were 120 m. deep. In the early part of the eighteenth century the water in mines was hoisted by methods which still survive, namely, hide bags and a windlass. Even in Humboldt's day, sixty years later, much the same practice obtained. He says: "A bag full of water suspended to the drum of a *barritel* with eight horses (*malacate doble* or double horse-whims) weighs 1,250 lb.; it is made of two hides sewed together. The *malacate doble* has four arms, the extremity of each arm has a shaft (*timon*) to which two horses are yoked. The diameter of the circle traveled by the horses is seventeen *varas* and a half (that is, $47\frac{1}{2}$ ft.); the diameter of the drum is twelve (32 ft.). The horses are changed every four hours."

However, the influx of water was finally overcome in miner-like fashion by driving a drainage adit (*socubon*) into the hillside. Humboldt says: "A very enterprising individual, Don Joseph Alexander Bustamante, was courageous enough to undertake a level near Moran; but he died before completing this great work, which is 2,352 metres in length from its mouth to the point where it crosses the Biscaina vein. * * * The level was only finished in 1762 by Don Pedro Terreros, the partner of Bustamante. * * * The level of Moran traverses the Biscaina vein in the pit of San Ramon at a depth of 210 metres." But these worthy miners were plain 'José' and 'Pedro' until long afterward, when their wealth and public spirit led to their ennoblement. This adit of over a mile long was started in 1850 and was finished in twelve years; the smaller veins intersected during the progress of the work furnished funds for its continuation, but before it was completed the projectors of the enterprise were—as is usual in mining romance—down to their last penny. When the vein was cut below the Santa Brigeda shaft, the adit was in bonanza. This was at 210 metres below surface. The orebody was worked for twelve years and the money secured by Terreros enabled him not only to equip the old mine but to buy large plantations in the vicinity. He became enormously wealthy; "this muleteer and illiterate shop-keeper," so says the chronicle, became Count of Regla. When his children were baptized the procession walked on bars of silver. Furthermore, he loaned money to his sovereign—this was one of the privileges of rich men in those days; nowadays they buy yachts and sandbag their fellow Croesus. Humboldt says that Terreros "known by the title of Count of Regla, as one of the richest men of his age, had in 1774 already drawn a net profit of more than 25 millions of *livres tournois* (\$5,208,750) from the Biscaina mine. Besides the two ships of war that he presented to King Charles the Third, one of them of 120 guns, he lent five millions of francs (1,041,750) to the court of Madrid, which has never yet been repaid him."

PURE COPPER cannot be cast in sand without considerable difficulty; in fact, some deoxidizer is always used. For common copper castings from 2 to 5% zinc is generally added to get sound castings; but for electrical work this is useless. The only way to get good electrical castings is to melt pure electrolytic copper in a plumbago crucible under a thick layer of charcoal. When thoroughly melted add 2% silicon copper and stir it in with a stick, and cast as soon as ready. Practical experience alone will show the correct temperature for casting copper in sand molds, and the proper temper of the sand. It must not be cast boiling, but a fairly high temperature is necessary.

Mineral Output of California.

The State Mineralogist, Mr. Lewis E. Aubury, has issued from the State Mining Bureau a tabulated sheet showing the output in amount and value of the mineral products of California, for the year 1905. This appears somewhat later than usual as the records of many companies were destroyed in the great fire and it took a longer time to get corrected addresses and obtain the desired information.

The following table shows the yield and value of mineral substances of California for the year 1905, as per returns received at the State Mining Bureau, San Francisco, in answer to inquiries sent to producers:

	Quantity.	Value.
Asbestos	112 tons	\$ 2,625
Asphalt	40,304 "	285,290
Bituminous rock ...	24,753 "	60,436
Borax	46,334 "	1,019,158
Brick	286,618 M.	2,273,786
Cement	1,265,553 bbl.	1,791,916
Chrome	40 tons	600
Clay	133,805 "	130,146
Coal	46,500 "	144,500
Copper	16,997,489 lb.	2,650,605
Fuller's earth	1,344 tons	38,000
Gems	148,500
Glass sand	9,257 tons	8,121
Gold	19,197,043
Granite	228,738 cu. ft.	353,837
Gypsum	12,850 tons	54,500
Infusorial earth	3,000 "	15,000
Lead	533,680 lb.	25,083
Lime	616,995 bbl.	555,322
Limestone	192,749 tons	323,325
Lithia-Mica	25 "	276
Macadam	1,440,455 "	942,503
Magnesite	3,933 "	16,221
Marble	73,303 cu. ft.	129,450
Mineral paint	754 tons	4,025
Mineral water	2,194,150 gal.	538,700
Natural gas	148,345 M. cu. ft.	102,479
Paving blocks	3,408 M.	134,347
Petroleum	34,275,701 bbl.	9,007,820
Platinum	200 oz.	3,320
Pyrite	15,503 tons	63,958
Quicksilver	24,655 flasks	886,081
Rubble	1,183,802 tons	774,267
Salt	77,118 "	141,925
Sandstone	302,813 cu. ft.	483,268
Silver	678,494
Slate	4,000 squares	40,000
Soapstone	300 tons	3,000
Soda	15,000 "	22,500
Tungsten	52 "	18,800
Total value	\$43,069,227

The total yield of metallic substances, including gold and silver, was, for the year, \$23,523,984 and in these are also copper, quicksilver, chrome, lead, pyrite, platinum, and tungsten. This is the first year the last substance has been produced in California.

The value of non-metallic substances was \$2,145,930 including borax, salt, soda, mineral waters, asbestos, coal, Fuller's earth, gypsum, infusorial earth, lithia-mica, magnesite, mineral paint, and gems.

The total value of hydrocarbons and natural gas was \$9,456,025. The hydrocarbons include asphalt, bituminous rock, natural gas, and petroleum. In 1904 the product of petroleum in the State was 29,736,003 bbl., worth \$8,317,809. The increase in output for the year is thus shown to be 4,539,698 bbl. and in value \$690,011.

In structural materials, the total value for the year was \$7,943,288, an increase over 1904 of \$668,442. These materials include lime and limestone, macadam, glass, sand, marble, granite, sandstone, paving blocks, rubble, slate, soapstone, brick and pottery clays, and cement. In the last substance the increase in the output for the year amounted to 296,015 bbl., the number made in 1905 being 1,265,553 barrels.

The relative value of the principal mineral substances of the State, as shown by the tables, is as follows: 1, gold;

2, petroleum; 3, copper; 4, cement; 5, borax; 6, macadam; 7, quicksilver; 8, rubble.

While gold is still the leading mining product, its yield no longer puts the greatest gold-producing county in the first place. The petroleum of Kern county and the copper of Shasta give them precedence. Gold is more widely distributed than any other substance thus far mined in California; 34 counties out of the 57 in the State showing a gold yield in 1905, and it is known to exist in several others. Nevada county produces more gold than any other in the State, its output for 1905 having been \$3,179,715 gold alone. Butte county, with its numerous dredgers, comes next. Kern county is now the largest mineral producer in the State; its output of ten substances bringing its total value last year up to \$4,912,095. Its petroleum alone was valued at \$3,174,966, which was not quite up to the Nevada county gold. Shasta county falls into third place for last year, instead of being first as it has been for several years, its copper production having fallen off materially, mainly on account of the cessation of smelting operations at Keswick by the Mountain Copper Co. Shasta's entire output for all minerals last year was \$2,579,014.

The following shows the output of the respective counties for 1905, as arranged by the State Mineralogist. He explains, however, that certain substances have to be placed in the 'unapportioned' column so as to conceal the identity of single mines in certain counties. For this reason it is necessary to put under this heading, borax, soda, coal, portland cement, and a few other substances formerly credited to certain counties. If credited to the exact county, where there is only a single operator, private business would be made public. Under these circumstances, the figures of values of output in some counties do not actually represent their relative rank, as some of the products may be placed under 'unapportioned.' The total values of such substances appears in the main table, but not in the table of counties. Out of 57 counties of the State, 54 made some mineral production in 1905:

County.	Production.	County.	Production.
Alameda	\$ 662,687	Plumas	\$ 284,497
Alpine	575	Riverside	558,369
Amador	2,490,755	Sacramento	881,852
Butte	2,621,104	San Benito	360,145
Calaveras	2,415,627	San Diego	231,945
Colusa	289,454	San Bernardino	820,026
Contra Costa	197,493	San Francisco	456,042
Del Norte	10,612	San Joaquin	146,915
El Dorado	467,566	San Luis Obispo	189,592
Fresno	2,734,164	San Mateo	203,936
Humboldt	53,628	Santa Barbara	1,601,217
Inyo	222,596	Santa Clara	470,130
Kern	4,912,095	Santa Cruz	296,349
Kings	33,000	Shasta	2,579,014
Lake	271,437	Sierra	520,990
Los Angeles	2,234,354	Siskiyou	806,877
Madera	183,987	Solano	201,091
Marin	207,835	Sonoma	318,871
Mariposa	393,592	Stanislaus	52,365
Mendocino	24,510	Tehama	9,000
Merced	3,500	Trinity	708,255
Mono	320,124	Tulare	32,313
Monterey	23,121	Tuolumne	1,389,774
Napa	261,910	Ventura	345,093
Nevada	3,214,828	Yolo	200
Orange	738,264	Yuba	325,384
Placer	798,644	Unapportioned	3,491,523
Total	\$43,069,227

NERNST LAMPS are made in various sizes for use on alternating current circuits of 110 or 220 volts. They give a bright and steady light for shaft work, underground pump-stations, etc. Although the first cost is slightly higher than that of the ordinary incandescent lamp, the consumption of current is much lower, being only 88 watts for a light, equivalent to three 16 c.p. glow-lamps.

Some Tailing Samplers.

Written for the MINING AND SCIENTIFIC PRESS
By R. GILMAN BROWN.

It is hardly too much to say that of tailing samplers there should be no end, and the description of good devices of this class at least serves the laudable end of removing the underpinning from those who still evade the use of such devices. It can not but be remarkable that, even at this late day when so much has been written

which the tailing flows, *D* is a sampling box with $\frac{1}{16}$ -in. slot suspended by the hangers *J J*, which are free to swing. From the spout of *D* the sample runs into the receptacle *B*; the apron *M* guards against splash, and *C*, with its inclined cover, further protects the sample from accidental salting. When the sampler is in the position shown, the tailing-stream falls into the hopper *K*. The actuating device is shown at the right of Fig. 1. *F* is a water pipe with a regulating valve, *E* is a water can secured eccentrically on a crank-

Tailing Sampler in Use at the Ymir Mill, B. C.

of the need of a systematic check on milling work, it should be rather the exception to find automatic samplers installed in smaller mills. It is not the every-day mechanic who can devise a machine which at regular intervals can be self-instigated to take a quick cut through a stream of tailing, and many of the devices furnished by manufacturers are open to objection on the score of high cost, limited adaptability, and complicated mechanism. The two illustrated herewith are practical machines, which have been installed by home talent and have stood the test of long operation. The first, illustrated in Fig. 1, 2, and 3, samples the tailing from the Ymir mill, in British Columbia. It can be described as follows: *A* is a vertical chute down

shaft *G* and held vertical by an adjustable weight *H*. The crank, through its connecting rod and fork *I*, causes *D* to swing back and forth through the stream of tailing. The operation is as follows: When the water dripping from *F* has reached the proper point, it overbalances the counter-weight *H*, and *E* turns down toward the left, spills its water into the housing *L*, and is carried around by its inertia to its original position, raising the latch *N* as it passes and then falling back against it. By adjustment of *H*, this can be made to happen with little jar. It is easy to regulate this device to take samples from five minute intervals up to 30. *B* and *E* are the ordinary 5-gal. coal-oil cans of commerce. It should be noted that in Fig. 3 the actuating device has been omitted, and in

Fig 2, the apron *M*. The other device is installed at the cyanide plant of the same company. Here *A* (Fig. 4, 5, 6,) is the tailing chute and the sampling box *B* is suspended in the same way as before, with the exception that the hanger is bent from a single piece of iron; this construction is demanded because the connecting rod *I* works only on one side. The actuating device is a flutter wheel *G* in the tailing-launders driving the grooved wheel *E* through the medium of a crossed cord. Hanging loose of the shaft of *E* is a heavy arm of iron *C*, connected by *I* to the sampling-box. The pin *D* carries *C* around with *E* until it reaches the position shown in Fig. 4. From this position *C* falls by its own weight to its lower position, swinging the sample-box through the stream. In the lower position it remains

Freaks of Earthquakes.

From the MINING AND SCIENTIFIC PRESS, April 16, 1864.

The phenomena attending earthquakes, says an article on 'The God of Earthquakes,' in the London *Spectator*, are more apparently preternatural than those of any other human event. The ground assumes the appearance of running water, indeed, does transmit tidal waves as distinctly as the ocean itself. Not only are valleys exalted and hills made low, but nature appears to be working out on an awful and tragic scale the wonders of a pantomime. After the great earthquake of Quito in 1797 many whom the earthquake surprised in the town of Riobama were found as corpses on the top of a hill separated by a river from the place, and several hundred feet

Another Sampling Device.

until *D* catches up with it, when it is carried around again to the upper position. During this movement it swings *B* back still further out of the stream. This is a very pretty mechanical arrangement and works admirably. The use of the flutter wheel is, however, open to objection in that the time interval at which the sample is taken varies somewhat with the quantity of pulp passing. Assume that half the mill is hung up; if under this condition the wheel *G* revolves half as fast, the sample interval will be doubled, and as there is but half as much tailing dropping from *A*, the amount of sample taken for this period will be one-quarter of normal, when to give true results it should be one-half. With half the flow, no doubt the wheel *G* would not slow down to the same extent, but it would slow down slightly, and observation of the sampler in operation shows this to be the case. Moreover under the best of conditions the speed of *G* is not uniform, so that a better arrangement would be to have *E* actuated through the medium of some reduction gearing from the mill-shafting or from a water-wheel driven by a stream that can be regulated.

higher than the site of the town. The place was shown to Humboldt where the whole furniture of one house was found buried beneath the ruins of another, and it could only be accounted for by supposing that it had sunk into the earth at one spot and been disgorged at the other. In Calabria, in 1783, whole estates were literally shuffled, so that a plantation of mulberry trees was set down in the middle of a cornfield, and a field of lupines was removed into the middle of a vineyard. For several years after, lawsuits were actively carried on in the courts of Naples to reclaim landed property thus bodily conveyed, without legal forms, from one to another. Who can wonder that people who thus see what Englishmen emphatically call real property flying like shadows before their eyes, prostrate themselves before the great Earthquaker, in paroxysms of fear and superstition?

COPPER melts at about 2,000° F. or 1,093° C. When it is heated within two or three hundred degrees of its melting point, it becomes brittle and friable, and may be actually pulverized.

Contact Metamorphism in Its Relation to Ore Deposits.

By JAMES PARK.

¹A molten magma tends to effect changes in the rocks with which it comes in contact. In the case of overflow magmas the thermal changes are generally trifling, and in many cases hardly appreciable. Even magmas that have cooled in rents in sedimentaries at shallow depths have not always caused great changes in the enclosing rock.

The greatest alteration will naturally take place in the case of magmas that do not reach the surface, but cool slowly under great pressure. The greater the mass of the intrusive magma, the slower will be the rate of cooling; and the slower the rate of cooling, the longer will the adjacent rocks be heated. The rate of cooling will be mainly dependent upon the mass of the intrusion, the distance from the surface, and the relative thermal conductivity of the adjacent rocks.

The changes effected in the country-rock by the intrusion of the igneous magma will be mechanical and hydrothermal. The intruded sedimentaries will be compressed, bent, and more or less shattered and fissured along the line of intrusion. The magma will part with its heat by slow radiation into the adjacent rocks. The magmatic steam and gases, together with the gases generated in the sedimentaries,² will pass into and permeate the latter, and cause a molecular rearrangement of the constituent minerals, resulting in what is termed 'contact metamorphism.' As the igneous magma and the heated sedimentaries cool they will contract in area, and when the temperature normal to the depth has been reached the contraction will tend to cause the two rocks to shrink from each other, resulting in the formation of cavities along the line of contact.

Above a temperature of 365° C., and a pressure of 200 atmospheres, water and all more or less volatile compounds will exist as gas. Aqueous vapors above the critical temperature and under great pressure will act as strongly upon the cooling magma as upon the adjacent rocks. They will possess a solvent power which will be greatest at the depth where the highest temperature and pressure are reached. The pressure will cause the heated steam and gaseous emanation carrying the heavy metals to permeate the bedding-planes of the sedimentaries, and fill all accessible cracks and fissures. In this way bed-impregnation may be effected, and even orebodies formed at points some distance from the genetic eruptive magma. A decrease in the temperature and pressure will cause the least soluble substances to be deposited; and as the temperature and pressure continue to diminish, the dissolved substances will be thrown out of solution in the inverse order of their solubility. It is manifest that the later phases of the eruptive after-actions will represent in a modified form the waning effects of solfataric action. The deep-seated conditions will also favor the action of metasomatic processes in the zone of metamorphism, and veins will be formed, some of which may rise to the surface. It is probable that the circulation of the heated mineralized solutions in the later phases will tend to effect a redistribution of the ores and minerals deposited in the earlier stages. In some cases the ascending waters and gases may reach the zone of surface circulation and mix with the meteoric waters, which will then reappear

as hot springs, forming orebodies and veins not directly in contact with the eruptive magma.

Weed and some other writers have made an attempt to subdivide contact-metamorphic deposits into groups depending mainly upon the mode of occurrence. But the form and mode of distribution may be due to accidents of density or porosity, composition and hydrous condition of the rocks affected, rather than differences in genetic formation. Moreover, the mass of the magma, the weight of superincumbent rocks, the amount of heat and subsequent contraction, and phase of the after-action are all doubtless contributing factors in connection with the form and distribution of the heavy metals. Masses of ore occurring as contact deposits, fissure-veins, and bed-impregnations in the zone of metamorphism may all be traced to the same genetic causes.

De Launay supports the views of the school of De Beaumont and Daubrée in respect to the primary influence of volatile mineralizers emanating from eruptive magmas. The emanations, he contends, must have prepared the way by introducing into the enclosing rocks, or simply by depositing in the vein-fissures, elements such as sulphides, fluorides, chlorides, etc., which, subsequently dissolved anew by the circulation of superficial waters, have rendered the latter essential aid in the processes of alteration.³

The extent of contact metamorphism effected by the granite intrusions of Albany, in New Hampshire, was fully investigated by Hawes.⁴ His analyses showed a progressive series of changes in the schists as they approached the granite. The rocks are dehydrated, boric and silicic acids have been added to them, and there appears to have been an infusion of alkali on the line of contact. He regarded the schists as having been impregnated by hot vapors and solutions emanating from the granite.

Contact deposits frequently lie at the boundary between the eruptive and the country-rock; also at variable distances from the eruptive, but never outside the zone of metamorphism. More particularly, contact ores occur in limestones, marly and clay slates, and are accompanied by the usual contact minerals, garnet, vesuvianite, scapolite, wollastonite, augite, mica, hornblende, etc., and in clay-slate by chiastolite, etc. Contact ores are principally magnetite and specular iron, but sulphide of copper, lead, and zinc often occur. Pyritic contact deposits are typically represented by those of Vegsnas, in Norway; Rio Tinto, Tharsis, and San Domingo, in Spain.

The pyritic ore-mass in Mount Lyell mine, Tasmania, is generally described as a contact deposit, although its geologic occurrence does not strictly conform to the common definition of such a body. It is a boat-shaped body lying between talcose schists and conglomerates.⁵ The mine-workings have shown that it gradually tapers downward from the outcrop, being cut off below by a great thrust-plane. There are no eruptives in actual contact with the orebody, but dikes of diabase and other igneous rocks occur in the district at no great distance. The existence of these dikes and of bands of schist impregnated with sulphides forming fahlbands would lead to the belief that there at one time existed channels of communication leading from the eruptive rocks to the vein cavities. It seems probable that the orebodies in the Mount Lyell field were formed in the later or solfataric stages of eruptive after-actions.

Among the ore deposits genetically connected with eruptive after-actions Vogt⁶ includes cassiterite and apa

¹From *The New Zealand Mines Record*. Abstract of paper entitled 'Contact Metamorphism in Its Relation to the Genesis of Certain Ore Deposits' by Professor James Park, Director of the Otago University School of Mines, New Zealand.

²Professor Joseph Barrell has shown that the heat of an igneous mass acting upon sedimentaries liberates enormous volumes of steam and gases, attended by a shrinkage of volume of the rocks and the formation of vein-fissures: 'The Physical Effects of Contact Metamorphism.' *Am. Jour. Sci.*, Vol. XIII, April, 1902, p. 279.

tite veins and "ore-deposits of contact-metamorphic zone." Cassiterite deposits are everywhere connected with acid eruptives, principally granite, and occasionally quartz-porphyry and rhyolite. Partly for this reason, and partly because of the characteristic paragenesis of fluoride, borate, and phosphate minerals, he supports the common view that tin deposits are genetically connected with granitic eruptions, and that various volatile fluorides took part in their formation. Cassiterite veins were formed, he thinks, by pneumatolytic processes⁷—that is, by the action of gases and water at high temperature and pressure. He further urges that they were formed immediately after the eruption, and before the complete cooling of the granite, one proof of which is the occurrence of tin-vein minerals in veins of pegmatite in the granite.

Cassiterite veins are admittedly independent of the immediately adjacent country-rock, and for this reason seem to be more nearly related to deposits of magmatic segregation than to contact-metamorphic deposits.

It is probable that the magmatic segregation of chromite in peridotite was in some cases effected by pneumatolytic agencies before the complete cooling of the magma. It is not uncommon to find chromite in vein-like masses that have the appearance of having been segregated in cavities of contraction in the pasty magma. As the agency of underground water cannot have been active in this class of ore deposits, the aggregation must have been effected by metal-bearing steam and gases occluded in the igneous magma.

Pegmatite veins, while genetically connected with granitic eruptions, seem to be of later formation than the cassiterite veins. They often pass into quartz, and frequently possess sharp well-defined walls, which suggest their formation in shrinkage cracks by pneumato-hydro-genetic agencies in the waning phases of the after-actions developed by the progressive cooling of the eruptive magma. The different phases of after-action must necessarily merge into each other, and hence we may expect to find, as we do, tin-vein minerals and even cassiterite in veins of pegmatite.

Among ore deposits of contact-metamorphic origin Vogt includes the orebodies which occur within the metamorphosed contact zone of deep eruptives, especially granite. He distinguishes several types of contact deposit. The Christiania type includes iron-ore deposits that appear to have been formed before the solidification of the granitic magma. These ores are never found in the granite, but always in the adjacent rocks. If they had been introduced after the cooling of the magma they would also have been deposited in the granite. The eruptive magma is believed to be the source of the metal, which is expelled in the heated steam into the surrounding rocks.

The synthetic experiments of Daubrée seem to justify the views of Vogt, Beck, and other observers that cassiterite and pegmatite veins are formed by gaseous and aqueous emanations, and not by direct segregation.

PYRRHOTITE, according to Brogger, appears abundantly in altered rocks, and is certainly a mineral formed during the contact-metamorphism, for it does not occur in unaltered rocks. It is not easy to say whether an addition of material has really taken place, or the mineral represents a recrystallization of finely distributed pyrite. Strongly in favor of the hypothesis of direct addition is the fact that large accumulations of pyrrhotite exist in the contact-metamorphic rocks—so large, indeed, that mining has been attempted in places.

Cheap Mining and Milling in South Dakota.

Written for the MINING AND SCIENTIFIC PRESS
By E. J. KENNEDY.

The Golden West mine, situated six miles southwest of Rochford, is equipped with one 6-ft. Chilean mill, with a capacity of 100 tons per 24 hours. Water-power is obtained from Castle creek through a flume 8,425 ft. long, having dimensions of 30 by 40 in., and a pipe-line 26 in. diam., 2,740 ft. long, with 123 ft. net fall; this furnishes 500 h.p. There is an aerial tramway one-half mile long, connecting the mine to the mill; the tram buckets dump into a large crusher and the mill is all built on the gravity plan. One man runs the whole mill on the day shift and another does it at night. There is one man at each end of the tramway. Four miners and one hoisting engineer work from a glory hole, so that the whole cost of mining, hauling, and milling this season runs a fraction under 50 cents per ton. A large body of ore and of slightly better grade was opened up this summer east of the old workings. A glory hole 60 ft. across in every direction and 30 ft. deep has been opened up and still has the same grade of ore on all sides and at the bottom.

Our Chilean mill has not proved satisfactory as an amalgamator, the saving being about \$1.50 and the loss in free gold \$1.20, besides about \$0.80 in refractory material, which yields 85% in 72 hours by cyanide treatment. Our plans for the future are to shut down this month and commence the work of reconstruction for next season by installing three Chilean mills of the Lane type, namely, 10 ft. diam., the six rollers making 10 rev. per min.; these mills to take the product from the Chilean mill we have now.

After the ore has passed through two crushers, we shall use screens with $\frac{1}{4}$ -in. holes on our 6-ft. mill, with low discharge, running about 150 tons per day through it and distributing 50 tons to each Lane mill, where we expect to amalgamate at least 80% in the mortars. We find, after four years' experimenting with Chilean mills, that our ore needs fine grinding and much polishing to amalgamate well, and that a Chilean mill will do this, but it must have slow speed, high discharge, and the screens must not be too close to the wheels, nor the wheels too heavy, and the product must be fed to the mills at about $\frac{1}{4}$ -in. size, to do good work. The wear on steel, so far, in our Chilean mill, has been 2.3c. per ton of ore.

We shall then put in a Dibble slime separator, a new invention just out and patented by H. D. Dibble, of Mystic, South Dakota, by which the slime will be run off, being of no value, and the sand and coarser material will be cyanided, which means cyanidation of about 30% of the whole product as the ore runs now; but with greater depth the slime will be less and the concentrate increasing. We shall install a boiler and engine next fall for winter use, that is, during the four months when the creek runs to slush and ice; this, however, will not be very expensive in our case, as wood is plentiful close to the mill and there is enough of it to last for many years.

THE minute difference of 0.006 between the weight of a litre of atmospheric nitrogen and that (1.251) of chemical nitrogen led Lord Rayleigh and Sir William Ramsay to the discovery of a new element, which in turn led up to the discovery of others of perhaps greater importance. That a change in the third decimal should lead to such brilliant discoveries tends to show, not only the accuracy of modern scientific investigation, but also the wide field available for original chemical research, leading, doubtless, to the discovery of many new and possibly much needed elements.

⁷Pneumatolysis is a term first used by Bunsen to describe the combined action of gases and water.

Copper Mining in Nevada.

By MARK L. REQUA.

*Ores that today present no difficulties from a metallurgical standpoint, twenty years ago were absolutely valueless. The conditions of today have been brought about by the experience that has been gained from the operations in the great copper camps of the West during the past decade, from Montana to Arizona, and from Utah to California. Had the problem that was presented to me on my first visit to this district been presented even five years previous, its solution would have been considered hopeless—in fact, I may say that the problems surrounding the working of these very low-grade ores have only been worked out satisfactorily within the last two years; and it is due to the Bingham district of Utah, more than to any other, that we have today absolute data based upon actual work, rather than empirical estimates.

The metallurgy of the high-grade gold and silver ores was successfully worked out upon the Comstock, and the smelting of lead ores at Eureka, but for the metallurgy of copper we must first of all turn to Montana, where the high-grade ores of Butte permitted extensive experimenting, the results of which have revolutionized the copper industry of the world. From Montana to Arizona, through the camps of Bisbee, Clifton, Morenci, and Globe; also at Granby, in British Columbia, and at Bingham, all with their varying problems, both of local environment and different mineralogical conditions, the metallurgy of copper has been worked out from the high-grade smelting ore, both oxide and sulphide, to the lean concentrating ores that are characteristic of Ely, and that are found in identical occurrences at Bingham and the Clifton-Morenci district of Arizona.

Fortunate, indeed, has it been for the West that the great deposits of high-grade ore yielded not only a profit with what now appears to have been the crudest of metallurgical appliances, but also permitted of extensive experiments, which, in their sequence, have made possible the profitable exploitation of low-grade bodies that bid fair in ultimate production to surpass the high-grade districts. Few people realize the evolution that has been taking place in the copper industry of the West during the past two or three years. The low-grade porphyry deposits which are being exploited at Bingham and Ely have come to be looked upon as the future source of the great copper output of the West, and, owing to their enormous tonnage, it is possible to forecast their production far beyond the life of the present generation.

It would be the height of folly to say that the methods of handling these ores have been perfected. We are today confronted at the first step of our process with a loss of from 15 to 20%, which is carried away in the tailing from our concentrators. I know of no field so promising for the winning of a large fortune as the perfecting of some method whereby the loss in concentration may be eliminated, or at least largely reduced. The smelting processes are much nearer perfection, but, with all that, it is safe to say that the plant which we are going to erect for the treatment of these ores will, within ten years, be obsolete. In fact, I believe that we shall, within five years, see changes that will materially alter our process in some of its most vital points. We are, however, building here at this time the very best plant that the combined knowledge of modern copper metallurgy is capable of producing, and I can say without fear of contradiction that, when finished and in operation, it will be the most modern and economical copper reduction plant in the world.

The task of bringing this undertaking to successful fruition has not been an easy one. On my first visit, I saw only the signs of repeated failures; the efforts that had been made to wring profits from the rocks had been without success and my first day's inspection convinced me that, if there was to be success, it must be along lines radically different from those that had already been tried. After a week's study, the problem had resolved itself to a very simple one, save for the unknown factor that must be supplied in order to make the problem susceptible of solution. I saw before me a mineralized zone wherein the question of tonnage had even at that time, to my mind, been entirely eliminated. The unknown coefficient for which I was searching could only be determined by extensive development work; that coefficient was the average copper content of the porphyry in large masses. I had seen upon the surface streaks of high-grade ore that in themselves were interesting, but which did not hold forth prospects of a tonnage sufficiently large to justify the expenditure that I knew must be made in order to put the copper into marketable form. I saw in those early days that the only hope for this district was in developing tonnage of such magnitude and value as would justify the building of a railroad from the Southern Pacific. This meant the building of a line approximately 150 miles long, to justify which would require the development of millions of tons of copper-bearing ore. I had crawled down the Ruth mine 300 ft. on the incline and seen 40 ft. of a cross-cut that averaged approximately three per cent, with apparently no end in either direction. I had seen this same porphyry upon the surface leached of its copper, extending for hundreds of feet in width, and I knew that underground development would reveal enormous masses of this material, but I did not know what the copper content of it would be. It was, therefore, necessary first to develop this ore and determine its value not only sufficiently to justify the building of a railway, but sufficient in quantity to justify an enormous reduction plant, because profits could not be hoped for unless the ore was handled by the thousands of tons per day. Over a period of two years this prospecting work was carried on until a large tonnage of ore was developed. Even then, the railway was not justified, because there was no certainty as to what could be done with the ore in concentration. To determine this factor, a small experimental mill was built at the Ruth mine, which was operated during a period of three months, and most exhaustive tests and determinations made. The entire mine, in fact, was sampled by means of this mill; the results were compared, tabulated, and carefully scrutinized. That these results were satisfactory, is proved by the building of the Nevada Northern Railway, which was undertaken immediately after these mill-tests were completed.

In the meantime there had been effected the consolidation of the New York & Nevada and the White Pine properties under the name of the Nevada Consolidated Copper Co. At Copper Flat we had not been idle and the tonnage developed at Ruth is more than equaled by the tremendous body of ore at the Flat, whose limits have not as yet been defined. I think you will agree with me that we were justified in suspending development work, when I say that there is developed at Copper Flat and at Ruth ore sufficient to supply this reduction plant for at least ten years, with the largest part of our ground still unprospected, but giving every evidence of containing ore similar to that we have already developed. It was to meet this situation and afford means for working this ore that the Nevada Northern Railway was built.

PROCLAIM human equality as loudly as you like, Witless will serve his brother.

*Abstract from an address delivered at the driving of the last spike of the Nevada Northern Railway at Ely, on September 23, 1906.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

MINING-MACHINE.—No. 831,516; Charles Mead, Murray, Idaho.

In a machine of the class described, a frame, a lever fulcrumed thereon, a rigid striking-arm pivoted to said lever and supported thereby, a drill fitted to the striking-arm for movement with the same, and means operating through the lever for holding the striking-arm and the drill in working positions.

ORE-SIZING SCREEN.—No. 831,681; Clarence E. Ratcliff and Jacob A. Cohenour, Salem, Kentucky.

In an ore-sizing screen the combination with a plurality of rigidly connected screens, and means for vibrating them in unison; of a rotatable ratchet-wheel, means for holding the wheel against movement in one direction, a lifter extending from said wheel, a spring-pressed rod disposed adjacent the wheel and springs, a toe extending from said rod and into the path of the lifter, hammers extending through the rod and above, and adapted to strike, the screens, and means actuated by the vibration of the screens for rotating the ratchet-wheel to trip the toe and hammers after a predetermined number of vibrations.

MINING-DRILL.—No. 831,056; Benjamin V. Gilmore, Red House Shoals, West Virginia.

A hollow tubular mining-tool, a cutter detachably fitted to an end thereof, an inner cutter and a pin for securing the inner cutter in place and in turn prevented from displacement by the said removable end cutter.

ROASTING-FURNACE.—No. 831,165; Frank Klepetko, New York, N. Y.

In a rabble apparatus, a hollow shaft and hollow arms therefor, a feeder passing centrally through the shaft and discharging a cooling medium thereinto at one end of the shaft, and means for circulating said medium through the shaft and arms vertically in series, and radially through a multiple, substantially as set forth.

PROCESS FOR THE ELECTROLYTIC PRODUCTION OF COPPER.—No. 830,639; Johannes A. W. Borchers, Aachen, Paul R. Franke, Eisleben, and Franz E. Gunther, Aachen, Germany.

The process for the direct electrolytic production of pure copper from copper matte which consists in first bringing the copper matte to a richness of between 72 and 80% of copper, and then using said matte as an anode in an electrolyte composed of an acid solution of copper sulphate.

ORE-SLIMER.—No. 832,091; William F. Smith, Whitecross, Colorado.

In an ore-slimer, the combination with a receptacle for dispensing ore tailing, of a series of slime-filters made up of intermediate boxes having outlet openings in their walls, removable screens mounted within said walls, means for binding the screens in place, and an end filtering-box having liquid outlets in its walls and side and end inclined screens converging upwardly and arranged to intercept the liquids as they pass out of said end box.

ORE-CONCENTRATOR.—No. 830,425; William E. Ford, Carthage, Missouri.

In a mechanism of the class described, the combination with a reciprocating bed, means for reciprocating the bed, said means comprising an unbroken rock-shaft, a crank carried by the rock-shaft, a curved link pivoted to said crank and disposed with its concave side toward the said rock-shaft and being arranged to receive the said shaft in its concavity and connections between the said link and the bed to reciprocate the latter when the crank is rocked, said crank being arranged to extend when at the limit of its movement toward the bed, at a lesser angle to the plane of movement of the bed than when the crank is at the limit of its movement away from the bed.

Repairing a Cracked Cylinder.

The method of making the repair was as follows:

1. While the cylinder was hot a partial vacuum was created in it and Smooth-On Elastic Cement was painted over the crack. The vacuum drew the cement in, and this operation was continued until the crack would take up no more cement.
2. Holes were then drilled and tapped at the end of the crack, *D* and *E*, and bolts put in to prevent a further extension of the crack.
3. The patch was cut as represented on the accompanying illustration.
4. The crack was then painted with Smooth-On and the

Repairing a Cracked Cylinder.

patch laid in position. Then it was carefully removed. The imprint of the crack was now shown on the under side of the patch, the Smooth-On sticking to it. The patch was then dished along the line of the imprint to make a recess to hold sufficient cement.

5. The plate was then warmed and a compound composed of Smooth-On Iron Cement No. 1 and Smooth-On Elastic Cement, mixed half and half, applied to the warm plate with a small trowel, making a thin, even coating.

6. Then the patch was laid in position. The three centre bolts, *A*, *B*, and *C*, nearest the crack were brought up, just taut. Then the outside bolts were brought up tight, and lastly, the three centre bolts were brought up as tight as possible, which forced the cement into the crack. The steam was turned on and the crack was tight.

Air-Compressor Lubrication.

Some time ago in the course of an article on 'Temperatures in Air and Ammonia Compressor Cylinders' which was published in *The Engineering Magazine*, Mr. Leicester Allen wrote: "One of the dangers in air compression which has not been fully recognized until quite a recent period is the liability to explosion in air-compressor cylinders when the heat of compression is caused to exceed the flashing point of the oil used for cylinder lubrication. Several more or less serious accidents of this nature have been recorded within a period of three or four years." Another writer, Mr. Alex. M. Gow, in the *Engineering News*, said: "Ignitions and explosions in the discharge-pipes and receivers of air-compressors are by no means uncommon, and for very obvious reasons the manufacturers say as little as possible about the subject to prospective buyers. It cannot be expected that the men in charge at the time of accidents will make any report that will reflect upon themselves. So it happens that in but comparatively few cases of these accidents have the results of careful investigation been given to the world at large." The matter is nevertheless brought up for discussion from time to time in engineering papers, and the facts presented strongly emphasize the

necessity for a clearer understanding of conditions and causes of explosions in compressed-air systems on the part of those operating them. The causes of ignitions and explosions in discharge-pipes in air receivers and the function and the value of Dixon's Flake graphite as an air-cylinder lubricant from the theoretical as well as the practical standpoint is very fully and fittingly set forth in an entirely new pamphlet issued by the Joseph Dixon Crucible Co., of Jersey City. It is entitled 'Air-Compressor Lubrication.' Manufacturers of air-compressors and users of compressors, drills, and all compressed-air apparatus will be on the wise side if they send for a copy of this pamphlet.

Commercial Paragraphs.

THE RISDON IRON & LOCOMOTIVE WORKS has issued Bulletins No 19-1 and 19-2, describing the silver-lead and copper blast-furnaces which this company manufactures.

J. H. ELLSPASS, of the Ellspass Engineering Co. and Samson Mfg. Co., is making an extended trip to Pittsburg, New York, and other Eastern cities, on business connected with his companies.

THE RIX COMPRESSED AIR & DRILL CO. is now occupying new offices at 219-221 Spear St., San Francisco. The factory, warehouse, and branch office are at 1436 Fifth St., Oakland, between Centre and Cypress Streets.

THE HENDRIE & BOLTHOFF MFG. & SUPPLY CO., of Denver, has issued catalogues describing the Dorr classifier and the Card concentrator. As both of these machines are winning favor among millmen, the descriptions given in these catalogues ought to prove useful.

A. MERLE & CO., successors to San Francisco Novelty & Plating Works, have completed their office and factories at Bay and Stockton St., San Francisco. This firm, established in 1865, claims to be the largest manufacturer of silver-plated copper amalgamating plates in America.

THE CROCKER-WHEELER Co., of Ampere, N. J., has shipped within the last few days nine carloads of electrical machinery exclusive of other smaller shipments to the following large concerns: The National Tube Co., the Lehigh Portland Cement Co., the Snow Steam Pump Co., the Crocker-Wheeler Co., at San Francisco.

THE CHICAGO PNEUMATIC TOOL CO. announces that it is enlarging its machine-shops to increase its output from 55 to 70 compressors per month. An interesting pamphlet just published by the company shows that the compressors, 1,000 of which have been turned out in the last three years, are finding world-wide appreciation.

THE CROCKER-WHEELER Co. announces the following sales: To Armour & Co., South Omaha, Neb., 6 Form I motors, 230 volt, shunt wound; to the Salt Lake Hardware Co., Salt Lake City, Utah, two 50 k. w., 125 v., D. C. generators, driven by Ball engine; to the Colorado Iron Works Co., Denver, Colo., 4 motors, 230 v., shunt wound, and one 40 k. w. generator, 250 volts.

THE BUFFALO FORGE Co. is bringing out new designs of forges with its characteristic initiative. The light and inexpensive hand-blowers are well known for their power and durability. An attachment by which a tiny jet of compressed air may be made to impinge on the fan blades, causing them to revolve and draw in a volume of air very much larger than that of the compressed air used, is an interesting feature of new designs.

HENSHAW, BULKLEY & Co., the well-known machinery house of San Francisco, whose offices were formerly located at the northwest corner of Fremont and Mission streets, is now at 219-221 Spear street, near Howard. The new offices are well appointed and each department is provided for in a spacious and well-lighted room. The firm extends an invitation to the general public, particularly that part of it interested in machinery, to visit the new offices. Within the past few months this company has established sales offices and warehouses in the cities of Los Angeles and Oakland.

Editorial.

THE PURCHASE of the control of the Nipissing mines at Cobalt by the Guggenheim Exploration Company is an important event and will draw further attention to that most interesting district in northern Ontario. The veins are characterized by high-grade silver ore, with pockets of the native metal. At the recent high price of \$34 per share, the property represents a market valuation of \$40,800,000.

SPEAKING OF COPPER, the high price of the metal and the speculation in the shares of copper mining companies are stimulating prospecting to a notable degree. The Greenwater district, just over the Nevada line and in Inyo county, California, is being greatly boomed, but there is substantial basis for it. Some fine bodies of ore have been uncovered there. It appears also that in the Gore range, in Colorado, near the line of the new Moffat railroad and on the west slope of the Rocky Mountains, an important find of copper ore has been made. Colorado produces but little copper and any large output would be important, especially from a smelting standpoint.

ON ANOTHER PAGE we publish an earnest plea for the better recognition of the value of geology in mine development. We are glad to give Mr. John A. Reid space for his statement of the case. Others may wish to discuss the matter. Certainly, the application of geology has made great strides in an industrial, as well as a scientific way. Geologists experienced in the structure of ore deposits are in demand among mine operators. We may instance the cases of W. F. Ferrier, Walter P. Jenney, J. E. Spurr, H. W. Turner, Horace V. Winchell, and others, who, as specialists, are regularly retained by important financial organizations to give advice on the exploration and development of mines. It is a pity that the increased appreciation of the importance of this branch of mining engineering should have taken away from the Geological Surveys of the United States and of Canada several able scientists, but it is the inevitable result of governmental parsimony as compared to industrial exuberance.

A JUDGE OF the Superior Court of Solano county has granted an injunction against the Selby Smelting & Lead Co. at the instance of Solano county. It is his opinion that the fumes hurt the health of the people on his side of the water more than that of those on the Port Costa side. It seems anomalous that a case brought by the farmers of Solano county should be tried before a judge elected by the farmers of Solano county. However, the judge counseled the plaintiff to be gentle in enforcing the injunction. Meanwhile, we also venture to recommend the farmers to be reasonable, and suggest that they take note of the action of their co-agriculturists in the Salt

Lake valley, who have reached a settlement with the smelters in that thriving region. And it thrives, not only despite the noxious fumes of sulphur and arsenic, but by reason of them. Smelter smoke makes farmers fat, if they did but know it. It is the sign thrown across the heavens to signal the prosperity of an industry that gives the farmer the best market for his produce. The Salt Lake valley is rich today because the surrounding mountain region contains active mining communities that consume agricultural products. Wherever the smelters are willing to pay for actual damage done to adjoining land or cattle, we hope public opinion will resent any attempt to blackmail them. A big industry must not be side-tracked to please a few cows. In the meanwhile metallurgists will do well to improve appliances for condensing fume and collecting flue-dust, to the end that any injury may be minimized.

Make-Believe Reformers.

The decisive defeat of W. R. Hearst should encourage good citizens and warn pseudo-reformers, who make noises only, like coyotes before the dawn. We suffer from piracy in finance and corruption in municipal government, but we suffer also from insincerity of purpose among those who pretend to make it their business to correct existing evils. Two men have become famous or infamous—as you will—by their attempts to excite resentment against those who are dominant in business and politics. We refer to Thomas W. Lawson, of Boston, and W. R. Hearst, of San Francisco and New York. For Lawson we have some respect; for Hearst none. Lawson did good service in exposing the ways of low finance, and he did it with a literary skill that made the performance artistic. He gained a wide hearing even among thoughtful people, for his raciness of diction and command of slang, his intimate knowledge of the ways of Wall Street, and of the honor that obtains among thieves, give his writings the value of a chronicle of the time. To his credit belongs the exposure of the insurance companies and the better recognition of the fast-and-loose methods of predatory promoting. If he had been sincere, he could have formed a party and led a reformation; but he was not. In the very midst of his crusade he worked a small game; he played the stock market and took advantage of his notoriety to invite inexperienced speculators to entrust their money to him. The crusade became a farce. He proved himself a sham; a brilliant pamphleteer, but a small man. The cause of real reform was flouted. But irresponsible, pyrotechnic, and insincere as he is, Lawson aroused none of the disgust that Hearst has stirred across the entire continent. He throws a spadeful of garbage every morning into the faces of the citizens of New York, Boston, and San Francisco, and he calls it journalism. Heaven forbid! Journalism is what Franklin founded, what William Lloyd Garrison and Horace Greeley honored, and what Hearst has only prostituted. It has been his particular function to prove how powerful the press is—for evil. It has been given to him to demonstrate what foul anarchy can be stirred by those who masquerade as statesmen. It has been permitted to him to show how

men of vile character may by force of native intelligence and the power of inherited wealth, so deceive a large portion of the unthinking voters as to be nominated for a high office. And it would be a dark outlook, indeed, if we were not able to record this week that he has been taught a lesson so severe as to make another unnecessary.

We need reform and we need reformers, but not so badly as to follow the leadership of insincere spoofers like Lawson, or unprincipled demagogues like Hearst. And it is a thousand pities that at a time like this the effort to check corruption in public office, in commerce, and in finance should be discredited by the assumed guidance of such men. We need character in our leaders, fixity of purpose, and sincerity of mind, strong men in a time of blatant talk. The election in New York demonstrated the force of such a man. When the President told the people of his State just what he thought of Mr. Hearst, the effect was at once apparent; a man of character flattened out the man of no character. Mr. Roosevelt does many things in a hurry, some of them injudicious; he takes himself a little too seriously, as if lacking a sense of humor in important affairs; nevertheless, it heartens the essential manhood of the country when he comes out squarely for right-doing and right-thinking. Lawson is but a clown in the circus of down-town finance; Hearst, the man-hole of a sewer. No good can come to a good cause when led by such as they.

A Mining Exchange for New York.

Interest in mining speculation has grown exceedingly during the last three months. The volume of trading in stocks on the New York and Boston curbs has assumed surprising proportions, and it has received the attention of some of the best Stock Exchange brokers. On Broad Street the sales have aggregated a million shares per week and on single days the total has been known to exceed 300,000 shares. There have been some spectacular rises; for instance, Nipissing has risen since August 13 from 5½ to 34, the par value being \$5; Cumberland-Ely has jumped from 7½ to 14½; Giroux Copper from 7 to 14½; and there are other cases, such as Nevada Consolidated which was lately \$22 and was \$36 a little over a year ago. Naturally these tremendous advances have made fortunes for many men, and in several cases the rise has been amply warranted by mineral discoveries of unusual richness or extent. The result has been to create wide interest in other low-priced mining stocks and to stimulate the speculative activities of those who play with money. As viewed from a distance, the large operations on the curb emphasize once more the need of a properly organized and respectable mining exchange. Such an institution, while affording better facilities than the peripatetic concourse in the open air that now does duty for a mart in New York, would permit of some regulation of the business and a control over the doings of irresponsible people. As it is, every boom on the curb is followed by a scandal, disclosing washed sales, disreputable promoters, and unhappy dupes. Such episodes hurt the real business of buying and selling of shares in profitable mines and legitimate ventures. Without properly constituted authority, such a market as the curb is a menace to mining.

By the Way.

Mr. James Douglas gave a most informing address at Columbia University recently, on the relations of railroad transportation to mining and metallurgy. He said, in part:

The marvelous feats which two generations of engineers, in handling steam and electricity, have enabled us to perform, may not be duplicated by equal progress during the next half century; but it goes without saying that but for our transportation facilities we would not occupy in the world's race the same advanced position we have acquired today, for the very vastness of our country, and the actual distance, from one another and from population of our resources, would have rendered many of them valueless. But, given control of steam, the great size of our mineral deposits and the long distance our continental areas require that we transport material, has inspired our transportation engineers to work on a larger scale than their fellow craftsmen across the sea. We handle longer trains, with larger cars, and as a rule at a much lower rate of freight than they do. Otherwise, neither our miner nor our metallurgist could perform the duty required of them.

Take, for instance, the cost of transporting a ton of iron ore from Lake Superior to Pittsburg: 70 cents from the mines to Duluth, a distance of 80 miles; 75 cents for 1,000 miles by steamer to Cleveland (though the rate has been as low as 57 cents, and though, when the first shipments were made from Michigan in 1856, the rate was \$3); then \$1.18 from Lake Erie points to Pittsburg, a distance of 135 miles—making the total transportation \$2.63 for 1,250 miles, including transfers.

Or take the \$10 rate at which copper is transported from Montana to the Atlantic, a distance of nearly 3,000 miles. Soft coal is carried by Eastern roads at about a half-cent per ton a mile, but the rate on some Western roads is as low as 40 mills per ton-mile. Nor is it only in the iron trade that low rates of carriage have helped us metallurgists.

The necessity of low fuel rates to economical metallurgy is obvious, especially when treating ores such as those of copper, whose percentage of valuable metal is so low that, even after water concentration, as many as twenty tons of charge are probably smelted on an average to yield one ton of copper. In such cases the fuel must be carried to the ore—not the ore to the fuel, as when smelting rich iron ores. At the Copper Queen works in the early days the cheapest coke was Cardiff Patent Pressed brought round the Horn in wheat ships to San Francisco. It costs more than three times the price at which New Mexico or Colorado coke is now delivered, after a railroad haul of from 800 to 1,000 miles. Coal for steam generation was then so costly that the country was swept clear of its scanty accessible forests. For raising steam crude oil is now brought in from Texas and California at a freight rate not exceeding three-fourths cent per ton-mile; so that at one smelting works in southern Arizona 700 miles away from the nearest coal, or available petroleum wells, power is generated at a cost for fuel, maintenance, and all expenses, of \$79 per ton per year. Montana draws its coke largely from Pennsylvania, or from coke ovens on Lake Superior, fed with Pennsylvania coal, the fuel traveling over 2,000 miles from the pits to the furnaces.

While complaint may be made against some railroads for charging exorbitant rates on coal, our Western roads are certainly not culpable, or Montana would not be able to turn out in metallic copper about one-fifth of the world's total, and Arizona about one-seventh of the world's total, though both are situated in the heart of a

continent, and between 2,000 and 3,000 miles distant from the point where their crude product is refined and marketed.

The interdependence of mines on railroads and of railroads on mines is best appreciated by some familiar examples of what each does. Butte, both the town and the great Butte mines, are situated on a mountain side facing a valley beneath whose surface water can be reached in any quantity and at all seasons only by wells, but where none flows. The two great corporations operating there have been obliged, therefore, if they were to concentrate mechanically their large tonnage of low-grade ore, to transport their ores to water. A site 26 miles distant was selected by the Anaconda Co., and thither to their new Washoe works are carried daily from Butte, of their own and custom ore, about 9,000 tons at a cost of about \$5 per car, or 14 cents per ton. As the ore contains less than three per cent of copper per ton and \$1.29 in gold and silver, a haul of that length would be profitable only if carried at such low rates of freight. The other large company, the Boston & Montana Co., sends its ores 170 miles to Great Falls, where, however, the company has the advantage of water-power.

An interesting instance of the facilities which transportation gives the metallurgist is afforded by the shipment of copper matte from Tennessee to the heart of Mexico, where it has been used to collect gold and silver from dry ores in the furnace and converter, and then returned for electrolytic refining and separation to the United States. Copper bars come from New Zealand to be refined here, and the refined copper is returned to Europe for consumption, for we ship abroad about 40% of our production. But for cheap carriage, often for long distances, of ore necessary to make a profitable mixture in lead and copper furnaces, many a district would be unexplored and unexploited. Till recently, for instance, the mines at Globe, Arizona, languished for want of sulphur and iron flux, and could barely make a million tons of copper per month. But the railroads, appreciating the needs of the miner, and appreciating what is their own true interest, published a low-ore tariff which enabled pyrite to be imported from distant districts where it is in excess; and as a result the production rapidly rose to three million pounds per month.

The copper industry, as compared with the iron trade, if gauged by the quantity of copper produced, is insignificant; but if measured by the ore raised in making a ton of copper, it assumed very different proportions. Instead of two tons of ore to the ton of metal, as in the case of iron, the average of ore mined, previous to water concentration, is more nearly 40 tons, and therefore there are handled, to make our 460,000 tons of copper, about 18,000,000 tons of ore. Though this is not carried the same distance that iron ore is carried to fuel, nearly all of it is moved by steam for a longer or shorter distance; and as about four tons of fuel are consumed to make one ton of copper, nearly twenty million tons of freight must be carried by the railroads to enable us to maintain our position in the copper world.

Our Western copper industry, like our iron industry, sprang into life at the touch of the railroad. Not until the Southern Pacific approached Arizona in 1880 was any notable copper made there, and the railroad alone galvanized Butte within a year afterward into activity. And today our increasing production of that much sought after metal is due either to railroad extension into new regions or to lower freight rates over existing railroads. For our railroads have been learning that their prosperity depends on the healthy growth of the industries along their lines, and that these industries can be starved to death by high freight rates, or fed into lusty vigor by encouragement.

Special Correspondence.

Johannesburg, Transvaal.

The Rand Has a Birthday.—Its Tumultuous Past and Agitated Present.—A Big Output.—Deep Levels in Trouble.—An Experiment With Cape Boys.—Labor Situation Bad.—More Diamond Prospects.

A few days ago Johannesburg attained its twentieth birthday, and the event was celebrated by the *Rand Daily Mail* with a special edition, reviewing the history and progress of this city during the past twenty years. It is a truly wonderful story. To build upon the bleak barren veldt a city like this, to inaugurate an industry that is producing over £2,000,000 worth of gold per month, is an achievement to be proud of. In reviewing the past, one is struck with the atmosphere of unrest that has prevailed. Johannesburg never seems to be at peace. There is always something to stir up the community, either a raid, a monopoly, a war, or anti-Chinese agitation. Give us peace, and the future of this place will be far greater than the past. Another phase that strikes the reviewer is the spirit of gambling that has existed and still prevails. The number of wild-cat schemes that have been promoted in the past is almost incredible. Today Johannesburg is having hard times, yet at a recent race meeting, there was a turn over of nearly £19,000. However, there is not a place in the world where mining is on a firmer business foundation than it is here. It is to be hoped that the days of the charlatan are over.

August proved a notable month so far as output is concerned, for the total of 509,115 oz. was a record output. The labor supply has not increased during the past month, so that the improvement is due to greater efficiency of the labor at work. The Chinese mines are making a fine showing. The coolies are well trained by this time, and are now excellent laborers. The highest crushing duty per stamp per 24 hours was made by the Luipaard's Vlei Estate, which returns a duty of 7.63 tons. The percentage of waste rock sorted out shows a considerable variation on the different mines. On the Consolidated Langlaagte there was no waste sorted, while on the Princess Estate 35.31% of the tonnage mined was discarded as waste.

The deep levels are beginning to feel the hard times rather severely. A meeting of the shareholders of the Vogelstruis Consolidated Deep, held a few days ago, shows the position of this half-developed mine to be rather desperate. Bantjes Deep has been placed in provisional liquidation, with a huge debt. It would be difficult to float a new deep level these days. In the past there has been no difficulty in getting funds, but now money seems scarce, as people are afraid of the future.

The native labor position is far from satisfactory. The ebb and flow of Kaffirs to the Rand is most exasperating. It is impossible to run an industry like this with labor as erratic as Kaffir labor. An experiment is being made with 'Cape boys' (half-caste laborers from Cape Colony), but these half-castes are not proving a success. They are more expensive than either the Kaffir or the Chinaman. The 'Cape boy' is a fairly hard worker, but as a rule he is rather a drunken rowdy specimen of humanity; the employment of him will certainly not solve our labor difficulty. The total number of coolies on the Rand on August 31, 1906, was 52,079. It is satisfactory to note that there have been no outrages committed by Chinese for some time past. It is probable that most of the bad characters have been weeded out. In a year's time the contracts of the coolies will begin to expire. One cannot

help wondering what will happen then. Take away the 52,079 Chinamen now at work, and the mines will be in a bad way. The failure of the 'Cape boy' experiment, and of the free recruiting for Kaffir labor, should prove to everyone the necessity of Chinese labor.

The boom in diamond prospects continues. How long it will last, it is hard to say. If the numerous diamond syndicates collapse, it is probable the gold shares will be affected also.

Salt Lake, Utah.

New Companies Organized.—Big Orebody In the Cactus.—Deep Creek District Reviving.—The Ontario Adit.—Shipments From Tintic.—Increased Local Activity.

The shareholders of the Big Cottonwood Copper & Gold Mining Co., operating in the Big Cottonwood district, near Alta, have authorized an increase of capital stock from 300,000 to 750,000 shares of \$5 each. N. Treweek, of Salt Lake, is president. — The organization of the South Columbus Con. has been effected. This company

Map of South Africa.

has secured control of the South Columbus and Alta Quincy mines at Alta, and it is the intention to operate upon an extensive scale. — Shareholders of the Silver Bell Mining Co., operating at Park City, have authorized an increase in the capital stock from 250,000 to 750,000 shares; the entire increase, including 25,000 shares of old company stock unissued is to go into the treasury. — Articles of incorporation of the Surprise Mining Co., to operate in American Fork district, have been filed. C. W. Earl, of American Fork, is president. — The Weber County Mining & Milling Co. has been formed at Ogden, with Albert Scrocroft as president.

Samuel Newhouse, operating the Cactus mine in Beaver county, has announced that the capacity of the mill now in commission is to be doubled within the next four months and that eventually it will be doubled again. The plant is now treating 800 tons of ore per day. The improvements are to be made in consequence of the development recently of a tremendously large orebody. Mr. Newhouse says that on the 500-ft. level where the orebody has been cross-cut for 285 ft., it will average between 2 and 2½% copper and on the 600 the assays are even better, the copper having increased from 2 to 4% with more gold and silver also. — At a depth of 235 ft., in the Talisman mine in Beaver county a body of lead-silver ore has been encountered. The property is near the Cedar mine and the ore is identical.

There is unusual activity being displayed now in the Deep Creek mining district west of Salt Lake and it seems certain that at least one railroad will penetrate that

region next year. A local syndicate has formed the Utah & Nevada Railroad Co., which has been projected to run in a direct route to Ely, Nev., from Salt Lake. The Western Pacific can get into Gold Hill, the nearest of the Deep Creek camps, from its main line by building a branch line about 30 miles long. The San Pedro, Los Angeles & Salt Lake is also looking into this territory. The Gold Hill mine, owned by the Western Utah Copper Co., is said to have developed into a big thing and is to be operated upon an extensive scale. F. Augustus Heinze and officials of the Bingham Consolidated Mining & Smelting Co., are in control of this enterprise.

The management of the Ontario mine at Park City has every confidence that the drainage adit will be opened again in the near future. The drill-holes, run from a parallel drift, have apparently tapped the main channel and the water is being drawn off through them. The opening of the adit again will mean resumption of development and ore extraction from the lower levels of several of the big mines again.—The management of the Consolidated Flagstaff has made another payment of \$20,000 to the original owners of the property operated by that company at Alta. —The management of the New Stockton mine, at Stockton, will shortly begin sinking below the 1,000-ft. level. Some extensive bodies of ore were opened on this level recently. An aerial tramway will be built early next year, and the capacity of the mill is to be doubled right away. J. J. Trenam, of Salt Lake, is manager.

The ore shipments from the Tintic mining district last week were 136 carloads, the shipping mines and respective amounts being: Ajax, 4; Centennial Eureka, 42; Beck Tunnel, 5; Bullion Beck, 4; Carisa, 6; Eagle & Blue Bell, 9; Eureka Hill, 7; Gemini, 11; Grand Central, 6; Mammoth, 18; Swansea, 3; Scranton, 3; Dragon, 7; Uncle Sam, 3; Victoria, 4; Yankee Con., 1 carloads.—The management of the Carisa mine, in the Tintic district, reports the development of a large body of good shipping ore on the 300-ft. level. It has been cross-cut for 25 ft. Shipments have been made showing 10% copper, 30 oz. silver, and \$8 in gold.

Good weather has aided progress in the construction of the concentration mills being erected at Garfield by the Utah Copper and Boston Con. mining companies.—October was a record-breaker in the way of ore and bullion settlements in Salt Lake, the totals reaching \$3,567,600, or nearly \$1,000,000 more than the showing made in September.

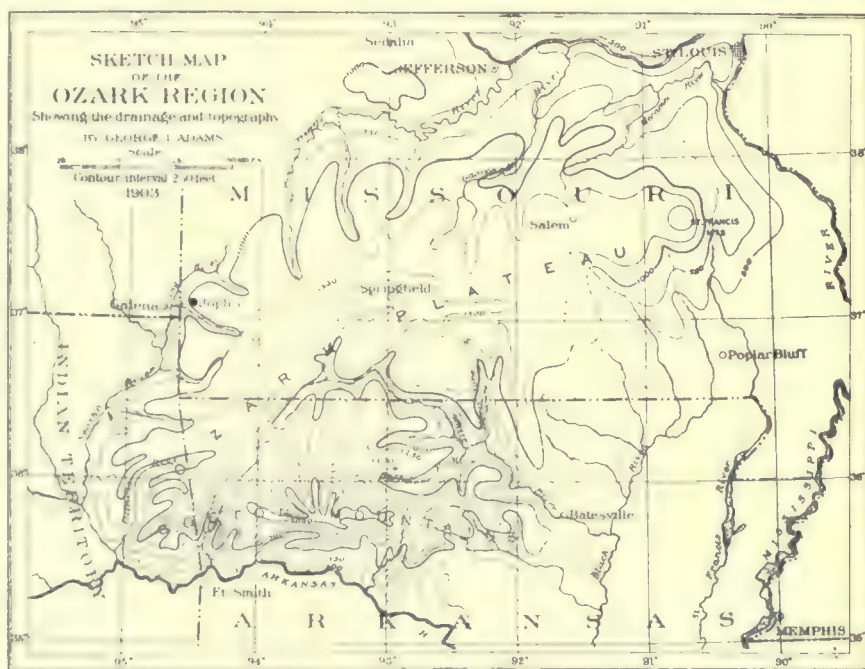

Joplin, Missouri.

High Prices for Lead and Zinc Ore.—Big Output From the Joplin District.—Several New Discoveries.

The highest price reported paid for zinc ore last week was \$48 per ton, on an assay, basis price of \$42 to \$45 per ton of 60% zinc. This is a rise of \$2 per ton over the previous week, both in top price and in the assay basis. The advance was caused by the Mineral Point Zinc Co.'s buyer having instructions to increase his purchases and he was compelled to raise the price in order to get the ore. The highest price reported paid for lead ore was \$83.50 per ton, a decrease of 50c. per ton over the previous week,

but the market continues firm and there is no likelihood of lead going below \$80 for some time to come. The shipment of zinc ore was the second largest of the year, the second week in May this year being the largest in the history of mining in this region; the value was also the second largest in local history. The shipment last week was: Zinc ore, 13,970,630 lb., valued at \$295,884; lead ore, 1,690,740 lb., valued at \$67,540; combined value, \$363,424. Compared with the same week last year the zinc shipment showed an increase of 4,111,280 lb.; and in lead there was an increase of 296,090 lb.; with a combined increase in value of \$92,794. The shipments for the 43 weeks of this year are: Zinc ore, 458,011,300 lb., valued at \$9,887,591; lead ore, 64,526,770 lb., valued at \$2,482,242; combined value, \$12,369,833. This is an increase over last year for the same number of weeks of 41,497,850 lb. zinc and 12,921,260 lb. lead ore and an increase in value of \$1,514,908.

The general outlook in the Joplin mining district was never better, and the year 1906 will go down in history as the greatest on record, but with the great amount of

prospect work now going on and the many new pieces of land being opened up every day, and the many new mills that are being built, the year 1907 will be still larger.

Oscar and E. M. DeGraff, of Joplin, have a lease on 180 acres of the Brooks land, five miles northwest of Joplin, and report that they find it rich in ore. They put down 13 drill-holes and were successful in finding ore in seven of them. Having sunk shafts on two of these holes and encountered a rich body of ore, they have now cut a drift from one shaft to the other and are in splendid shape for carrying on the work. Some large returns will be made from this land in the near future.—The Mercedes Mining Co., of Joplin, has filed articles of association, with a capital stock of 100,000, in \$1 shares, all subscribed and paid in, for a term of 50 years. The stock is held by John R. Holmes, John H. Cape, C. M. Sheldon, all of Joplin, and I. C. Hess of Cartersville. The company has a lease on 16 acres of the Center Creek lease at Webb City, to which place they are moving a mill from one of their Chitwood properties. There has been a large amount of ore taken out of the ground which they have leased, at shallow depth, but they are going to sink for the sheet run of ore now known to exist on the Center Creek lease, and in a short while they will be making a regular weekly output.—Burt W. Lyon, of Joplin, and John W. Durby, of Webb City, who recently began drilling on

their 10-acre lease just east of the famous Lucky Budge mine, on the Aylor land at Prosperity, have succeeded in finding ore at a depth of 167 ft., the drill cutting a body of rich zinc ore and some lead.

Butte, Montana.

October Production.—Important Statistics.—The Snow Storm Mine in the Coeur d'Alene.—Timbering the West Colusa Shaft.—Ore Cut in the Pollock.—Snowhomish and Tramway to Be Worked.—Montana Zinc Co.—Talk of a Merger.—Butte Copper Co. Strikes Good Ore.

The Butte district produced 28,893,240 lb. copper in October. Some of the big producing mines are still closed. The different companies contributed as follows:

Company.	Tons of Ore.	Pounds of Copper.
Boston & Montana.....	93,000	7,161,000
Anaconda.....	105,400	7,694,200
Butte & Boston.....	18,600	1,302,000
Washoe.....	17,050	1,176,450
Parrot.....	11,470	711,140
Trenton.....	16,275	1,139,250
North Butte.....	34,100	4,092,000
Butte Coalition.....	28,675	2,064,600
Original.....	26,350	1,844,500
East Butte.....	6,200	558,000
Pittsburgh & Montana.....	4,340	390,600
Miscellaneous.....	10,850	759,500
Total.....	372,310	28,893,240

The daily output of ore and the average yield per ton in copper were:

Company.	Tons per Day.	Pounds per Ton.
Boston & Montana.....	3,000	77
Anaconda.....	3,400	73
Butte & Boston.....	600	70
Washoe.....	550	69
Parrot.....	370	62
Trenton.....	525	70
North Butte.....	1,100	120
Butte Coalition.....	925	72
Original.....	850	70
East Butte.....	200	90
Pittsburgh & Montana.....	140	90
Miscellaneous.....	350	70
Total.....	12,010	

There is much local interest in the Snow Storm mine in the Coeur d'Alene district of Idaho. Several engineers from Butte, some of them employees of the Amalgamated, have lately visited the mine, and on their own behalf have purchased stock in the enterprise, the shares being worth in the neighborhood of \$3.40. Many inquiries concerning the mine have been received here from financiers in Boston and New York. According to the reports of some of the experts, there is more than 2,000,000, perhaps as much as 5,000,000, tons of first-class copper ore blocked out. This immense body of ore can be extracted, owing to the adits reaching the stopes, at a cost of about \$1 per ton, which is \$2 less than the average cost of extracting ore in the large mines of Butte. The vein has been opened to a depth of 1,500 ft., three adits having been driven into the mountain. The faces of all the drifts are in pay-ore. The vein is 125 ft. wide at the lowest level, and has been opened at that point for about 800 ft. Between adits No. 2 and 3 the vein is 60 ft. wide and assays from 10 to 30% copper. The rest of the mine shows assays averaging about 4%. The richest copper ore carries 7 oz. silver per ton besides the copper. On the lowest level the ore does not run as high in copper, but the experts are inclined to believe that this is largely due to leaching by the water, which flows through the vein matter in great quantities on that level. It is thought probable that the water has carried the copper away and deposited it deeper in the vein as copper glance. In anticipation of this being found true a fourth adit is being driven farther down the mountain, to tap

the vein at a depth of 2,000 ft. W. D. Greenough of Spokane and his associates control this property, as well as the adjoining claims of the Snow Shoe group, which will be opened up in the near future from the workings of the Snow Storm. Last month the Snow Storm Co. distributed \$90,000 in dividends, and the manager is confident that when the concentrating plant is running, the dividends will amount to \$1,000,000 per year.

Re-timbering of the West Colusa shaft has been completed, and the mine is again in operation, sinking being prosecuted with a view to carrying the shaft down to the 2,000-ft. level immediately, or 400 ft. deeper than it is now. With this mine running at full blast, the Coalition will be hoisting in the neighborhood of 5,000 tons of ore per day, which is about 1,500 tons more than the Great Falls smelter can handle. The surplus will be sent to the Washoe, at Anaconda.—The Pollock mine, belonging to the Butte-Milwaukee Co., which is under the control of the Butte & New York Co., has cut the vein at a depth of 250 ft., and has not reached the hanging wall of the vein. The ore runs high in silver.—One of the new companies holding claims east of the Boston & Montana mines on the flat, is the Colusa-Leonard Extension Co., which was organized only this summer, and has already begun sinking a shaft. The promoters hope to strike the productive veins of the Leonard and West Colusa mines where they extend under the flat. A small hoist will serve until the 500-ft. level is reached, when a larger plant will be erected. The four claims held by the company comprise 45 acres.

The Snohomish and Tramway claims, which belong partly to the Butte & Boston and partly to the Butte Coalition, have not been worked for the past four years, owing to the injunction secured at that time by F. A. Heinze. As soon as the shaft is completed, these mines will be worked for the two companies, and the Minnie Healey mine, of the Coalition, will also be worked from the same shaft. This will be a convenience to the Coalition, as the Minnie Healey shaft is a notoriously bad one, being sunk in soft ground, which necessitates constant repairing. The Tramway shaft has reached the 500-ft. level, and is being raised from the 1,000-ft. level, so that this part of the shaft will soon be completed. Sinking and raising will be continued until the shaft reaches the lower levels of the Minnie Healey.—Work will soon be commenced by the new Consolidated Central Butte Copper Mining Co., which owns ground near the South Butte Co., the holding company for the interests of the Great Northern railroad in this city. The company has interests in property east and west of the Ophir mine, of the Butte Central & Boston Co., besides that lying farther to the east.

In connection with the bankruptcy of the Montana Zinc Co., which owned the Alice mill, burnt last summer, there has come to light a transaction that appears on the face of it to implicate F. Augustus Heinze, or his representatives in the State Savings Bank of this city. Robert C. Morris, the receiver appointed for the company, came to Butte last August, and found among the assets of the company a block of 7,500 shares of stock of the Alice Silver & Gold Mining Co., which was deposited in the State Savings Bank as collateral for a note for \$10,000. The stock has a market value of something like \$50,000. Mr. Morris claims that he tendered the face value of the note with interest in August, the note being due last month, and that the officials of the bank refused to produce the stock and cancel the note. He has commenced action looking to the examination of the books of the bank, alleging that the stock is being concealed by the officials, including F. Augustus Heinze, who is not at present in the State.—There is some talk of a merger of

the affairs of the Montana Zinc Co. with the Butte Copper & Zinc Co., which owns the Emma mine in South Butte. It is supposed that the latter company will begin work on that mine in the near future. The Montana Zinc Co. is waiting in the meantime for the settlement of its entangled financial affairs.

The Butte Copper Co. has cut the large vein of the Trifle claim in its shaft at a depth of 378 ft. The vein was cut by a cross-cut at the 300-ft. level, but it is double in width at the point where it has now been cut, and assays about 4% copper with some silver and gold. The vein is said to be the same as that worked by the Gagnon mine.—The Six O'clock shaft, sinking on the group of claims east of the city, belonging to the Butte Exploration Co., has reached the 1,000-ft. level, and the station is being cut, preparatory to cross-cutting north to the vein. If nothing of value is found, sinking will be resumed.

Calumet, Michigan.

Good Progress at the Hancock Con.—Sinking in the Medora.—Explorations on the Empire Tract.—Activity at the Extremity of the Keweenaw Peninsula.—Improvements at the Osceola and the Wolverine—Osceola Pushing Production.

Steady progress is being made in unwatering the old shaft on the property of the Hancock Consolidated Mining Co., adjoining the Quincy mine on the southwest, and the next few days will see the completion of the work. As soon as the workings can be put in shape, drift-stopping will be started, and shipments to a stamp-mill are expected to follow immediately. This policy of early shipments is characteristic of all mines that are controlled by Thomas F. Cole, of Duluth; John D. Ryan, of Butte, and Capt. James Hoatson, of Calumet. It is only a few months since the Hancock Con. was organized by these interests and by the St. Mary's Mineral Land Co., which owns a one-fifth equity. But the old Hancock mine, which forms a small portion of the Hancock Con., was worked many years ago, when it produced 5,000,000 lb. refined copper. Its old shaft is 1,000 ft. deep, and as this will be unwatered in a few days, it can be made a producer of no mean importance. Therefore, because of the present high price of copper, great advantage will accrue to the company.

At a depth of 150 ft. on its Medora mine, in Keweenaw county, the Keweenaw Copper Co., in which the Cole-Hoatson-Ryan interests have a heavy investment, the showing of copper is excellent. Sinking has penetrated exceptionally rich rock for the last 50 ft. and the copper showing is considered the richest on any of the company's properties. Work will progress much more rapidly henceforth, as the steam-power plant has gone into commission. The plant consists of boiler, compressor, and hoisting engine. Previously drilling was done by hand, but henceforth power-drills will be used and sinking will therefore progress much faster. Three drills are used in sinking the shaft. The compressor has a capacity for 10 or 12 drills and it is planned to cut a station at the 200-ft. level and start drifts east and west from the shaft. Hoisting in the Medora shaft has been facilitated by the installation of a two and one-half ton skip. A good-sized stock pile is being accumulated and will be shipped as soon as arrangements are made for the treatment of the ore. All of the improvements are of a substantial character and designed for service throughout the development period.

Diamond-drill exploratory work on the Empire tract of the Keweenaw Copper Co. is progressing rapidly. It is expected that the drill will intercept the Medora vein in a few days. In the event of satisfactory drill cores,

one or two shafts will be started on that property. The Medora vein was uncovered on the Empire property in a trench some time ago, and good copper ore was revealed. The width of the lode at surface is 12 ft. The Empire is nearly two and a half miles east of the Medora shaft, on the same lode, and thus a long stretch of the company's territory is demonstrated to be well mineralized. Reports are current that negotiations are in progress relative to the Clark mine, near the extreme point of the Keweenaw peninsula, but nothing definite is known regarding the deal. Nearly all the Keweenaw county mineral lands of promise, not held by corporations, are quietly being optioned.

Sinking in the Tecumseh's shaft has been suspended at the ninth level and will not be resumed until production is well under way. At each level, drifts have been started. These will now be extended as drift-stopes, which will furnish the rock for shipment to the stamp-mill. The Tecumseh's production will be limited to about 100 tons of ore daily for some time to come.—Preparations for important improvements are under way at the old Osceola branch of the Osceola Consolidated Mining Co.'s property. A new Nordberg compressor and an entirely new boiler-plant will be installed. The foundation for the boiler-house is being laid. The superstructure will be of steel furnished by the Wisconsin Bridge & Iron Co., of Milwaukee, Wis. There will be five boilers of the locomotive fire-box type from the Pratt boiler works, at Detroit, and the Burt boiler works, at Ripley. When this plant is finished, the old boilers will be torn out of the stone building in which they are housed and the structure will be converted to the use of the new compressor. A 75-h.p. electrical equipment will also be installed in this building.—Work on the new Nordberg conical-drum, duplex-hoisting engine at the Wolverine mine is progressing rapidly. The new engine will have a capacity for operating to a depth of 5,000 ft., carrying the shaft to the boundary line of the Wolverine property.

It is uncertain when operations will be resumed at the No. 1 shaft of the Osceola Consolidated Co.'s North Kearsarge mine. This shaft, which was injured recently by fire, is being re-timbered in the damaged portions as rapidly as possible, but the work has not reached the point where the fire originated. In the meantime, the force at No. 3, the other active shaft of the North Kearsarge branch, is working a greatly enlarged force. At the South Kearsarge and old Osceola branches of the Osceola Con., the production is being forced to the limit. There are two active shafts at each of those properties, and the increase in their shipments will tend to offset the loss through the inactivity at No. 1 North Kearsarge.

Plans have been made by the Mohawk Mining Co. for improvements at the No. 4 shaft. A new steel self-supporting smoke-stack will be erected, the contract having been let to the Wisconsin Bridge & Iron Co. A new Green fuel-economizer also will be installed at No. 4. These improvements will complete the heavy construction era for the Mohawk's four northerly shafts and provide the mine with permanent equipment for the remainder of its period of production. No. 5 shaft, the Mohawk's most southerly opening, is provided with a temporary equipment, but it will suffice during the shaft's development period.—Trenching has revealed the outcrop of a lode 20 ft. wide on the Arcadian property. The formation bears some resemblance to the Baltic lode. The cross-cut at the 200-ft. level of the new exploratory shaft was recently resumed, and it will be driven eastward until the formation exposed at surface is cut. The Arcadian has cut a number of cupriferous measures in its new exploratory shaft, but none of them revealed anything of exceptional promise, nor can the prospects be

considered inviting.—Within a short time the Calumet & Hecla will use electrical power for pumping water at its station on Lake Superior, five miles from Calumet. The pumping plant at that point furnishes all the water for domestic purposes at Calumet, Laurium, and Red Jacket. This water system is being extended to its stamp-mills at Lake Linden, where only artesian water for boiler and domestic purposes is now available. This is because the water in Torch lake is polluted by the sand discharged from the mills.

Toronto, Canada.

Prospecting Season Ends in Northern Ontario.—The Colonial Silver Mines.—News From Mines at Cobalt.—Monthly Returns to be Published.—Native Silver in Port Arthur.

The prospecting season in the Cobalt district and northern Ontario generally is now practically over, as snow has fallen in sufficient quantity to put a stop to operations in most localities. At the leading mines most of the shaft openings have been enclosed in preparation for the winter, so that underground work will be pursued uninterruptedly.

The syndicate which recently secured the McLeod and Glendinning property, of which Charles B. Flynn, of New York, is a prominent member, has organized the Colonial Silver Mines, Ltd., and is buying other properties, having already secured 140 acres. Anson D. Cartwright, formerly with La Rose, is superintendent and has a force of 20 men at work. The company has ordered a complete plant, including a 300-h.p. air-compressor from the Rand-Jencks Co., and will increase the force to 200. A vein one foot wide was found last week, the ore of which is stated to run as high as 5,000 oz. silver per ton. It is claimed that in sinking the shaft, 300 ft. distant, a continuation of this vein was struck at a depth of five feet, having at this point a width of four feet of ore with five inches of pure silver in the middle of the vein. Ore from the mine is being sacked for shipment.

The syndicate which has purchased the Green-Meehan mine, two miles north of Cobalt, has appointed as superintendent Charles O'Connell, who has had a long experience in California and Nevada mining. Twenty-five men are now on the payroll and nine veins have been discovered and traced. A complete plant will be installed by Christmas.—The re-organization of the Foster-Cobalt Mining Co. has been completed, with W. K. George as president and W. H. Blake as vice-president. A first-class plant has been shipped to the mines.

The Right of Way mine is proving very productive. One ton of first-class ore has already been extracted, including a quantity of native silver.—The Red Rock mine has been sold to a Toronto syndicate, represented by E. A. Osler. Before the deal was finally put through the owners offered \$30,000 to call it off, but the syndicate refused. A large quantity of ore is awaiting shipment.

La Rose Mining Co. has sold the refuse ore which has been accumulating in large quantities on the dump at \$25 per ton, which will realize about \$250,000. It will be shipped to Providence, R. I., for treatment.—At the Nancy Helen mine the shaft-house and other buildings are completed and about 25 men are steadily at work with two loads of high-grade ore ready for shipment. The company will shortly begin operations on another location in Bucke township.—At the Nipissing mine, the company is installing a mechanical sampler furnished by the Allis-Chalmers Co., by means of which the exact value of ore shipped can be ascertained. It is the first of these machines to be introduced in the Cobalt district.

The Temiskaming & Northern Ontario Railway Commission has recommended to the Government of Ontario the publication of monthly returns of the shipments of ore from Cobalt. It is probable that this system will be

adopted. This will have a tendency to discourage speculation in non-productive mines.

The American Madoc Mining Co., which is working pyrites mines in Hungerford township, Hastings county, and at present employing over 40 men, is preparing to erect large chemical works for the manufacture of sulphuric acid. The staff will be increased to about 150.—At the West End Silver Mountain mine, in the Port Arthur district, now being operated under the management of Capt. Hanson, a vein of almost solid silver was struck on October 27. Samples of the ore, some of them of pure silver, one of which weighs 100 lb. and valued at \$600, have been brought to Port Arthur. The vein was known before, but had been lost. A carload of the ore is being shipped to Omaha. Much of it is so rich that it is not passed through the stamps, but sent direct to the smelters. An adit is to be run from the West End mine to the Shuniah Weachu mine, over 2,000 ft., and it is anticipated that it will strike several veins.—The Three A, once a noted silver-producing mine, on Thunder bay, east of Port Arthur, which has laid idle for about 30 years, has been bought by New York capitalists. The price is given as \$75,000. Operations will shortly be resumed.

Cripple Creek, Colorado.

Production in October.—A Good Showing.—The Midget Doing Well.—The Lucky Corner Strikes Ore.—Discoveries in the Index and in the Acacia. British-American Co. Does Well.—The Ophir Makes a Record.—General Activity Despite Snowstorms.

The October production of the Cripple Creek district shows a gain over that of September. The smelters, reduction plants, and cyanide mills treated approximately 42,800 tons of ore from the camp, valued at \$1,570,300. This is a little over \$100,000 better than September, which is satisfactory, considering that several of the mines are holding their ore in reserve for treatment by the cyanide mills now in course of erection, and that the recent heavy snowstorm impeded mining operations for nearly a week.—The Midget mine on Gold hill is making regular shipments. Operations are being conducted principally on the 900-ft. level, where the best ore is broken. The ore ships about \$30 per ton. Adjoining the Midget is the Moon Anchor, where the Union Leasing Co. is doing exploratory work. The same leasing company has also taken hold of the south half of the Clara D. claim of the Lexington Co. It is proposed to extract the large body of low-grade ore recently encountered in the Lexington mine and which that company has been shipping to the Anaconda cyanide mill. Forty-five tons per day, running \$6 per ton, is being treated.—A two years' lease has been granted to McLeod, Redford & Co. on the World's Fair claim of the Gold Bond Co. on Gold hill. Cross-cuts are being driven at 365 ft., with the object of reaching the World's Fair Pointer shoot, which produced so well in the Accident claim and in the upper levels of the World's Fair, formerly under lease to H. T. Anstie. Royalties range from 15 to 25 per cent.

The Lucky Corner Gold Mining & Tunnel Co., leasing on the middle block of the Little Clara claim of the Work company, has struck ore at a depth of 580 ft. in virgin ground. Operations are carried on through the Moffat tunnel at a distance of 5,000 ft. from the portal. Values and dimensions of the orebody are not to hand, but sylvanite has shown up in many places. The vein is thought to be an extension of that in the adjoining block, where Marsh, Hodges & Co. have one of the richest leases in the district.—Another find of ore has been made in the Index mine on Gold hill. The Aetna Mining & Leasing Co. is at present operating this property, William Foley being manager. The vein was encountered at a depth of 360 ft., and is said to be six feet wide, and as

says have been obtained from it as high as 20 oz. per ton.—The Abe Lincoln mine of the Stratton Estate, in Poverty Gulch, has been shipping some high-grade ore recently. The Tunnel Mining & Leasing Co. is working this property, doing a considerable amount of development. A large quantity of medium-grade ore is on hand, which it is intended to ship to the Golden Cycle mill at Colorado City on the completion of that plant.

Hoisting has commenced on the Morning Glory No. 6, operated by L. G. Henry and associates. A vein two feet wide is being mined at a depth of 250 ft. near the shaft. The first shipment will be made in a few days.—The output of the Henry Adney mine on Beacon hill is averaging 400 tons monthly. The grade is said to be as high as \$80 per ton, one car running nearly \$200 per ton. It is proposed to install new machinery and increase the tonnage. M. B. Burke is owner and general manager.

The W. P. H. Leasing Co. has obtained a lease on the west half of the Teutonic claim of the Teutonic Consolidated Gold Mining Co., lying southwest of the present workings of the W. P. H. claim. Drifts are being advanced toward the side line of the Teutonic, one drift being already up to the line and another 40 ft. from it; both these will cut the Teutonic ground at a depth of a little over 300 ft. It is hoped that several veins that produced well in the upper part of the Teutonic ground, will be encountered at the lower level and be of as good grade. A. B. Whitmore is in charge of the company's interests.—A strike of ore has been reported in the old Burns shaft near the town of Altman, belonging to the Acacia Co. J. B. Neville and partners have this property under lease and obtained the ore at a depth of 360 ft. The vein is 6 in. wide, but said to be remarkably rich, free gold showing in many places. A carload will shortly be shipped.—One of the largest compressors in the district has just been installed by the Golden Cycle Co. at its property on Bull hill. It is an Ingersoll-Rand and has a capacity of 40 drills. A new building has been specially built to accommodate this machinery.—The British-American Mining Co. Ltd., leasing on the South Dante, on Bull hill, has done extremely well during the month of October in spite of the recent bad weather. For several days the road from the mouth of the Trail tunnel to the Eclipse switch on the Midland Terminal railroad was impassable. This company has shipped nine cars of ore during the last eleven days. The bulk ore is running a little over an ounce and the screenings 2½ oz. per ton. The filled-stope method of mining is being adopted, there being at the present time over 300 tons of broken ore in the stopes. Four machines are working on ore.—The October output of the Ophir mine on Raven hill will approximate \$75,000 in value. An average of a car a day has been shipped from this property, every one of which has run better than 4 oz. per ton. This is a good record.

London.

An Onslaught on American Mines.—A Cobalt Flotation.—Queensland's Mineral Production.—Cyanide Practice in New Zealand.

The editor of a financial weekly, generally much occupied with Indian gold mining shares, has turned aside from that engrossing subject to warn the innocent British speculator against American mines. It might be imagined that such of these mines as have the advantage of an English directorate would escape censure, but no; for readers are reminded of the ruinous lawsuits brought against the Richmond Company and the Montana Company, and it is vaguely hinted that the same blow or something equally terrible may at any moment fall on other companies interested in mining property in America. This indiscriminate onslaught recalls the

vivid contrast so beloved of moralists—the naughty boy who absented himself from Sunday school to trespass in his neighbor's orchards with the result that eventually he graduated for the gallows, with honors, while the good boy who attended regularly grew up to be Prime Minister of his country. Perhaps the most heinous offence of all in the editorial mind is that “the companies are registered under American law, and there is no guarantee that shareholders will have those regular reports which English companies are accustomed to issue, or that those meetings will be held at which directors are required to give an account of their stewardship.” The privilege of showing up at public meetings to heckle directors or to make a speech to be reported at length in one's favorite journal is a prerogative highly cherished by certain speculators, the volume of whose ‘investments,’ as a rule, forms a striking contrast to the frequency of their appearance in public.

A propos of big rivers in the vicinity of eligible town sites, and the providential provision of mineral wealth for Britain over the seas, Cobalt may be cited as a remarkable instance, which a new company, the Cobalt Town-site Silver Mining Co., Ltd., is preparing to turn to account. According to numerous press notices now appearing, the Company's property adjoins La Rose, the romantic pioneer of the district, and is even of more pronounced richness than this older mine. It is stated that a Government assay gives the value of its ore at \$4,000 per ton, and there is an immense body of silver ore in sight. Intending investors are informed that the shares in this latter concern, the par value of which is £1, will shortly be introduced to the London market at a price of £2.

Regarding another part of the Empire, Queensland's mineral production in the past year is reported as of the value of £3,726,275, being the highest in the history of that State, and although the yield of gold decreased, the sustained improvement in the production of other minerals more than compensated for it. The high prices prevailing for most minerals other than gold greatly stimulated production. An improvement is also visible in the production of coal, owing largely to the liberal concession made by the Government in foregoing part of the port dues on vessels loading 500 tons or over for bunker purposes. The development likely to take place on the Etheridge, Cloncurry, Mount Morgan, Glassford Creek, Mount Cannindah, and other mining centres points to such increased production that the value of Queensland's output of minerals this year is expected to surpass even that of last year.

From New Zealand some new experience is gained in the milling operations of Waihi Junction, recently started. It would appear that the production of slime is excessive and consequently more filter plant (Moore system) is required. From August 20 to October 6 twenty stamps ran 24 days, and crushed 2,800 tons; average value of ore, £2 7s. 0d. per ton; estimated extraction 80%, equal to £5,300; bullion shipped £2,200; remaining in plates and boxes £3,100. Duty per stamp 5.83 tons per day. It was originally estimated that the stamps would crush about four tons per day, and the necessary plant for treating the resulting slime was provided on this basis, under the best expert advice. It has been found that not only is the efficiency of the stamps greater by nearly 50%, but a far larger proportion of the ore is reduced to slime than was anticipated. In consequence of this increased production of slime, milling operations have been interrupted and curtailed. When it became apparent that the filter-presses were inadequate to deal with the large quantity of slime formed, steps were immediately taken to provide the additional plant required.

Mining Summary.

ALASKA.

A discovery of gold has lately been made on North river, a tributary of the Unalakleet. While good prospects have been found on the river and its smaller tributaries no defined body of pay has yet been found. No work has been done to speak of other than sinking a few shallow holes, none of which has yet been put to bedrock. This is a well mineralized section and may develop into another large producing district.—The grading crew on the Wild Goose Co.'s pipe-line from Pilgrim river to Nome have been laid off, but the pipe-laying crew are rushing operations as rapidly as the conditions will permit. It is the intention of the company to lay all the pipe that is at present on the ground before the close of navigation. During the coming winter several miles of pipe will be hauled to different points along the line, and will be connected next spring. The line when completed will have a capacity of about 4,000 miners' inches.

ARIZONA.

GILA COUNTY.

(Special Correspondence).—The Live Oak Copper Co., at Globe, is working a considerable force sinking an incline-shaft and preparing for the installation of a hoist and air-compressor. The shaft is down over 100 ft. and is bottomed in 9% ore. The mine has one of the largest bodies of silicious copper ore of good grade in the district; it produced \$100,000 when worked by Boom & Strang, lessees, and was lost by the caving in of the workings. The new shaft is being sunk for the purpose of re-opening this orebody and to re-establish the Live Oak as a productive mine.—The Globe Consolidated is working a large force of men at the Gem shaft; the number will be increased as rapidly as conditions will permit. The shaft is down 88 ft. and the first set of timbers is being put in. After the work at the shaft is well under way it is expected that the company will gradually expand operations.—Water has been struck at 558 ft. in the Black Hawk shaft, and the flow has increased until work had to be suspended. A pump will be installed soon, when the management expects to be able to sink 800 ft. and open another level. Aside from the suspension of work in the Black Hawk shaft, caused by an unexpected volume of water, the Arizona Commercial Co. has made good progress of late. The cross-cut at the eighth level has now been driven 300 ft. and is in an altered line, which is considered a favorable formation for the occurrence of ore. The grade for the standard-gauge railroad which is to connect the company's mines with the Old Dominion smelter is completed. Several cars of bridge timbers are being unloaded where needed.—The Keystone Copper Co. is shipping 20 tons of 12 to 15% ore per day to the Old Dominion smelter, and expects soon to increase shipments to 75 or 100 tons daily. It is working a force of 50 men. The mine is looking well and the stopes showing steady improvement.—The Inspiration Mining Co. is busy moving machinery and grading for its concentrating mill, and progress is good.

Phoenix, November 5.

PINAL COUNTY.

It is reported that the Lake Superior & Arizona Copper Co. will construct a railroad from Florence to Superior, and erect on the river near the Florence depot a 250-ton smelting plant. Mr. Sieboth, the general manager, will so plan the initial plant that its capacity can be doubled by a simple addition of furnaces, and as the company will treat custom ore with its own ore, it will not be long till a doubling of the furnace capacity will be necessary. The Superior mine alone is capable, with its present development, of keeping a 250-ton plant busy, and two years hence a 500-ton plant will hardly meet its requirements. Surrounding Superior and all along the proposed railroad down to within 12 miles of Florence are numerous mines, capable of large production, and the moment the railroad shall have been completed and the reduction plant placed in operation, ore shipments will commence from all these mines, and the same will be true of the mines along the Gila river from Florence to Christ-

mas, including the Butte, Kelvin, Riverside, Ray, Mineral Creek, Troy, Ripsey, Banner, Bunker Hill, and Mammoth districts. The most distant of these districts is only 25 miles from the proposed smelter site at Florence, and are reached by the Phoenix & Eastern railroad.

CALIFORNIA

INYO COUNTY.

The Iron Mask group of 16 copper claims, situated 17 miles southeast of Greenwater, has been sold to the Pittsburgh & Greenwater Copper Co. for \$200,000. Mr. McGarry is general manager.

SAN BERNARDINO COUNTY.

Another discovery of large copper deposits is reported in the Silver Lake region, 50 miles from Ludlow. A number of prospectors are heading for this district and also to Coma, where a find of native silver deposits is reported.

Contractors on the Tonopah & Tidewater railroad are experiencing great difficulty with their employees in the Amargosa cañon. The excitement over copper discoveries is so great that the laborers are leaving in large parties to indulge in the luxuries of a rush to the new camps.

SAN DIEGO COUNTY.

Kuntzite has been found at Pala. The discovery was made in a copper prospect, and about 15 lb. of this gem stone was taken from a pocket. Kuntzite is a beautiful variety of spodumene of considerable value.

SHASTA COUNTY.

Developments in the Mammoth mine are proving the orebody to be of enormous extent, and the life of the mine is proved to be more than ten years, and it is more than probable that the exploration now under way will double or treble this estimate. Diamond-drills are proving new ground and valuable discoveries have been made. The company has also acquired valuable holdings, with large croppings in the neighborhood of the Mammoth mine. Engineers are also scouring the northern part of the State to find new deposits. At the smelter new bins have been completed to increase the storage capacity for sulphide ores, as the aerial tramway has caused so much trouble by accident and delays that the smelter has been in serious danger of a partial shut-down on several occasions. It has been decided to add two blast-furnaces, two converter stands, and an electric crane to the present equipment. The new furnaces will be 180 by 50 in. at the tuyeres, each having a normal capacity of 400 tons per day.—A very high capacity, about 25% above normal, has been maintained at Kennett lately. Under the management of H. S. Haskell, who did so much in the development of pyritic smelting at Keswick, the percentage of coke has been greatly reduced, and the capacity of the furnaces increased as a natural result.—At the Balakalala mine development is proceeding, especially at Windy camp, which is about a mile north of the Balakalala, but no quantity of ore will be extracted until the tramway to Coram is completed.

TRINITY COUNTY.

The La Grange Co. has bonded numerous properties on New river and will work on a still larger scale.—The Noble and McAfee properties have been purchased by Dr. Williams.—At the Bear Tooth mine a mill is in operation, and hydraulic mining will also be commenced on an adjacent property.

COLORADO.

MINERAL COUNTY.

George D. Nickle of Del Norte who has been receiver for the Ridge mine for the past eleven years, has sold it to Pittsburgh parties who will start work on a large scale. It is understood that Mr. Nickle was able to pay about 90c. on the dollar.

PARK COUNTY.

John Kuhn, manager of the London mine, is sinking a winze 150 ft. on the vein. If the ore continues in this winze arrangements will be made to drive a lower adit which will tap the vein something like 700 ft. below the present level. It is estimated that the adit will be 4,500 ft. long and will require two years to complete. There is also some talk of an electric road being built from the London mine to connect

with the C. & S. railroad at Alma. There is already a spur for some distance up the gulch, but is not in service at present.

SUMMIT COUNTY.

(Special Correspondence).—The Victoria mine has been taken over from the Masontown Mining & Milling Co. by G. D. Hibbs, who intends to develop the property and work the large sulphide orebodies. The main shaft will be sunk to the depth of 200 ft., and a hoist and pump installed. A tunnel will be driven at the bottom of the Mt. Royal, about 800 ft. long, and will cut the lode at sufficient depth to give nearly 1,000 ft. of stoping ground. In all probability the mill on the property will soon be put in action again.—About a mile and a half west of the Square Deal property, in the north Ten Mile cañon, a good gold vein has been discovered by two local miners, who have taken up a group of claims and formed a local syndicate to open up their discovery. Samples from the outcrop gave returns of \$6, \$8, and \$10 per ton, and after the location work had been done, a 12-ft. vein gave an assay of \$12 for the entire width. The nature of the ore is different from anything else surrounding it and appears to be the making of a free-milling gold proposition.—An important strike has been made on the Kitty Innes by the lessee, George Berry. In driving the lowest tunnel into Peak 1, a vein was discovered which carries 4 ft. of solid ore, the majority of which is chalcopryrite of a good grade, which will return from \$80 to \$90 per ton.—The lessees on the Juno are doing well and making regular shipments of a good grade of ore.

Breckenridge, Nov. 3.

IDAHO.

CUSTER COUNTY.

The smelter of the Lost Packer mine, at Ivers, Idaho, which was put out of commission by an accident only a few hours after being started, will not be started again until spring, owing to the deep snows making winter work impracticable.

NEVADA.

ESMERALDA COUNTY.

The Florence Leasing & Mining Co., operating the Lindsey lease on the Florence next to the famous Reilly lease, has opened up ore in several places on the lease. At present only one stope, on a six-foot vein giving high assays, is being worked owing to inadequate hoisting facilities. The new hoisting plant has arrived, however, and is now being installed. The shaft, which is now down 275 ft., will immediately be lowered another hundred feet.

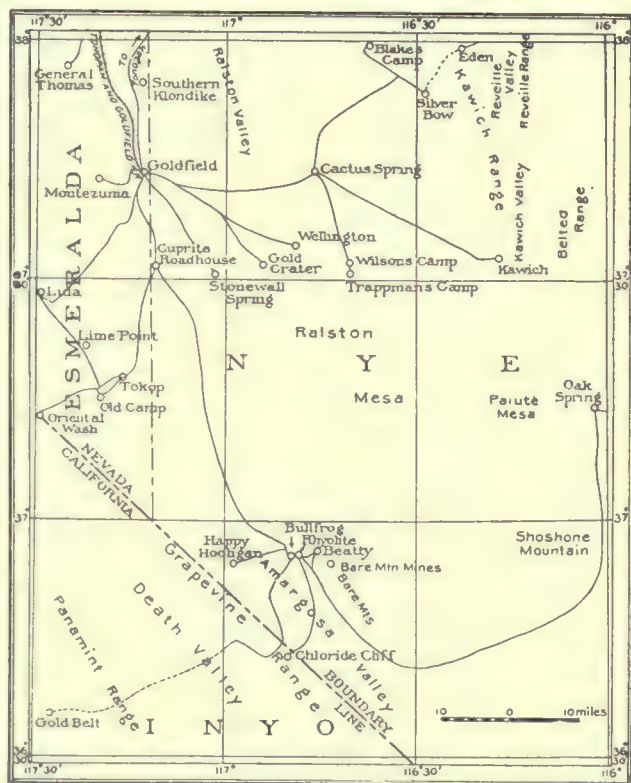

HUMBOLDT COUNTY.

Lessees at the new discovered Cleghorn lode, at Seven Troughs, are finding good shipping ores at slight depths. Water is being piped from a strong spring 2,000 ft. above the new strike. The workings are at present less than 50 ft. deep.

LINCOLN COUNTY.

(Special Correspondence).—The railroad grading camp has been moved to within four miles of Searchlight and the work is progressing with more speed than heretofore owing to the cool weather and the fact that the contractors are able to secure more labor. The Manville stage running along this line will soon be discontinued as local bus lines can handle the passenger and express business at less cost and more convenience to the public. Lots have been platted and a site selected for the station house on the Boulder group of claims adjoining the Cyrus Noble property.—Henry B. Adsit, manager of the Colorado Mining & Milling Co., is down 240 ft. in his double-compartment shaft.—At Camp Thurman near Newberry mountain a townsite is being formed by B. S. Nagle of Butte, Montana. He has located eight claims and reports that he has shipped two sacks of ore to Los Angeles as samples, which show exceptionally high values.—Ernest G. Locke, a mining engineer from Seattle has bought the Golden Rod group of claims lying 1 1/2 miles from Searchlight for \$10,000. There is a remarkably good showing on assays taken from samples on this property. The vein croppings extend the entire length of the three claims. Several shafts have been commenced, the deepest being about 50 ft. A contract has been let for 200 ft. more work which will commence at once.—The Newberry

Mountain district proper is attracting wide attention. Many prospectors, mining engineers, and curiosity seekers take in this territory when visiting Searchlight and a large number of claims have been located. Reports are very favorable and numerous outfits have been made up here bound for that district.—The owners of the Gold Dyke have arranged with contractors for the continuation of their 103-ft. shaft. Considering the small amount of development work done on this property, the showings are remarkably good and it is generally considered that the mine has a great future.—Artesian wells are to be sunk in Searchlight for irrigation purposes. The soil here is exceedingly fertile and where experiments have been made with irrigating such as was done on a large garden plot on the Pompeii property, the best possible results have been obtained. The so-called desert is doomed as far as this particular locality is concerned. Work on these wells will be commenced immediately with competent engineers in charge.—A good show-

Part of Nevada.

ing has been made on the Sunday Morning group of claims a mile north of the original strike at Trull springs. This property is owned by E. P. Trull, L. M. Stepp, and A. B. Brock. They will commence development work in the course of ten days.

Searchlight, Nov. 2.

LYON COUNTY.

The Nevada Douglas mine, at Yerington, has reached sulphide ore in the bottom of its double shaft, assaying 21.5% copper. This shaft has been in a carbonate ore all the way down.—The Sunlight shaft, in another part of the property, is also coming into sulphide ore.—The Blue Jay is not shipping now, but has been a heavy shipper. The property adjoining it on the south is that of the Yerington Co.; that next south of this is the Copper Mountain.—The Mason Valley, in its upper working, has driven a shaft 105 ft. deep and at a distance of 75 ft. on the incline shaft it cross-cut the orebody, 115 ft. in width, the shaft being all in ore averaging about 5% of copper sulphides. It started a tunnel lower down at the base of the hill and expected to drive in 600 ft. before reaching the orebody, but at 450 ft. ore was encountered in the foot-wall, through which they have 50 ft. with no indications of its giving out. This ore averages about 3% copper.

NYE COUNTY.

(Special Correspondence).—Mining development in and around the town of Central, two miles west of Manhattan, is rapidly bringing that district to the front. More miners

are employed on the property of the Manhattan Nevada Gold Mines Co., owning the Georgey and El Dorado groups, than on any other one property in the district. The adit on the Georgey group is in the hill 250 ft. and three large veins have already been tapped, while on the surface, others have been opened by shafts and cuts, all of which will be cut by the adit in the near future. Vein No. 3 is 22 ft. wide, and strong, crossing the formation at right angles, and will intersect all other veins in the hill. This large vein could all be run through a mill at a profit.—The Manhattan Giant, to the north and adjoining the Georgey group, have erected a hoist which is now in operation, hoisting high-grade milling ore from a strong four-foot vein. Six men are employed on this property.—The Original Manhattan Mines Co., between the Giant and El Dorado, have gold, silver, and lead ores in large quantities. A hoist is on the ground and will soon be erected and in operation. Several tons of high-grade ore have already been shipped from this property, netting the company a handsome profit.—The Manhattan Nemo Mining Co., to the west and adjoining the Georgey group, have large quantities of lead and silver ore in one of their veins, and a high-grade streak of gold ore in another. Extensive development work is being carried on.—The Independence, Houligan, and Paymaster properties, a mile northwest of Central, are all working in high-grade milling ore, and several sacks of high-grade ore are to be found on the dumps, awaiting shipment.—In Manhattan, the sensation of the week is the strike made at the 200-ft. level on the Manhattan Con., where rich ore is being taken out and sacked.—The adit on the Manhattan Mother Lode Mining Co., is being pushed forward rapidly, now being in the hill 175 ft. Five veins have been crossed, all carrying good milling values, and driving will soon be started to block out these orebodies. Leads have been opened on the surface, carrying high values, and the tunnel is being driven ahead to encounter these veins at depth.—The cross-cut from the 90-ft. level in the shaft of the Manhattan Cowboy Mining Co. is in 125 ft., and the dolomite, through which they have been driving, is now being left behind, and good vein matter coming in.—The shaft on the Manhattan Express Mining Co. is progressing rapidly, and the lava flow which covers the surface has been pierced, disclosing a most favorable formation. Cross-cutting will be started a few feet deeper, to discover various veins carrying values that have been traced into the Express Co.'s holdings.

Manhattan, Nov. 4.

WASHOE COUNTY.

Development work on the Rocky Hill group of claims, situate 15 miles south of Reno, on the V. & T. railroad, is proving a series of parallel veins carrying about \$16 in gold.

WHITE PINE COUNTY.

At the Success mine, where a big strike was recently made, a great deal of work is now being done. Two 150-ft. shafts have been sunk upon the property, and at that depth air connections have been made between the shafts. A continuous orebody has been found to a depth of 175 ft., which is as far as development work has gone. The ore vein is from 8 to 25 ft. in width, and the ore is rich in lead, silver, and gold. Two 85-h.p. boilers have been set up on the Success property, and a compressor plant is being installed. A sawmill, to be used in cutting timber for the mine, is also being put in. Abundant water is being procured from a spring above the property, 4,000 ft. of pipe having been laid to carry the water from the spring to where it is needed.—The Duck Creek lead belt extends about 15 miles to the north of the Success mine, and in that area a number of new strikes have been reported during the past few days. At the Ely-Homestake No. 1 mine a vein 20 ft. wide of heavy galena was encountered at a depth of 20 ft. The mine promises to be a good producer of shipping ore.—A shaft 40 ft. deep has been sunk upon the property of El Gibraltar, and a splendid mineral showing has been made by the development work. All of the big Duck Creek mines are now ready to ship ore, and that district will be a busy one during the winter.—At the Cumberland-Ely the rich ore recently discovered in the Veteran workings is improving in quality and shows no signs of decreasing.

OREGON.

BAKER COUNTY.

At the Cornucopia mine 100 men are employed on this property and a 20-stamp mill runs continuously. Pierre Humbert is the consulting engineer and Valentine G. Laubenheimer general manager. The company has completed surveys for a railway from the mine to Hathaway, to connect, at present with freight teams from Baker City and, ultimately, with a line of road from Baker City to Snake river. At this mine driving is in progress on three veins, one of which is 16 ft. between walls, and is all milling ore. The development work pays for itself without stoping and yields an income, besides, to an amount estimated at \$50,000 per month.—The Queen of the West Mines Co. is at work on a property adjacent to the one owned by Mr. Searles. Development work has been going forward on this property for three years but it is only recently that its equipment was completed. The company built a road from the town of Cornucopia to its millsite, a distance of three miles. Its water-power development consists of a ditch 700 ft. long, 2,280 ft. of flume, and 1,300 ft. of 9-in. pipe. The water has a head of 455 ft. Three separate water-wheels are employed in furnishing power direct—one for the batteries and rock-breaker, one for the vanners, and one for the generator, which furnishes power and light for the drills and the mine. The ore is conveyed to the mill by a tramway 3,140 ft. in length and there is an additional tramway 560 ft. long, connecting two of the tunnels. Ore sufficient is blocked out to run the mill 18 months. The average width of the vein is $4\frac{1}{2}$ ft. and the average milling value of the ore is \$22 per ton; 46 men are employed.—The Mayflower also situated in this district, is owned by the Stampede Mining & Milling Co. A 10-stamp mill and an 80-ton per day cyanide plant have been recently installed; 35 men are at work on this property.

UTAH.

JUAB COUNTY.

The shaft of the American property near the Beck tunnel is now down nearly 150 ft., and but little more development work will be required to open up the ore deposits which extend from the Beck tunnel into this ground.—A small force of men is now at work at the May Day taking out some of the old plant, and this will be replaced with improved machinery which will enable them to handle the May Day successfully. It is thought that these changes can be made within three or four weeks, and then trial-runs upon the different grades of ore will be made.—The foundation for the new machinery of the Little Chief Co. was completed last week, and the boiler has been put in position. The gallows-frame is now being put up and Joseph Hannifin, the superintendent, expects to have everything in shape so that work can again be taken up in the mine within a week.

SALT LAKE COUNTY.

A 50-ton shipment has been made from the Carisa mine valued at about \$70 per ton. H. S. Joseph, the general manager, reports that a cross-cut on the 300-ft. level has been in ore for 25 ft. and that the other wall is not yet in sight.

BRITISH COLUMBIA.

At the Last Chance mine, which is owned by the Last Chance Mining Co., of Spokane, a strike was made last week. The tunnel in which the new strike was made is a continuation of a tunnel of the American Boy which had been driven to the line of the Last Chance claim, and which was purchased by the latter company. Men have been working in the drift since the company resumed operations a few months ago, and a good body of ore has been found. There is now 10 in. of high-grade galena ore, and the face of the drift is spotted with mineral. At the point where the orebody was encountered they have a vertical depth of 1,000 ft., and they can drive 1,000 ft. more before reaching the end of their ground.—Development work has been discontinued at the Meadow Lark claim. When the gallows-frame is completed for the Granby's new Victoria shaft it will be over 100 ft. high.—Since the visit of M. M. Johnson to the Maple Leaf group, Franklin camp, recently

bonded by the Dominion Copper Co. for \$125,000, preparations have been made at the property to house the working force for the winter. — This week several hundred tons of ore were sent out from the B. C. mine, Summit camp, to the B. C. Copper Co.'s smelter, the first shipment in a couple of years from this old-time shipper. The Oro Denoro will re-join the shipping list soon. — Eastern coke is now arriving at the Granby smelter.

Both in Rossland itself and in the vicinity a distinct revival of mining has taken place owing to the new discoveries of richer ore in the deeper parts of the principal mines, discoveries which R. W. Brock, acting for the Geological Survey, had predicted. The work of Mr. Brock and his assistants is much appreciated in the district, owing to the renewed confidence it has imparted both to mine managers and prospectors. At Trail, alterations and additions are being made to the smelter, and similar improvements are taking place at Nelson, Grand Forks, and Greenwood, showing that the output of the mines supplying these furnaces is such as demands more extensive and better plants for its treatment. All the mines of the Boundary copper camps are active, and their general tone appear to suggest healthy improvement.

At the silver-lead districts of Slocan there is an awakening also; several mines are working profitably. The find-

Map of Part of British Columbia.

ing of the vein of the Rambler-Cariboo mine at a depth of more than 1,200 ft. is of the greatest importance to the district, pointing as it does to the probability of the silver and lead ores being found in depth. — At Hedley, in the Similkameen valley, the large Nickel Plate mine gives surface indications of large orebodies, and when the railway freights are reduced, it is expected that these ores will prove payable. C. Camsell, who is working along the Similkameen valley above Princeton, is quite enthusiastic about the large masses of ore in that region which, although low grade, can, he confidently believes, be profitably worked, upon the completion of the railway. On the Coast, about and to the northward of Vancouver, favorable reports concerning the mineral deposits both of the mainland and Texada island are being made, and evidences of progressiveness are everywhere visible.

The strike at Fernie has cut off the coal supplies of the smelters at Nelson and Trail, so that the smelters have been forced to decline further shipments for the present. The same cause has contributed the delay in blowing in at Northport. This makes an embarrassing situation for the many shippers, who depend upon these works for the marketing of their product. Notwithstanding this, however,

the general feeling is that the inconvenience would be a small price to pay for a victory in favor of the open shop at the coal mines. The whole trouble was precipitated by the Union trying to force the company to discharge the non-union men, amounting to less than three per cent of the force, and in view of the arrogance of such organizations of late in the district, the general feeling—shared by probably a majority of the men themselves—is of hope that the company will carry their point and continue to run 'open shop'.

MEXICO.

CHIHUAHUA.

The San Toy Mining Co., in the Santa Eulalia district, is to have a $4\frac{1}{2}$ -mile aerial tramway, which is being built by the Trenton Iron Works. — The Rio de Plata Co. is to have a complete reduction plant, including 25 stamps, a tube-mill, concentrator, a 60-ton cyanide plant, and Robins belt-conveyor. The mine is 110 km. from Aguatos on the Orient railroad. D. W. Shanks is general manager. — The Terrazas smelter, 25 miles from Chihuahua, has started operations on the copper ore of the Rio Tinto mine. Its capacity is 250 tons per day. David Goodale is in charge. — The Batopilas Mining Co. is building a trail from Batopilas to the Orient railroad; this will lessen travel to the railroad from six days to three. — The Monterde Mining Co. is pushing development work; during the year 1,400 ft. of such work has been done under the direction of R. M. Bagg, the general manager. — The Monterde mines are now showing a large amount of ore, the main vein having been cut at 106 ft. below the original workings. On this vein the north drift has been run 160 ft. and has been in ore all the way with four feet in the breast. In doing this work some bunches of very high-grade ore have been cut; 35 men are employed. It will require \$50,000 to build a mill and provide working capital, but when this is done, the mine should earn dividends regularly. — There is talk at Parral of re-starting the Santa Rosalia smelter. — The Refugio mine at Minas Nuevas is spending a good deal of money in improvements. W. J. Morrill is in charge. — The Tres Amigos Mining Co., B. L. Croff general manager, is developing its property by an adit on a vein ranging in width from 25 to 40 ft. The ore is being stacked pending the completion of the railroad from Temosachic; it averages 6% copper, $\frac{1}{2}$ oz. gold, and 4 oz. silver per ton. — The Guaynopa Mining Co., of which Howard Veidel is superintendent, is sinking a winze in the tunnel on the old Guaynopa mine. The winze is down about 40 ft., with a pay-streak two feet wide. It is claimed that some of this ore runs 2,000 oz. silver per ton and the company has already shipped 1,200 oz. ore. — The Utah Mining Co. has a tunnel in over 100 ft. with cross-cuts. The ore is 80 ft. wide and is considered the same body as that in the Tres Amigos.

DURANGO.

The Boca del Cobre mines are reported sold for \$300,000 gold to a company of California capitalists. The deal was made through Thompson & Gilliam, of Los Angeles. The property is in the Nazas district.

Through an option obtained by F. W. Foster, of Mexico City, the Garibaldi mine, of Guanacevi, Durango, which was the property of Arturo Longega, has been purchased by the Mines Finance Co. John B. Farish is its consulting engineer, and is represented in Mexico by George J. McCarty. This was a strictly cash operation, the consideration being considerably over half a million dollars. This mine is on the rhyolite-andesite contact, and adjoins the Santa Cruz mine of the Restauradora group, which was purchased some months ago by the Cia. Minera, Ltd., from the National, Hipotecario, and London banks.

JALISCO.

The Verdiana mine, in the Ameca district, has been bonded to El Vasto Mining Co., of Oakland, Cal. Two neighboring mines—the Atrenda and the Aguila—are doing well. — C. P. Dickinson and J. H. Means, in behalf of the Mexican & General Mines Syndicate, of London, have completed an examination of the San Pedro Analco Mining Co.'s property in the Hostotipaquillo district. These mines have been productive for many years.

Personal.

C. S. HERZIG is in Siberia.

ROBERT T. HILL has been to Cananea.

JOHN WELLINGTON FINCH is at Goldfield, Nevada.

WALDEMAR LINDGREN has returned to Washington.

FORBES RICKARD is examining mines in Nova Scotia.

E. A. H. TAYS is examining mines in Gila county, Arizona.

JAS. W. NEILL can be reached at 159 Pierpont St., Salt Lake City.

R. A. F. PENROSE has returned from South Africa and is at Denver.

EDWARD L. DUFOURCQ is examining mines in Chihuahua, Mexico.

WILBUR E. SANDERS has returned to Helena, Mont., from Alaska.

W. L. LELAND, on his return from Nome, Alaska, has gone to Boston.

GEORGE KISLINGBURY is examining mines in Arizona and New Mexico.

ARTHUR L. PEARSE was in San Francisco and is now on his way to England.

W. F. CROSBY, manager of the Butters plant at Virginia City, is at New York.

C. W. MCARTHUR has returned to Silverton from a short visit to Denver, Colorado.

MARK R. LAMB was in San Francisco for a few days and is now at Goldfield, Nevada.

FRANK H. PROBERT, of Los Angeles, is on a visit to clients at Boston and New York.

T. H. OXNAM has returned to Los Angeles, after a beneficial rest in Cornwall, England.

F. W. BRADLEY and ALBERT BURCH have offices now at 1611 Franklin St., San Francisco.

W. H. NUTTING has been appointed smelter superintendent for the Utah Copper Company.

A. L. HARBISON has returned to Vincennes, Ind., from Denver and Park county, Colorado.

A. C. BLACKWELL, managing director of a dredging company at Burma, is visiting California.

W. E. THORNE is at San Jose, Cal. He expects to take a special course at Stanford University.

L. U. GRATAN is finishing this season's geological work in Shasta county. He is now at Kennett.

CARL HAND is expected shortly in British Columbia to look after his interests on Kootenay lake.

A. P. ROGERS, formerly at San Francisco, has opened an office at 446 Bradbury Bdg., Los Angeles.

JAMES PASCOE is superintendent for the Mount Boppy gold mine, near Cobar, New South Wales.

DAVID W. SHANKS is general manager for the Cia. Minera de Rio de Plata in Chihuahua, Mexico.

H. V. WHEELER, of Los Angeles, is engaged in professional work in the Ballarat district, California.

ANSON D. CARTWRIGHT is now superintendent for the Colonial Silver Mines, Ltd., at Cobalt, Ontario.

W. S. KEITH, assistant superintendent of the Kennett smelter, has resigned and is leaving for Mexico.

CHARLES O'CONNELL has been appointed superintendent of the Green-Meehan mine, near Cobalt, Ontario.

FRANK L. HESS, of the U. S. Geological Survey, is investigating the occurrence of rare metals in Colorado.

W. E. THORNE has been making examinations of placer ground in Park county, Colo., for Eastern clients.

EDWARD W. RALPH is now superintendent underground for the Boston-Ely Development Co., at Ely, Nevada.

A. H. HOLMES is superintending work at the Tres Amigos mine in the Guaynopa district of Chihuahua, Mexico.

E. P. JENNINGS has returned to Salt Lake from three months' work in the iron mines of Michigan.

HILLS & WILLIS, of Cripple Creek, Colo., have opened offices at 318 McPhee Bdg., Denver. They will continue to keep their offices at Cripple Creek.

EDGAR E. BARKER, of Grass Valley, recently with the Progreso Mines Co. in Lower California, Mexico, is now engineer for the Globe Con. Copper Co. at Globe, Arizona.

F. H. NETTLETON, who has been in Alaska during the summer, in the interest of Finch & Campbell, of Spokane, has returned and is now making an examination at Ainsworth, on Kootenay lake.

CHESTER NARAMORE has been appointed Statistician of the U. S. Geological Survey for Colorado, New Mexico, South Dakota, and Wyoming under the direction of WALDEMAR LINDGREN, with headquarters at 612 Commonwealth Bdg., Denver.

Obituary.

JOHN BRECKENRIDGE, general manager of the Paloma Mining Co., of Guadalajara, Mexico, died at St. Louis, Mo., on October 15.

COPPER STATISTICS.—According to James Lewis & Sons, of Liverpool, the imports of copper into Liverpool and South Wales were 68,098 tons fine during the first nine months of the current year, as compared to 61,900 tons during the same period of 1905. These figures do not include Chile copper, of which 13,031 tons were imported, as against 17,316 tons in 1905. The total visible supply is placed at 12,483 tons, as against 16,304 tons this time last year.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

DEPUTY UNITED STATES MINERAL SURVEYORS are exempt from jury duty in the State of California.

ARGOL is a crude potassium tartrate often used by assayers as a reducing agent. The carbon obtained is in the nascent state, and hence is very active.

TUNNELING in stiff blue clay can be assisted by driving spiling forward around the face. This will loosen up the clay and assist the pick and shovel work. A hydraulic jack will be found very useful to drive the spiling used in this system of forepoling.

THE most important regions of thermal activity coincide with the principal centres of volcanic eruption, as illustrated by the conditions in the Yellowstone Park, the Eifel mountains, northern Bohemia, the north island of New Zealand, and the Auvergne.

THE carbon dioxide in thermal springs may be generated from limestone by the action of sulphuric acid derived from oxidizing pyrite, by heat alone if the gas is given an opportunity to escape, or by the reactions of hot solutions of silica during contact metamorphism.

AS MINING in itself is merely the extraction of ore from the earth, and has to be followed by extraction of metal from the ore, the working costs of any given mining business, except for comparative purposes, must cover all expenses up to marketing the final product.

WARMING PANS in which dynamite is thawed should be cleaned at least once a week with warm soda solution to remove any nitroglycerine that may ooze out of the powder. The solution should be made up of two parts of caustic soda and two parts of glycerine to 96 parts of water.

IN Colorado the cost of erecting a mill per ton of ore treated is as follows:

20 to 30 tons capacity daily,	\$250 to \$280	per ton of crude ore treated.
40 to 50 " " "	\$200 to \$250	" " " " "
75 to 100 " " "	\$160 to \$180	" " " " "
150 to 200 " " "	\$133 to \$150	" " " " "

STRONG TRESTLES can be made of 2 by 8 in. lumber, which will serve every purpose on tram-lines for transportation of ore, in cars holding up to two tons and even more. Ordinarily the amount of timber put into structures of this description is much larger than is really required. Such trestles may be safely carried to a height of 40 or 50 feet.

THE earliest phase of volcanic exhalations is distinguished by the presence of fluorine, arsenic, phosphorus, boron, tin, bismuth, copper, iron, and manganese. In the second phase there appear hydrogen sulphide, sulphur dioxide, with other sulphides and bases. The third phase is marked by the presence of carbon dioxide.

NOT only is the practical valuation of a mine dependent usually more on prospective value than on the estimated value of the ore blocked out, but it must be understood that the calculation of this last is by no means a scientific certainty, and that the correctness of the estimate depends on conditions of occurrence which vary in different mines.

IN the construction of assay-furnaces for use with coke, the firebars should be designed so as to be easily replaceable without drawing the fire, the iron bars being

about one inch square and not crowded. The ash-pit should be made with a forward slope, especially if bullion is to be melted. With a well-clinkered furnace, a temperature of 1,400° F. should be easily maintained.

THE Australian miners call the shift from 12 P. M. to 8 A. M. the 'dog watch.' In our Western mines it is called the 'grave-yard shift.' It is the least desirable, as trespassing most severely on the natural hours of sleep. In many mines the breaking of ore ceases during this shift, in order to permit of removing waste and freshening the air in the workings.

A SIMPLE METHOD of handling a copper carbonate ore is that in use at the Snowstorm Co.'s mill at Larson, Idaho, where about 97% extraction of copper is being obtained. After crushing, the ore is run into agitators, where it is mixed with a 10% solution of sulphuric acid and a solution of chloride of lime. Thus a solution of copper sulphate is formed, while the silver remains as a precipitate of chloride. From these agitators, which are three in number, the copper sulphate solution goes through a series of six settling vats. From the solution the copper is precipitated with scrap iron, and the residues containing the silver chloride are treated with sodium thiosulphate. The solution of silver thiosulphate thus obtained is passed through settling vats and the silver is precipitated from the clear solution by sodium sulphide, the precipitate being filtered and shipped for refinement. The ore runs from 2½ to 3½% copper and about 7 oz. silver.

ALUMINUM SILICATE is an abundant constituent of many of the most common rock-forming minerals, and is an essential constituent of the mud, clay, shale, and slate which have arisen from the disintegration of these minerals. It has not yet been found possible to employ these materials as a source of the metal or of its useful salts. The most important aluminum minerals are bauxite and cryolite. The former, the chief source of aluminum, is a hydrated oxide of white or brown earthy appearance. It may be often recognized by a characteristic earthy smell, and positively determined by the blue mass obtained by heating with cobalt nitrate on charcoal. The latter is fused and used as a solvent for bauxite, from which solution aluminum is obtained by electrolysis. Cryolite, which means ice-stone, may be detected by its three rectangular cleavages and fusibility. If powdered and put in water, it is scarcely visible. The mineral is rare, the principal deposits being at Ivigtut in West Greenland, where it is associated with fluorite and pyrite.

THE use of soapy water as a lubricant for air-cylinders is recognized as good practice. Even where oil is used as the regular lubricant, soapsuds should be fed in from time to time to clean out the valves and discharge ports. There are many well-authenticated cases in which only soapy water is used as the lubricant. Soapsuds and Dixon's flake graphite mixed make an ideal lubricant for air-cylinders, for by the addition of graphite far less soapy water is necessary than would otherwise be required. Hand oil pumps will pass soapsuds and graphite perfectly satisfactorily, or the graphite may be fed separately in a dry state through a separate cup, while the soapy water passes through the regular lubricators. There is only one caution necessary in this method, namely, to introduce sufficient oil before shutting down the compressor to prevent rusting of the cylinders and valves when the machine remains idle. Rust, however, forms very much less rapidly in the presence of graphite than upon surfaces not thus coated—in fact, it cannot form at all upon a surface completely covered with a film of graphite.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Who Is a Mining Engineer?

The Editor:

Sir—The old question, "Why is a crow?" deserves to be bracketed with the above. We have the mining industry divided into various departments—copper, gold, lead, tin, zinc, iron, coal, etc., (with twenty more)—in which some people may overlap into half a dozen and some specialize over a part of one. Moreover, we have consulting engineers, mine valuers, general managers, superintendents, chief engineers, metallurgists, assayers, surveyors, inspecting engineers, etc., etc. A man may be all these or only one of them. The term engineer is applied to all of these in some connection or another, and the more specific term mining engineer to a great portion of them. They are really many different professions, but so closely allied that a man may slip from one to the other or be several at the same time. The general term does very well to describe oneself for jury duty, but in the industry itself we need to particularize a little. A step in the right direction would be to confine the term generically purely to men who direct actual mining works or mining investments as at least a portion of their profession, and not to include surveyors, assayers, or metallurgists. Most of the discussion has revolved around the question as to what training and experience or position a man should have in mining works before he is entitled to call himself an engineer. On this there is, to my mind, no finality. The term mining engineer is not a thing that belongs exclusively to those who have a degree conferred by some recognized institution. However, I have no sympathy for those who carp at college training as a basis for professional training. Of all the men that start in the profession, but few succeed, whether they come from the college side or the shovel side. My own impression is that a greater ratio of those who start from the college side succeed, and I have not yet met the successful man who came up through practical work who does not himself regret he did not have the college training. My personal experience is that I have met more 'practical' quacks than 'college' quacks. In any event, the test whether a man has the right to the title is purely a question as to whether he does good honest work in the direction of mining enterprises. Given any jury of men connected with the industry, I believe they would subscribe to the above as the only qualification for the profession.

No one can prevent men of immature experience or poor training from attempting professional work of this character, but the members of the profession do very generally set themselves against this type, and as a result the whole basis of professional qualification has been greatly improved.

There is one result that this discussion might have, and that is to stamp even more opprobrium on the sort of person who calls himself a 'mining expert.' This variety of a quack is very trying, especially when he bolsters himself up with a few letters after his name. Most engineers belong to various learned societies. To try to support one's standing by relying on their connection with such societies is itself a sign of a groggy position. Every member of these societies knows that they make little attempt to pass on qualifications of members. They merely publish professional literature. Dignified engineers never use such titles except in connection with such literary work, in which case it is eminently proper. Myself, I never employ or recommend men who seek a standing from the fact that they are an M. A. I. M. E.,

M. I. M. M., M. I. C. E., F. R. G. S., M. A., E. E., A. B., B. S., E. M., etc. or any part of it. Nor would I accept a report on a mine signed by such a person for more than a possible warranty for further investigation. And above all do I refuse all association with the 'mining expert.'

A LONDON INVESTOR.

London, October 12.

Who Is a Mining Engineer?

The Editor:

Sir—Several of my friends and acquaintances have verbally criticized my article published on October 6 on the grounds that I limit the term 'mining engineer' to college graduates who have also had practical experience. This impression arises from not taking my article literally and exactly, but by trying to read between the lines. As this is a quite general habit and as many have thereby got a wrong impression of my meaning, I think it only right to add to my previous remarks the statement that, as I understand the definition of 'mining engineer' given in the Century dictionary, there is no limitation placed on the method whereby a man may become "skilled in the principles" of mining. He may become thus skilled at college and he may attend college without becoming thus skilled. He may become thus skilled by taking a correspondence course or by simply studying by himself. There is one thing certain, however, that no man can comply with the Century's definition without being a *student* himself. The man who makes a success of mining by hiring other people's brains cannot comply with the definition of 'mining engineer.'

GEO. J. BANCROFT.

Denver, October 24.

Black Sand.

The Editor:

Sir—I am much interested in the article appearing in your magazine pertaining to the experiments now being carried on by Dr. Day and others, to perfect a method of extracting the values that are carried by the beach and river sands of this coast. I am a practical miner of some experience in different localities, and have spent two years investigating this matter. I am confident that some of these deposits are of sufficient extent with enough values to make the profitable working of them possible, if a successful method were found to separate the different metals. When the United States Government made a special appropriation of a large sum of money, placing the same in the hands of one of the heads of departments to be used to further investigation on this line, I expected that the problems would be solved. But while Dr. Day has satisfied himself and the miners that the values exist, we have not as yet received any encouragement to attempt operations on a commercial basis. The smelters give returns only on the gold which represents merely a part of the valuable contents. As at the mine in which I am interested the gold amounts to less than one-third of the whole, the fact remains that we are not one particle better off in this respect than before the appropriation was made. And I firmly believe that when we do attain success in this matter, it will be brought about by men that are directly interested in black sand; therefore I would like to have the assistance of your estimable journal in bringing the matter to their attention. I suspect that every difficulty that we have to contend with has been and is being overcome by individuals working independently. If we were able to take advantage of all the knowledge, experimental and practical, already gained, we could, I believe, perfect a practical working method. My experiments have consisted entirely of investigations into the most practical method of separating the black sand carrying values from the alluvial

deposits in the river channels, and I should be very glad to correspond with the readers of the MINING AND SCIENTIFIC PRESS that have spent their time working on the problem of extracting the metals from the concentrated sand, believing this would be of mutual advantage.

L. A. MAXWELL.

Crescent City, Cal., October 10.

[Mr. Maxwell's suggestion is a good one. There is nothing more useful than for men to compare their experience and to exchange ideas. It is this purpose that we try to promote every week in the MINING AND SCIENTIFIC PRESS.—EDITOR.]

The Geological Investigation of Orebodies.

The Editor:

Sir—It may seem trite to remark that in the business of mining there are many details either poorly managed or else not well understood. But all triteness may be eliminated by leaving the general for the specific, and there is one particular and fundamental phase of mining which yet needs much attention. This is the scientific investigation of orebodies for mine development. The statements to be made herewith come entirely from personal experience, while working, directly or indirectly, for mining companies in different parts of the country, and are put forth with a most sincere desire to aid, if ever so little, in placing the mining industry upon a firmer basis.

The numberless small mining companies, with an aggregate capital of many millions of dollars, are almost invariably ignorant, and therefore neglectful, of the basic importance of properly delineating and thoroughly understanding an orebody; and even the larger companies, with their corps of trained men, are too frequently lacking in this regard. The result is that not only is a vast amount of money spent needlessly, but legitimate mining is often dealt what is commonly called 'a black eye.' There are two distinct forms of this defect, concerning which, because the trouble lies at the very root of a large portion of the mining industry, it is hoped that a discussion may be initiated.

I have stood at the top of the head-frame of a certain California mine and counted, within a radius of a mile, six defunct 'mines' with hoists and accessories, each representing a loss of from \$25,000 to \$100,000. And, with a feeling of great impotence, I can at present discern several more in the making. Such a condition of affairs is indeed pitiable, and, being absolutely needless, it is a severe commentary upon the business sagacity of our capitalists. There are definite reasons why such a state of affairs is not necessary and it becomes the duty, as well as the business, of the mining engineer and geologist to act promptly in preventing such waste of energy and capital. Each one of the six properties just noted would have had no money invested upon it if a competent geologist and engineer had examined it at the beginning. But no; depending solely upon the word of a so-called 'practical' miner, who is able to tell good rock by looking at it, or at most by an occasional panning, the average aggregation of mine-mad capitalists puts up thousands of dollars in hard cash literally to sink them into the cold ground. The expenditure of perhaps a thousand dollars to find out what there is on the property is held to be a foolish waste; it is far more comfortable to work in the dark and have expectations. The ignorance of the average 'investor' is often amazing. A man who would never consider launching into business without first a careful inventory of goods, with every cent accounted for, and with all details fully worked out, will yet plunge headlong into a hole-in-the-ground proposition on someone's unsupported statement that good rock occurs there. And if

such a statement be reinforced by a specimen showing a little free gold, the would-be investor is completely hypnotized. If a mining engineer be of too serious a turn of mind, he is tempted to profanity; if he be properly philosophical, he will smile and be content to await the inevitable end. Well-meant, gratuitous advice is scorned.

But this is the more easily corrected and less insidious form of the evil referred to. The greater trouble lies in the development of a mine after it has become, if not a producer, at least a property with some ore blocked out. When an orebody has been partly opened up by the usual methods, it becomes far too easy for the foreman and superintendent to assume that the body is of a particular form and that as a consequence more ore is to be developed by a certain line of work. The slogan of the Angel's Camp region—"cross-cut!"—is a sample of this. Thus a set method of developing the ground is obtained, which is commonly not scientific in any sense, and is therefore unduly expensive. A simple quartz vein between well-defined barren walls is of course outside the limits of these remarks, unless the ore-shoots are peculiarly complex. But the mining fraternity as a whole has yet to realize fully that in general only a thorough investigation of a partially developed mine by a competent geological engineer can furnish the necessary data for future work. The well-worn saying that "gold is where you find it" is undeniably true as a logical statement, yet taken in the sense in which it is meant a great harm is done to the proper development of our mining resources, for it conveys an absolute untruth. We must not attempt to excuse ignorance by insinuating that something is forever unknowable. The kernel of the whole matter lies right here. The importance of real geological knowledge on the part of examining engineers is just commencing to have adequate realization. In the past it has been put aside as of secondary importance, and even then only a few of the leading geologic relations have usually been deemed sufficient. In the broad sense, geologic relations govern absolutely the formation of orebodies and it obviously is not right either to estimate the value of a mine solely by what ore is actually in sight or to draw up a plan of mine development without thorough geological study. Fortunately, the mining world is coming to appreciate this and one of the struggles of the future will be to have, not more geological work, but to have such work done by competent men. The fast growing science of the economic geology of metalliferous deposits has done much, and is doing more each day, to increase our exact knowledge of the occurrences of the precious metals, until now it is fairly possible to gather the facts necessary for their cheapest extraction. The time is ripe for the widespread inculcation of the idea that the business of mining, when entered into in a truly scientific way, is one of the most remunerative ways of spending money. And yet the vast majority of people look upon mining as a gamble, pure and simple. A few examples in outline will serve to illustrate the matter.

At Angel's Camp, where the only plan of mine development is to cross-cut, there are two principal geologic facts not properly recognized. First, there is the presence of fairly well-defined shear zones in the schist connected with the main quartz-bearing easterly dipping fissure below. The famous Utica shoot is of this type. Second, there is a series of northwest-southeast veins intersecting the foot-wall of the main lode at an angle of 40°. Neither of these facts has received proper attention, either as an aid to intelligent prospecting or systematic mine development. It is needless to state that a careful geologic investigation of the Utica shoot itself has never been made, and that thousands of dollars have been thrown away in useless work. The whole of the

Mother Lode region needs careful geological study. On the contrary, it can be said that at Copperopolis a study of the orebodies has revealed clearly the nature, place, and conditions surrounding the copper-bearing lenses. The Comstock lode was worked for years in the most expensive manner because the exact nature of the orebodies was not understood.

Here again, the idea of 'verticals' has never been accepted as a basis for mine development. And today many promising properties throughout this western region stand idle because of lack of proper geologic investigation to guide exploratory work. Until a few years ago it was the privilege of the miner to lead, the geologist to follow. And geology suffered as a natural result. But this relation no longer holds true, for with the rapid advance of research work into mineral deposits, the geologist can justly claim leadership, if he will. Therefore, it is time for the properly trained scientist to tell the miner what to do and how to do it when opening up an orebody. The whole future of truly scientific mining rests right here.

JOHN A. REID.

Stockton, Cal., October 29.

Position of Amalgamating Plates in the Stamp-Mill.

The Editor:

Sir—The letter in your issue of September 29 by Mr. Percy Morgan, recalls experiments made by me some years ago. The mill had 20 stamps, with eight 6-ft. Frue vanners and a Gates slime-plant below it. The ore was a heavy sulphide, with a very low content in free gold.

The existing plates consisted of four 48 by 144 in. silver-plated copper plates, set below the batteries in the usual manner, with a grade of $2\frac{1}{2}$ in. per foot. As it was necessary to elevate the pulp to the vanners, the point was considered of installing the plates above the battery-floor, thus leaving the space around and in front clear. As an experiment, one of the plates was placed away from the mortar, the pulp from five stamps was elevated and taken to this plate through a launder with a grade of four inches per foot. The plate was set first with a grade of $2\frac{1}{2}$ in. per ft., but this was found to be insufficient to clear it properly, so the grade was increased to three inches, and later to $3\frac{1}{2}$ in. per foot.

Under these conditions the plate was run for thirty days, samples being taken every fifteen minutes, by hand, from the mortar lips and from the tailing-trap. Samples were also taken from the other three plates, in the same manner and from the same places. Even with the grade given, it was found necessary to add more water to the head of the experimental plate than the pulp contained when discharged from the mortar. Ratio determinations were made from time to time to learn the extent of this addition. It was found that 8.4% more water was used on this plate, and that the amalgam recovered was 3.8% less, but 1.2% was later recovered in the launder leading to the plate, so that the deficiency amounted to only 2.6%. The excess of water gave considerable trouble on the two vanners fed over this plate and increased the value of the vanner tailing from 7.2 to 9% of the heading sample.

The operation of this plate was not at all satisfactory, the pulp lacked the wave it formerly received from the mortar, and instead of the heavier particles being forced down the plate by successive pushes, as is quite noticeable on the plates before the mortar, it ran over the plate at a much greater velocity; further, a greater proportion of the amalgam was caught on the lower section. After the above results it was decided that the proper place for plates was below the mortars, and it is my opinion that

when perfect amalgamation is desired the place for the plates is below the mortars.

CLIFFORD G. DENNIS.

Terlingua, Texas, October 20.

DIVERTING BATTERY-DISCHARGE DURING CLEAN-UP.—Fixed to the top of the chuckblock, immediately beneath the screen frame, is a sheet-iron catch-plate 8 in. wide, which deflects the pulp outward, enabling a satisfactory screen sample to be taken. In ordinary running the pulp falls from this catch-plate to a baffle-board, which deflects it back on to the lip of the mortar. When the plate is to be dressed, this baffle is removed, and a sheet-iron launder is substituted. This rests on chairs fixed to the sides of the table-frame, and serves to catch all the pulp from the catch-plate and carry it to one side of the plate. The pulp then falls into a portable launder 14 ft. by 6 in. by 6 in., down which it runs into a permanent launder situated under the working platform at the bottom of the plate. This permanent launder runs the full length of the mill and discharges into a distributing box placed at the head of an extra plate 5 by 12 ft., situated outside the mill.

When a plate is to be dressed, the amalgamator first puts the portable launder into position, one end resting on the extra launder under the platform, and the other resting on a support on the king-post. He then lifts the sheet-iron trough into position, and the pulp forthwith flows to the extra plate outside the mill. A piece of canvas is hung over the screen to prevent splash, and two pieces of sheet-iron are pushed into saw-cuts in the screen frame at each end; these serve to throw the pulp delivered at the corners of the screen frame toward the centre of the catch-plate, thus preventing splash and leakage on to the main plate at the corners. These sheet-iron plates do not reduce the screen area at all. No wedges or fastenings are required, and the weight of the portable launder and the sheet-iron trough are negligible.

The scheme has proved perfectly satisfactory in every way, the main plate being quite dry and clean during dressing and steaming, and the labor involved in fixing the gear being nothing. The extra plate behaves quite normally, though as it only runs 4 hours 20 minutes per diem, I consider it advisable to use copper that was already 'set.' This plate has a lock-up cover, it is dressed each time immediately before dressing the main plates. The running time saved in this mill for dressing plates, by using this gear, amounts to 8 days 8 hours per annum, plus 18 hours for steaming, making a total of 9 days 2 hours, which in our 40-stamp mill means 1,816 extra tons crushed at no extra cost for labor.—R. Weston in *Journal Chem., Met. & Min. Soc., South Africa*.

AN undertaking of unusual magnitude in land re-claiming has lately been investigated by the Belgian Government. It is proposed to lay dry the great basin of the Zuyder Zee, which for the last 800 years has been flooded to a depth varying from 10 to 20 ft. The area, 5,250 sq. m., is one-sixth of the size of Holland. A dam is to be built nearly 20 miles long, having a breadth of 30 ft., at a height of 18 ft. above sea-level. On this it is proposed to build a wagon-road or a double-track railroad, the whole undertaking costing about \$60,000,000. The Hollanders are unrivaled in reclamation work and it is probable that their immense experience will in due time permit them to acquit themselves brilliantly in this great undertaking, which has been so long discussed.

THE great prizes in mining are realized by those who take the risks, when the mines are not greatly developed, and consequently when they do not have much ore exposed.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

Under the statute requiring that a notice of the location of a mining claim be posted at the point of discovery, and two conflicting claimants posted notice at the same point, it was decided that this fact, in absence of evidence to the contrary, warranted the presumption that both based their claims of discovery on the same natural conditions, and that, therefore, a discovery of mineral actually existed.

Fox v. Myers (Nev.), 86 Pac. 793.

Where a mining company bought a 'Huntington mill' of the 'latest improved' patent for the reduction of ore, it was held that there was no implied warranty of fitness for the purpose intended, though the seller was informed of its intended use.

Mine Supply Co. v. Columbia Mining Co. (Ore.), 86 Pac. 789.

Under the statute providing for priority of location rights on the discovery of mineral in the public domain, it was held that a locator had made a discovery when he found rock in place containing mineral in sufficient quantity to justify him in expending his time and money, whether the rock or earth is rich or poor, provided that in a lode claim the lode must have special reference to the formation and peculiar characteristics of the particular district in which it is found.

Fox v. Myers (Nev.), 86 Pac. 793.

Where a seller of mining machinery sold a 'latest improved Huntington mill,' but furnished a mill of an old style, there was a breach of contract, and the fact that the purchaser accepted and made an effort to use the mill was not a waiver of his right to damages for such breach, and the measure of damages was the difference between the value of the machine agreed upon and that of the one furnished.

Mine Supply Co. v. Columbia Mining Co. (Ore.), 86 Pac. 789.

Under the statute of California where notices of location of a mining claim recited a location 1,500 ft. of 'this vein or lode of gold-bearing rock,' etc., it was held that such recital indicated that the notice so posted on the ground was posted on the croppings of the lode, or in such close proximity thereto that the croppings appeared or had been exposed.

Daggett v. Yreka Mining &c. Co. (Cal.), 86 Pac. 968.

The mere introduction of a map in evidence in a controversy over the location and description of a mine which purports to show the lines of the location of the claimant, was held to be of no value, where such map was not supported by evidence which defined the lines, and which departed widely from data established by the best evidence the claimants could offer to prove the original location of their claim.

Daggett v. Yreka Mining &c. Co. (Cal.) 86 Pac. 968.

Where an agent in obtaining an interest in a mine for his principal, and aids in securing a patent, knows of the existence of contracts and interests of other persons in such mines, this knowledge of the agent is imputed to his principal.

Carter v. Gray (Ark.), 96 S. W. 377.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The two rocks from Los Angeles, marked F. G., are rhyolite-porphry.

Rocks from Beowawe, Nev., marked O. B. A., are: No. 1 and 2. Rhyolite; No. 3. Andesite.

Samples from G. E. W., of Los Angeles, are rock-soap or soapy clay, a hydrous silicate of alumina, but the composition varies.

The rocks from Berlin, Nye Co., Nevada, are: No. 1. Epidote; No. 2. Garnet; No. 3. An altered aluminous rock incrustated with halloysite; No. 4. Impure magnetite.

The specimens from J. B. G., of Dragoon, Ariz., are: No. 1. Quartz, the brown color being due to the oxide of iron; No. 2. Quartz and limonite with a small amount of yellowish lead carbonate in cavities.

The dark mineral in the specimens from Gibbonsville, Idaho is limonite (iron oxide); no tinstone in any of the pieces. The yellowish-gray pieces are aluminous-rocks—probably altered dike rock of some kind.

Rocks from Weiser, Idaho, marked E. W. S., are: No. 1. Decomposed slate; No. 2 and 3. Decomposed granitic rock; No. 4. Silicious limonite; No. 5. Mixture of garnet, feldspar, hematite, quartz, and chlorite, presumably a gneiss; No. 6. Quartz; No. 7. Schist with vein of dolomite containing pyrite and a coating of yellowish brown limonite.

The rocks from Callahan, Cal. marked C. O. T. are: No. 1. Quartz, semi-crystallized. It seems to be nothing out of the ordinary, greatly resembling the white half-crystallized quartz usually found in gold pocket mines of California. No. 2 is a fine granular quartz rock stained dirty grayish green by chlorite and copper carbonate. A little copper-iron sulphide is disseminated in the rock.

The ore from Salt Lake marked L. M. & M. Co. is quartz containing probably 20% iron sulphide, the greater portion of which is so finely disseminated as to appear amorphous. The ore is in a state of semi-decomposition and contains sulphates (iron and lime). Carbonate of lime is also abundant as a white incrustation. The bright metallic surfaces of pyrite are caused by movement within the rock, causing slickenside.

COAL IN ALASKA.—At present the enormous coalfields of Alaska are hampered by lack of transportation facilities, but the disadvantage will be removed partially in a few years, when the present program of railroad construction is completed. The Bering river coalfield near Controller bay, on the Pacific coast of Alaska, includes 25 miles of anthracite and 45 miles of semi-bituminous coking coal. The seams are numerous and very large, several exceeding 20 ft. in thickness. The Matanuska river coalfields, from 30 to 75 miles northeast of Cooke inlet, cover an area of at least 75 square miles. These deposits, which also include anthracite and semi-bituminous coking coal, will soon be tapped by the Alaska Central railway making connection with Resurrection bay on the Pacific coast. No comparison can now be made as to merits of these two coalfields as so much depends on the peculiar local conditions. The high percentage of fixed carbon (about 81%), low ash, and sulphur contents give these districts the essentials for development in future years into valuable mining properties.

Three Weeks in Mexico---X.

Pumping Methods at Pachuca.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

Near the summit of the ridge, at Hiloché, where the Pachuca road descends to Real del Monte, there is a fine grove of primeval oak, suggesting the forests which covered the plains and hills of Mexico before the Spanish conquest. A good purpose is shown in the young plantation of cedar and eucalyptus that has been started in this locality. Mexico has suffered enormously from de-forestation, and the laying out of trees ought to be one of the first duties of the Federal and State authorities, as well as of public-spirited citizens. At Hiloché is the big pavilion built in 1901 for the entertainment of 600 people, constituting a party of the American Institute of Mining

The pump was installed on July 23, 1905; it has four compartments, alongside, the water being forced from one into the next, each pump re-inforcing the other. It is operated by a 650-h.p. motor working with 380 h.p. and was taking about 4,000 litres at the time of our visit. The motor of this rotary pump was supplied by Brown Boveri & Co., of Baden, and is of the three-phase induction type. It is constructed to yield 650 h. p. at 60 cycles or 900 rev. per min., using 160 amperes at 1,100 volts. The pump-shaft is coupled direct to the motor-shaft. The motor was running at only two-thirds its normal speed, yet it was heating rather badly; this is characteristic of most Swiss motors. Although Swiss and German motors are cheaper, they have got no stamina and will not stand an overload like the American-made machines, some of which are actually guaranteed to carry an overload of 25 per cent for two hours or even longer. No suction is used, the pump draws from a dam that affords a 50-ft. head.

The Plaza at Pachuca.

Engineers. That occasion is remembered by a great many who are now scattered over the mineral regions of North America. The pavilion has not been demolished; it is used for picnics.

Descending by a winding wagon-road we soon reached La Dificultad, at an altitude of 2,793.27 metres. This mine is one of the chief openings of the Real del Monte company. It affords, among other things, an interesting example of pumping practice. In the shaft-house there is an enormous engine of the marine type built by Richard Hartmann, of Chemnitz (Austria) in 1889. This operates two stationary Rittinger pumps, with 890-mm. discharge and 2.5-m. stroke; also a sinking pump of the same kind with 850-mm. discharge and 3-m. stroke. The capstan engine for handling heavy pieces of pump and facilitating repairs is from Tangye, at Birmingham (England). These pumps have been replaced recently by a new Swiss pump, but they are kept ready in case of need. The Swiss pump comes from Sulzer Bros., at Winterthur; it has a capacity of 8,400 litres per min. to a height of 240 m., delivering the water from the bottom, at 540 m., to a drainage level at 300 m. below surface.

The pressure in the column is 25 kilo. per cm. The sump under the rotary pump is three metres deep, the water from it being raised to the dam by a Knowles pump geared to a motor which gets its impulse from a Koerting elevator, operated by a stream of water descending from the 300-m. level. These Swiss centrifugal pumps are used in other mines at Pachuca and they are said to be highly satisfactory; they have a particular arrangement of the runners which is effective; the makers of them are willing to guarantee a specific efficiency, which, as yet, American manufacturers will not do. Four of these Sulzer pumps (each of 1,500-gal. capacity) have been ordered for El Oro mill, to raise the return water and solution from below the zinc room. At the pump station there was the usual shrine with lighted candle on each side, and ornamented with artificial white flowers.

The first 50 ft. of the shaft is lined with masonry supported by arches sprung from the country rock. The shaft is not continuous; from the 440-m. level there is a counter-shaft to the bottom. This is descended on a cage with steel-rope guides. At the 440-m. level there are

some large underhand stopes; when the flat cable is worn out, its separate strands are used for hoisting ore underground, in hides that hold 25 kilo. each. These are not made in the shape of buckets, but they are laid flat, the broken ore is put on them and then they are laced so as to make a parcel. The ore hoisted by windlass in this way is discharged into side-dumping cars, which are run on a wooden track lined with an iron band, to the station at the shaft, where it is dumped onto a platform to be shoveled into a skip. Altogether, it afforded a curious mixture of old and new methods; it was a hybrid practice. At the 463-m. station we changed from the counter-shaft to the main shaft, and while waiting for the cage we watched some men who were loading the accumulated

by iron gates, so as to prevent pilfering of ore. There is no timbering worth mention. The ore is mainly quartz; it is often ribboned by the banding of rhodonite and sulphides (iron pyrite and argentite); on the whole it reminds one of the veins in the Alice and Lexington mines, at Butte, Montana. The accompanying sketch of the Santa Inez vein is a fair example of the lodes in La Dificultad mine. Both walls are well defined; on the foot (*G*) there is a wet slip; *E* is a band of rhodonite; *D* is mainly amethystine quartz; *F* and *B B* are sulphide streaks; *A B* is massive poor quartz; *B* to *C* is mottled by brecciation; between *D* and *E* there are streaks and spots of sulphide, including argentite, a little galena, and occasional yellow zinc-blende; *E F* is brecciated andesite,

A Mexican Ox-team.

waste into ox-hides; these held 300 kilo., or the third of a ton, and after being laced they were hung by chain to the bottom of the cage, the material being used at the next level for filling. All the rock broken in shaft-sinking is raised in this way, and even water, just as they did in

the days of Pedro Terreros. As the five men filled and then laced the raw hide, they put it aside for the next trip of the cage; when I first saw it, I thought it was the carcass of a dead mule, and it smelt like one.

In walking through the workings, one notices that the cross-cuts are walled up, the walls being often sealed with clay to direct the ventilation. There is a good deal of masonry in the mine, and different parts of it are shut off

now partially silicified; *F G* is crushed quartz. The whole width of lode is seven to eight feet. At the Dificultad mine, the low-grade ore left on the dump is said to contain 400 gr. silver and 2 gr. gold. This affords an idea of the cost of working. At the Barron mine, the ore is said to average 800 gr. silver and 4 gr. gold, while in the Dificultad it is said to carry, for an average of eight metres, not less than 1 kilo. silver and the usual proportion of gold.

It may be added that the prevailing formation about Pachuca is andesite; the veins are lines of fracture which have been healed by silicification. There exist in the district several islands or caps of basalt connected with vents and there are dikes of rhyolite accompanied by slight mineralization along their walls. For details of the geology, the reader is referred to a valuable paper by Señor Ezequiel Ordoñez.*

On leaving Real del Monte by the southern road, one obtains a good view of the surrounding country, by looking back. To the left is a rounded ridge clothed with groves of oak; to the right, a conical hill surmounted by a copice of dark oak and cedars of Lebanon, and under their shade the white-walled English cemetery where many a Cornishman has gone underground for the last time. Between these flanking hillslopes, framing a pic-

*The Mining District of Pachuca, Mexico, *Transactions Amer. Inst. Min. Eng.*, Vol. XXXII, pp. 224-241.

ture, there are the white houses and red roofs of the town, surmounted by Moorish church-towers, among which, curiously out of place, is the Cornish engine-house with its lofty chimney rising above the castellated enclosure of La Dificultad mine. Behind the town are green hillsides, and further back, after the interval that marks a deep *barranca* or gorge, there stands, outlined against the blue sky, the mountain which is crowned by the battle-mented rocks of Zumate.

When the road crosses the summit and begins the long descent to Pachuca, there is much to be seen that typifies the Mexico of today. The broad and winding road cuts through gray-purple andesite; it is lined with massive stone culverts and does credit to the engineers responsible for the construction. It skirts brown hillsides, darkened in spots by the wild *maguay*, whose tall central stem is the sign of an uncultivated condition; there is an occasional cactus and a few palms, mainly the *izote* from the fibre of which are made the straw hats of the *peones*. Whitewashed monuments dot the surface and, in their occasional sequence of direction, mark the boundaries of mining property. Yellow scrub fringes the road and enhances the value of the purple in the distance. A flock of sheep, a string of patient donkeys laden with charcoal from the forests, other *burros* coming from the valley and laden with pigskin bags inflated with their burden of *pulque*; some sad-faced Indian women trudging up hill, one of them with a baby slung in her *reboso*, another walking patiently while her man rides alongside on his mule; then a cavalier with wide *sombrero* and gaily caparisoned saddle, a *serape* thrown over the silver-mounted pommel and riding his horse superbly; a wagon heavily laden with sacks of ore, its brakes crunching noisily, drawn by ten mules, with silver bells, and driven by a brigand-like muleteer—all these are part of the stream of life that we pass or meet on that road. But the foreground is not all the picture; at our feet, to the south and west, lies outspread the vast plain known as the valley of Mexico, crossed by white streaks of dusty road, checkered by squares of cultivation, the yellow patches of maize, the green of barley, and the occasional darker shade of alfalfa, with other rectangular lines that mark the serried rows of *maguay*.* Sunlight and shadow shift over the vast expanse; in the distance, more than 16,000 ft. high, rises the snow-crest of Ixtaccihautl—‘the white woman’—partially veiled in a cloud, and by the Aztec name recalling the pathetic fate of an ancient race. In middle distance there is a blue ridge behind which is Mexico City, and to the right, under the mountain of San Christobal, hides the dusty town of Pachuca; in between are several famous mines—Corteza, El Lobo, Santa Gertrudis, Barron, and La Blanca—each in its walled enclosure and dominated by a towering shaft-house of stone. And then, before we realize it, we are awakening the echoes of the narrow streets of Pachuca, and amid the crackling of our *cochero*'s whip and the shouts of those who get out of our way, we pull up at the railway station just in time to catch the train for Mexico City.

THE mechanical equivalent of heat has now been determined with an accuracy of one part in 2,000. At Greenwich, England, 777.7-ft. lb. is the equivalent of the amount of heat required to raise one pound of water through 1° on the hydrogen scale at 63.5° F. Our advance in scientific knowledge is a function of accurate measurement.

*There is no *maguay* on the west coast of Mexico, only one-tenth of the population of the entire country drink *pulque*, chiefly in Mexico City and its vicinity, including such mining towns as Pachuca and El Oro. It is unwholesome because it is drunk when still in process of fermentation; if the people did not take this stimulant they would take some other.

The Reduction of Quicksilver Ore.

Written for the MINING AND SCIENTIFIC PRESS
By FRANK J. BOOTH.

Scattered over the quicksilver districts of San Luis Obispo county—and I mention these districts merely through more thorough acquaintance with them rather than with any idea of comparison in mind—lie the deserted and dismantled remains of half a dozen pipe-retort furnaces, the bleaching bones of the last revival of quicksilver mining in that district. With the cooling of the pipes at the Little Bonanza mine recently, retort reduction ended in that district. It will probably remain so until another rise in the price of quicksilver adds new vigor to a rather disheartened industry.

Although, in the none too extensive literature on the metallurgy of quicksilver, the system of pipe-retort reduction has been largely ignored, still the large number of practical applications of it certainly warrant some discussion. This contribution is intended to be merely a general criticism, based on a working experience with retorts, and is written in the hope that it may possibly prevent some of the disasters in the future that have so characterized its application in the past.

Low in cost of installation, the pipe-retort is fundamentally a prospector's plant, and as such, even with its low capacity and high cost, it is efficient. With but few doubtful exceptions, it has never been operated successfully as a permanent reduction system. Even in these exceptions, the success has only been relative, since the ultimate profits would probably have been greater with other reduction methods. As but few gold mines can long stand the drain of an *arastra* as a crushing machine, so even fewer quicksilver mines can long endure a retort system. Both involve the sacrifice of all the low-grade ore in the mine, in order that the high-grade ore may be worked, at a higher expense than if all of the ore were worked together.

Retort reduction is essentially a simple distillation, in which the mercury vapor is kept separate from the flame and smoke of the fire-box. This is the chief difference from the principle of furnace reduction, where all the gases enter the condensers together. The isolation of the mercury vapor greatly assists its liquefaction by reducing the volume of gas nearly five times, and simplifying its composition.

Theoretically, retort reduction should have perfect efficiency, but this is never reached. Few operators have any idea of what their recovery is, but it seldom exceeds 75%. The plant is operated by one man who must do heavy, disagreeable work, and at the same time be keen and experienced enough to understand his retort and keep the heat, charges, and condensers properly regulated. The difficulty in finding and keeping such men on the job is its greatest drawback, and the chief factor in its efficiency. The steam from moist ore interferes with condensation by heating the condensers and some ores burn more easily and better than others; all of which influence the success of the operation.

The efficiency and capacity of a retort are linked together and are dependent on many of the same factors. In ordinary practice retorts are built with 12 pipes, one of which is charged every hour, thus allowing the charge to ‘burn’ for 12 hours. Some highly pyritic and rich ores will not burn out in this time, and are left for 24 hours. The unburned ore or a ‘green’ charge is easily detected in the daytime by white fumes about the mouth of the pipe and on the lid, and at night by the pale blue flame of sulphur and mercury. The ordinary charge is 125 lb. per pipe, or about 1½ tons per 24 hours for the retort. This charge is dependent on the heat maintained, richness of ore, character of ore—as to sulphur,

size of pieces, and amount of moisture—and must be determined by practice in any case. Sometimes the addition of lime, ashes, or iron borings will assist the burning by taking up the uncombined sulphur. The pipe is usually only filled about one-third full, thus leaving sufficient air to take up all the sulphur resulting from the breaking up of the cinnabar. Highly pyritiferous and very rich ores will produce an excess of free sulphur thus:

Quicklime is the best absorbent for this, thus:

In case of uncombined sulphur remaining in the pipe,

draft by allowing the grates to choke rather than by use of dampers. A deep ash-pit kept nearly full of ashes and coal heats the air before admitting it to the fire-box, and will save much wood. A low slow heat is superior to a high one burning the ore quickly, both as to the recovery of the mercury and the life of a retort. I have seen a bench of twelve pipes burned out in two months, and again I know of others that are in fine shape after two years' continuous use. Theoretically, the heat should not go much above 400° C., cinnabar distilling at 375°. In practice the ore should show red in the back half of the pipe by daylight, barely showing any red when falling from the pipe to the wheelbarrow. At night the pipe

should show a strong red from end to end, but never any white heat.

Usually the retort consists of 12 independent units all heated from one fire-box. These units are cast-iron pipes six feet long, with an eight-inch bell at one end and an opening at the other to receive the condenser pipe. They are usually 10 in., inside diameter, and 11¼ in. inside

Fig. 1.—Retort Furnace for Quicksilver Ore. Cross-section.

it will re-combine with the mercury as cinnabar about the entrance to the condenser pipe and, in extreme cases, choke the latter.

Perhaps there is no part of the retort so vital as the fire-box, and no factor in the efficiency more important than the heat regulation; and certainly no part of it is

the bell. They weigh from 500 to 700 lb., according to thickness. The open end is sealed by double lids, luted on with moist ashes and held tight by bar and wedge. The pipes are laid parallel and level across the length of the retort. The fire-box is placed at one end, the heat passing under the pipes through seven parallel flues and

Fig. 2.—Retort Furnace for Quicksilver Ore. Front Elevation.

more abused and less understood. Most retorts have fire-brick grates, and, where these are carefully constructed of arched brick and securely tied to prevent spreading, they are superior to iron grates. Still, in practice, they are seldom able to stand long under the rough usage they receive in firing with crooked, heavy cord-wood. I have used grates successfully, but they are easily burned up by lack of care in raking them. The retort requires a slow draft for burning fuel economically, and there is great temptation for firemen to cut down the

returning over them through two arched flues, thus traversing the length of the retort twice before reaching the stack. The retort is usually divided into two separate sections, front and back, and the heat can be thrown from one to the other by means of dampers in the two upper flues. The pipes are charged with an iron scoop holding 30 lb. of ore and emptied or 'drawn' with a semi-circular hoe directly into an iron wheelbarrow. The condenser pipes are cast-iron, eight feet long and three and one-half inches outside diameter, fixed into the

end of the retort-pipe by a rust joint (sal-ammoniac and iron filings). They are usually given a fall of about 1½ in. per foot. These condenser pipes all feed into one trough, in which the mercury collects and is drawn off every day. The best trough is made from a 'bull pine' log about 12 ft. long. In ordinary practice, a piece of heavy burlap is thrown over this trough and the ends of the condenser pipes. This practice is bad, however, and wasteful as well as unsafe for the retort-men. Still it must not be condemned entirely because the retort at best is a prospector's plant and is often built where lack of water makes good condensation difficult. Many substitutes have been used for the burlap. These usually take the form of closed boxes or chambers of wood or brick, and where water can be used to keep them cool, they are successful. The condenser pipes are kept clean of soot, mercury, and water by means of a small hoe on a flexible steel bar.

This is the ordinary form of the retort, but there are many variations from it. Different conditions—finances, water supply, character of ore and wood, and hobbies of builders—have given birth to as many patterns of retorts as there are of stamp-mills. Some have double fire-boxes, 10 and 20 pipes instead of 12, etc. Some retorts are built with semi-circular pipes instead of circular ones. These economize space and increase capacity, but are more expensive (costing \$200 instead of \$25), and have but questionable advantage over the round pipe.

In its usual form the retort costs from \$1,000 to \$1,500, depending on freight, cost, and accessibility of materials. The pipes are usually worth from \$25 to \$35 apiece, according to weight and thickness. About 6,000 red brick and 2,200 fire-brick with fire-clay are needed in the body; 150 ft. of lumber and 150 ft. of iron rods are used for bracing. A good mason and two helpers can build a retort in ten days.

Two men, each on duty 12 hours, are needed to operate the retort. They are usually paid \$2.50 or \$3. The work is disagreeable on account of the heat and fumes of sulphur, but is not especially hard. One man can charge and fire two retorts and not work more than 25 minutes out of each hour. Since the capacity of a plant can be doubled without extra labor cost, retorts are usually built and operated in pairs. From 1¼ to 2¼ cords of four-foot wood, according to the kind, are used by two retorts every 24 hours. Running expenses will amount from \$10 to \$15 per day. The production depends, of course, on the richness of the ore. Saving 75% of the quicksilver in three tons of ore, it amounts to

½% of ore.....	\$11.25
1 % " ".....	22.50
2 % " ".....	44.50
5 % " ".....	112.50

at the present price of quicksilver. Some mines have paid for all their development work from the returns of two retorts, but many mines have been fairly gutted by attempting to run retorts too long.

There is but little more danger from mercurial poisoning or salivation about a retort than any other reduction system. This danger is reduced to a minimum when both men in charge are careful and experienced. New men almost always feel the silver before they realize the necessity of doing their work as it should be done.

With ordinary care a retort burning ore alone ought to last indefinitely, save for the necessary wear and tear on the masonry of the fire-box and about the pipes. In soot retorts and where very high heat is maintained, pipes are often 'burned up' until they leak.

An owner of a quicksilver prospect, having little capital, is usually tempted to install a retort to pay for

the development of his property. Where this can be done without injury to the mine, it is a wise move; but where large orebodies of medium-grade ore must be gouged of their rich pockets, it seldom pays in the long run. Where the ore is hard and breaks into pieces instead of crumbling, it can be sorted by hand until it will pay well. In such a mine the ore from development work will often keep the retorts supplied. If the ore cannot be hand-sorted, unless it is very rich—averaging three or four per cent—a retort should never be installed. An owner must know his mine and realize the inadequacy of a retort before he builds it, or he is liable to lose his money and ruin his mine as well.

HYDRAULIC SURVEYING FOR MINES.—The miner's unit for measuring water is the 'miner's inch.' By an inch of water was originally meant such continuous flow as will go through a one-inch square hole, the head of water behind it being usually six to nine inches. This very loose definition has been done away with, but the name still applies, being defined more exactly as ninety cubic feet of water per hour (1½ cu. ft. per min.). In spite of all criticism, the miner's inch has become by custom the standard unit for the flow of water in most mining districts. It no doubt retains its hold on the practical mind because no good definite time or capacity units are in general use, seconds, minutes, hours, and days, or gallons and cubic feet with their clumsy relations to one another, being used according to the whim of the individual. To get an idea of the magnitude of a standard miner's inch, it may be remembered that it is equivalent to a stream one inch square running at a uniform rate of 3.6 ft. per second. This is about a medium speed for small mountain streams; and, with a little practice, the flow of such a stream in miner's inches may be calculated mentally, after rough measurements have been made of the cross-section of the stream and the speed of flow of the water at the surface. The accuracy of this process is within the ordinary limits of fluctuation of the stream from day to day. If the flow has to be recorded over a long period it is well to put in a weir.

For estimating the flow of larger and more important mountain streams, a portion of the stream where the width and flow are comparatively uniform may be chosen and the length of this portion measured and marked by flags. A cross-section of the bottom of the stream is obtained at each flag, and at intermediate points if necessary, by measuring the depth at equal intervals across the stream; from these a mean cross-section is obtained. Floats are started at intervals across the stream opposite the up-stream flag, and timed with a stop watch while running to the down-stream flag; the speed of each float represents the velocity of the stream in its respective longitudinal strip. Each velocity is multiplied by the area of the corresponding portion of the cross-section of the stream, and from the total flow so computed a certain percentage is deducted for the excess of surface over mean flow; this, for ordinary mountain streams, is approximately twice the percentage of the grade of the channel.

The surveying and staking out of mining ditches, flumes, and pipe-lines follow the general practice for this work in other fields of engineering.—From 'The Principles and Practice of Surveying', by Breed & Hosmer.

THE progress of physical science is largely due to the fact that men have gradually learned to lay aside the consideration of unverifiable hypotheses; to guide observation and experiment by verifiable hypotheses; and to consider the latter, not as ideal truths, but as a symbolical language, by the aid of which Nature can be interpreted in terms apprehensible to our intellects.

Metallurgical Accounts.

Written for the MINING AND SCIENTIFIC PRESS
By PHILIP HENRY ARGALL.

The accountancy necessary for a smelter presents difficulties and complications possessed by few other industries. This is due probably to the great amount of figures required and to the fact that such bookkeeping must, so to speak, be double-barreled, a complete system being necessary for the financial portion, and an entirely different one for the metallurgical part, although the former is dependent upon the latter in every detail. The former which comprises the usual phases of ordinary accountancy, need not be described, save as it may come in touch with the metallurgical system, which ultimately must be incorporated in the financial accounts of the company.

The metallurgical accounts of a smelter serve the same purpose with regard to ores and their contents as the financial accounts do with regard to the finances. They show the loss or gain in metals, liabilities and assets of actual quantities of metals received in the ores, the cost of smelting, and of refining per ton, that of parting per ounce; thus affording a comparison of costs and tonnage treated from month to month; of one period with another; and they give an approximate record of each day's work and expenses.

To do this requires a system complete, yet simple and it is in this particular that, perhaps, the great difficulty is encountered. No matter how one may cut and prune and modify, the metallurgical system of any company must, to a certain extent, be cumbersome, and unlike most other instances of 'red tape,' it tends to facilitate methodical work. One of the most important items in the whole system is careful and systematic checking. The necessity of this will be easily understood by a casual glance at the various forms submitted hereafter, many of which are designed so that when the statement is finished the results check themselves; should they fail to do so, there must be something wrong, and the work must be gone over again.

Assuming that we have a complete lead plant for smelting ore, refining the products of the blast-furnaces, and parting the material which comes from the refinery, the question arises how can the cost of each process, or department, be arrived at, and what is the cost of producing the refined products? also, what gain or loss has been made in the gold, silver, lead, and copper shipped, as compared with the quantity paid for on the assays of the company?

With this end in view it is necessary to make divisions, or departments, which are in turn divided and subdivided, under respective headings. Naturally, the first separation is into: 1, Smelting; 2, Refining; 3, Parting. Each department must stand on its own merits, otherwise the results obtained are worthless. If a shipment be made from one department to another, credit should be taken by the department sending it away for the value and total contents as determined by assay, as would be the case if the shipment were made to another company. The department receiving the consignment would accept a debit for the value and contents, but would credit itself with a certain fixed amount for treatment, which would be charged against the department shipping it. Of course, some of the metal contents are returned from one department to another for re-treatment, but that would not affect the first shipment. The department returning such contents in the form of a by-product would get a credit for it in turn, and the department receiving it would accept a debit, but, as in the first case, a certain amount would be charged against the department making the shipment to cover cost of treatment. In this way metal losses in each department would

appear against that particular department, and would not, as when treated differently, show against some other part of the plant.

SMELTING.—Under this heading would be shown:

1. Cost of ores sampled.
2. Proportion of labor employed from the time the ore is received until the contents, in the shape of base bullion, are delivered to the refinery.
3. Tools and supplies for handling and treating such ores until their metal contents have been delivered to the refinery.
4. Cost and maintenance of machinery used directly by the smelting department.
5. Proportion of power and lighting used for treating and handling ores until their metal contents have been delivered to the refinery.
6. Roasting, including labor, fuel, etc.
7. Briquetting, including labor, fuel, lime, etc.
8. Smelting.
9. Proportion of miscellaneous and general items used in common by the whole of the plant, such as insurance, watchmen, fire service, tracks, runaways, etc.

The less these sub-headings are again divided the better, as the more they are split up the greater the complications and the more probability of error. However, as it is necessary to ascertain the cost of sampling, the cost of roasting, briquetting, actual smelting, etc., further subdivisions must be made, which will be taken up later in connection with Labor, Time-keeping and Stores.

The following plant forms and statements are proposed for use. On receipt of ore it is, of course, weighed by the sampling foreman, and particulars, such as car number, name of consignor, gross weight, number of bags, tare, net weight, class, etc., should be entered in the Inward or Receipts book, and a carbon copy, which should be taken of each day's receipts, sent to the office first thing every morning. A form suitable for this purpose is shown in Fig. 1.

For use in the office, and for making settlement, the sampling foreman should also fill in part of Fig. 2, for each individual lot of ore. The weights, lot number, number of bags, class of material, marks, name of consignor and car number would be filled in by the sampling foreman; the moisture, assay and analysis would be entered by the chief assayer and then passed on to the office for comparison or settlement. When finished with it, it can be filed away in numerical order, thus making a convenient reference. In addition to turning in the daily statement similar to Fig. 1, and filling in the portion necessary on Fig. 2, the sampling foreman would also be called upon to make out a Daily Operating sheet. This would show the tons of ore, limestone, and ironstone sampled; tons of ore and matte crushed, quantity of ore, etc., delivered to the beds, as well as the number of men employed, and where. A form suitable for the purpose is shown in Fig. 3.

Yard Report.—This is for the purpose of giving the metallurgist a comprehensive idea of what material is in the yard and at call; it is no inconsiderable aid in the work of unloading. With this report before him the metallurgist is able to give orders to unload cars containing material that is required immediately, or those that have been standing in the yard for some time, and against which demurrage will be charged if not released promptly. A form suitable for this report is shown in Fig. 4.

This report should be made twice daily at the least; the first time in the morning, to be placed before the metallurgist as soon as he appears at his office; the second one should be made out early in the afternoon, so that the unloading may proceed during the night if necessary, or in the morning when the first gang comes on shift.

These reports can be made out by one of the clerks if the traffic is not excessive, but where it is, a special man is required.

Distribution Sheet.—When lots have been settled for and released, the metallurgist can then proceed to use

Roasting Sheet.—Besides giving the sampling foreman instructions each day as to the disposal of the various lots of ore, it is necessary for the metallurgist to give the roaster foreman instructions as to the mixtures he is to roast. This would also be done in duplicate, on a form similar

them in making up his beds or mixtures for smelting. Using a form similar to Fig. 5, he should make a duplicate copy with a carbon sheet, showing the disposition to be made of each lot of ore; one copy of the form would be sent to the sampling foreman for attention; the other would be sent to the metallurgical clerk for entry on his Mixture or Bed sheets.

to Fig. 6; one copy would be sent to the roaster foreman, and the other to the metallurgical clerk for his roaster beds. The 'Remark' column is intended to call attention to anything special. It is included in most of the forms, so that shut-downs of furnaces, repairs, etc., can be noted.

Roaster Record.—It is the duty of the roaster foreman

to keep a tally of all ore and matte, etc., roasted each day, and to report on form Fig. 7, which would also show amount of fuel used, labor employed, etc., for posting to the Daily Operating Record kept in the office for use of the metallurgist and superintendent.

Briquetting Sheet.—This is somewhat similar to the Distribution and Roasting sheets, and serves but to give instructions to the briquetting foremen as to the lots, etc., he is to treat. The form may be identical with Fig. 6. Copy of this sheet is also sent to the metallurgical clerk.

Briquetting Record.—This report is made out by the briquetting foreman each day, and sent to the office for the Daily Record. A form that has been found to answer is shown in Fig. 8.

Charge and Smelting Sheet.—Everything is now in order for the metallurgist to proceed with his smelting operations. Ores have been sampled, settled for, roasted, briquetted and bedded. He makes up his charges for the day's run, and gives instructions to his blast-furnace foreman in that portion of the Charge & Smelting sheet headed 'Charges.' See Fig. 9. The blast-furnace foreman should follow such instructions implicitly, and no alterations should be made in the operations except on receipt of instructions from the metallurgist as entered on the Charge & Smelting sheet.

The particulars of the smelting operations would be filled in by one of the blast-furnace foremen, and passed on to the office, so that they could be incorporated in the Daily Operating Record.

With the delivery of the resulting base bullion from the blast-furnace to the refinery, the contents of such bullion, as determined by assay, ceases to be a charge against the Smelting department, and becomes a charge against the Refinery, though the Refinery makes a refining charge against the Smelting department for treatment. This refining charge is a matter of estimation, based on the actual cost of treating such bullion from month to month. The contents of the slag tipped over the dump are a direct loss in smelting, and should the operations for any period show a loss of metals as compared with the quantities purchased, a considerable portion may be accounted for as loss in slag. When the operations show a gain of metals the only reason to account for it is, the smelter has received metals which have not been shown on the various records of the company. The resulting matte from the blast-furnace is assayed, and is usually worked up by further roasting and smelting to a grade sufficiently high to ship, to convert to blister copper, or to use in a blue vitriol plant. All matte from the time it is tapped from the furnace must bear its proper proportion of expense. A fixed proportion of the labor of the furnacemen must be charged to it, also all crushing, roasting, and further smelting it may have to undergo. As a certain amount of crude ore is necessary to help in the reduction of matte, an amount according to the percentage of ore on the charge must be charged to Ore account, covering the cost of labor, fuel, flux, and all other charges incurred on such run. In the event of any matte being required to assist in fluxing an ore charge, the matte so used would lose its identity as matte, and any charges for labor, roasting, crushing, smelting, etc. must be a charge against Ore account. The reason for this will easily be seen when it is known that the matte from the run in which such matte has been used as a Flux is but slightly affected. It may be a little higher in grade, but such change would be very slight, and the same process of re-crushing, re-roasting, re-smelting it to a second-grade product has still to be undergone. The charges, therefore, on such matte would be to Ore, as if the lot had come by rail, and had been through the usual procedure of sampling, etc., as with sulphide lots,

The Charge & Smelting sheet is the last of the daily reports turned in by the Smelting department, and with the delivery of the base bullion to the Refinery, we take up that department's operations.

REFINERY.—Costs against the refinery would include:

1. Cost and value of all receipts.
2. Labor employed by the refinery from the time the base bullion is received from the blast-furnace until its contents have been delivered to the parting plant in the shape of doré, or to the smelting plant in the shape of by-products.
3. Tools and supplies used for handling and treating such bullion, etc., until their contents have been shipped.
4. Cost and maintenance of machinery, furnaces, etc., used by the refinery.
5. Proportion of power and lighting.
6. Proportion of miscellaneous and general items used in common by the whole of the plant.

In addition to the base bullion received from the blast-furnaces, other bullion, rich cyanide slime, and other high-grade products, which can only be treated in the refinery, may be received from outside sources. The first sheet, therefore, for the refinery foreman to make up would be his Refinery Receipts, Fig. 10. As in the case of the sampling foreman, he would keep a permanent record in book-form, a duplicate copy of which would be turned in to the office each morning. Receipts would include the base bullion received each day from the blast-furnaces.

All the sampling of Refinery Receipts, excepting the base bullion, sample of which is taken as soon as it comes from the furnaces when it is in a molten state, would be reported on the daily report of operations, and would appear as a charge against the refinery. As with the sampling foreman, the refinery foreman would fill in the name of shipper, number of bars, or bags, brands, weight, etc., on a form similar to Fig. 2, which is to be sent to the laboratory for the assay of the consignment to be added, and then passed on to the office for comparison or settlement.

The refinery foreman's next daily report is shown in Fig. 11, which embraces the refinery operations during the day, showing ounces of doré produced, resulting by-products sent to the blast-furnaces and elsewhere for treatment.

As with the base bullion, which, after delivery to the refinery ceases to be a charge against the Smelting department, so the contents of the doré bullion sent to the parting plant cease to be a charge against the Refinery, and the by-products returned to the smelting department are credited to Refinery when shipped, the Refinery being debited with a treatment charge by the Smelter for treatment of the by-products, and a parting charge by the Parting plant.

MINING IN BOLIVIA.—The search for minerals in Bolivia is attracting the attention of several exploration companies, but, apart from the tin deposits, the results have been disappointing. Gold is obtained on the Rio Grande, where the natives on the beach wash the material which comes down the river. The gullies running into the Amazon valley were worked in ancient times, and in places some nuggets and water-worn gold were found. This place, however, is difficult of access, for there are no roads. Everything has to be transported by Indian carriers, who, owing to the density of the scrub, are compelled to cut their way with knives. The climate is very bad, fever and insect pests being rampant. The Corripata, another tributary, carries more or less gold, but the river is full of enormous boulders and the country is very steep. Some distance down the river the Indians are still in a savage state.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

TUNNEL AND MEANS FOR CONSTRUCTING THE SAME.—No. 832,120; Jules Breuchaud, Yonkers, New York.

A bottomless pneumatic shield provided interiorly with means whereby foundations may be constructed on or in the bed of a river from within said shield, with means for keeping said shield under water, and with means for advancing the shield horizontally as the foundations therebelow are constructed.

CRUSHING-ROLL.—No. 832,423; José P. Rodriguez, Caibarien, Cuba.

A crushing-roll having teeth formed in straight rows extending longitudinally of said roll, and having straight webs lying between said rows and extending longitudinally thereof.

ELECTRIC FURNACE.—No. 832,511; Edwin A. Storey, Newark, New Jersey.

An electric furnace comprising a furnace proper, horizontally-arranged conductors extending through opposite walls of the furnace, a resistor supported by the inner ends of said conductors, and a conductor supported by the furnace and movable in a plane at right angles to the plane of the first-mentioned conductors.

FURNACE FOR CALCINING OR BURNING BRIQUETS OF ORE.—No. 832,358. Filip J. Bergendal, Herang, Hafverosund, Sweden.

A furnace for the purpose specified, having an elongated main chamber, a combustion-chamber opening into said main chamber at its upper part, an inlet in the upper part of the main chamber for a combustible gas, means for compelling the flow of a current of combustion-air along the roof of said main chamber past said gas-inlet and to the

combustion-chamber, and means for injecting into the combustion-chamber, at an angle to the axis of the main furnace-chamber, a current of aeriform fluid for effecting the proper mixing of the combustion-air and gas.

ORE-ROASTING AND OXIDIZING APPARATUS.—No. 832,292; Fessenden C. Butterfield, Oakland, California.

The combination with a revoluble ore-roasting shell having means whereby ore may be admitted thereto, of a combustion-chamber separate from the shell and movable toward and from the inlet end thereof said chamber having an opening in one end for the admission of a gaseous fluid and having an air-supply pipe fixed to and movable in unison with it.

WELL-DRILLING MACHINE.—No. 832,362; Ernest O. Boaz and John Kenehan, Fort Worth, Texas.

In a well-drilling machine provided with a drill, a cable attached to said drill, a spool for said cable, and means for paying out the cable from said spool; a drill-wheel carrying a sheave-wheel for engaging said cable to regulate the stroke of the drill, a ratchet-wheel for driving said drill-wheel, means for intermittently locking said drill-wheel and ratchet-wheel together for drilling purposes, and means for permanently locking said drill-wheel and said ratchet-wheel together.

COAL-DRILL ATTACHMENT.—No. 832,096; James T. Tabor, Athens, Illinois.

A tubular coupling of the class described, having an external spiral feed-thread extending from end to end thereof, and further provided at its inner end with a longitudinal T-shaped socket and a recess intersecting said socket, a latch pivotally mounted in said recess and having a beveled engaging edge, and a spring to normally close said latch, in combination with a bit at the outer end of the coupling and having a stem in the bore thereof, and a feed-bar having a tongue at its outer end in the longitudinal portion of the T-shaped socket of the coupling and provided with an opening engaged by the latch, and shoulders at the opposite sides of the inner end of the tongue, engaging the widened portion of said T-shaped socket.

PROCESS OF SEPARATING METALS FROM THEIR ORES.—No. 832,563; George H. Waterbury, Denver, Colorado.

The herein-described leaching process consisting in placing suitably-pulverized ore in a tank containing a solution composed of water, common salt, alkali-metal nitrate and sulphurous acid, and subjecting the pulp thus formed to the action of air and steam simultaneously introduced.

Rivet Forges of Large Capacity.

The efficiency and consequent convenience of rivet-heating forges depends largely upon their capacity, ease of operation, and portability. The depth of fire must be sufficient to keep the rivets hot for several minutes should the blast be stopped, and the diameter of the bed of hot coals should be sufficient to enable more than one gang to be supplied with rivets, so that the forge may be used for general repair work of a heavier nature. The forge shown in the illustration weighs but 135 lb., and as the parts are readily detachable, being arranged so that they can be assembled in a few minutes, it is admirably adopted for use on tanks, stand-pipes, steel buildings, bridges, and in mines.

The Buffalo Forge Co., of Buffalo, N. Y., has styled this the 625 Series, which comprises three forges No. 625, 625A, and 625B. All of these measure in extreme height 44 in. and are supplied with a fan of 12 in. diam. The fan is

A Rivet Forge.

operated by helical and spur cut gears running in an oil bath, enclosed in a dust- and air-tight case, though the case may be removed from around the mechanism without disturbing the gears, as their bearings are in a frame entirely independent of the oil-case. This design insures perfect alignment and operation of the gears at all times. In this machine no spiral gears are used, as experiment has proved that they do not wear satisfactorily in service of this kind, though their use would reduce the cost. The pinion on the fan-shaft is helical, cut as is the gear driving it, which insures smooth running at all times, because always three of the gear teeth are in mesh at one time.

The tuyere is placed in the bottom of the fire-fan, which is 4 in. deep. The tuyere is in the shape of a ball, enabling the blast to be thrown in any direction to maintain a large or small fire as desired for the work in hand. Should clinker form at this point, a twist of the handle breaks it off and it drops against the clinker gate, whence it may be removed at any time. The fan-wheel is the result of several tests to determine the proper width and slope of tips relative to the cross-section of the casing, and new dimensions have been decided upon which are backed by a substantial guarantee from the manufacturer, the Buffalo Forge Company.

Books Received.

THE MINERAL INDUSTRY during 1905. Vol. XIV. Edited by W. R. Ingalls. *The Engineering & Mining Journal*. This valuable statistical book is welcomed each year by all who are engaged in mining and metallurgy, and their allied industries. This year it contains 730 pages, and is as generous with information as it is rich in statistical data. Another feature of prime importance is the greater promptitude of publication, on which the editor is to be congratulated. The principal reviews come from the experienced pens of W. R. Ingalls, Frederick Hobart, E. K. Judd, Robert H. Richards, H. O. Hofman, and F. W. Parsons. Other important articles have been prepared by specialists recognized as authoritative. In every respect this volume is worthy of the standard established by the

first editor and originator of the series—R. P. Rothwell. Vol. XIV is distinctly superior to its immediate predecessors. It forms a compendium of information absolutely necessary to those who are actively engaged in mining and metallurgy, and it will be a valuable addition to any reference library. It is for sale by the publishers at New York, and by the MINING AND SCIENTIFIC PRESS, at \$5.

The second edition of *Electricity as Applied to Mining* will be welcomed by those operating with electric power. This book, which so clearly deals with the fundamentals and also gives valuable data as to the cost of the operation and maintenance of electric mining machinery, is from the pen of specialists in mining and electrical engineering, whose joint authorship adds greatly to the value of the book. The whole volume, and especially those chapters in which transmission of power, haulage, and pumping are described, will be found to be full of interesting facts and figures.

The Principles and Practice of Surveying, by Charles B. Breed and George L. Hosmer, Instructors in Civil Engineering, Massachusetts Institute of Technology. Published by John Wiley & Sons, New York. This octavo volume of 526 pages is a textbook on surveying, which includes not only a practical knowledge of the subject, but is also adapted for teaching purposes. The most common mistakes occurring in field-work are emphasized, and every effort is made to afford right methods even in minor details. For this purpose a large number of examples from actual practice are introduced, aided by 192 diagrams. The chapter on mine surveying is by Blamey Stevens, an experienced engineer, now resident in Alaska. The book ought to prove of great usefulness. It costs \$3, and is for sale by the MINING AND SCIENTIFIC PRESS.

Commercial Paragraphs.

THE CHICAGO HOUSE WRECKING Co. has just issued Catalogue No. 145. This is the leading establishment of its kind in the world and has accomplished some gigantic operations.

L. F. BEERS has taken charge of the Detroit office of the Buffalo Forge Co., succeeding H. M. Brightman, who is now connected with the Terry Engineering & Construction Co., of Grand Rapids, Michigan.

ROBERT W. HUNT & Co., ENGINEERS, The Rookery, Chicago, have been appointed consulting, designing, and constructing engineers for the new municipal electric lighting plant for the city of Milwaukee, by Mr. Chas. J. Poetsch, City Engineer. This appointment has been unanimously confirmed by the City Council, the site for the plant has been purchased, and work will immediately start upon plans and specifications, the estimated cost being \$700,000.

THE HENDRIE & BOLTHOFF MFG. & SUPPLY Co. has just closed contracts for the exclusive sales agency of the King screen. This screen is the invention of Howard G. King, formerly superintendent of the Colorado Zinc Works, at Denver, and one of the best known millmen in the State. The screen has been in practical use for about a year, and has proved such a success that Mr. King has resigned his position at the zinc plant and will hereafter devote his time to the manufacture of this screen. Circulars and printed matter will shortly be ready for distribution. The screens are on exhibition at the main office of the Hendrie & Bolthoff Company.

THE CHICAGO PNEUMATIC TOOL Co. reports that up to Oct. 25 orders booked had exceeded orders for first 25 days of October, 1905, 40% and an increase over September of 37%. The amount of business done for the first nine months of the current year has shown an increase of 27% over corresponding period in 1905. Notwithstanding the fact that the Chicago Pneumatic Tool Co. had on their books at the close of the year 1905 an excess of 8,000 active customers, they have added to this large list during the first nine months of the current year over 1,500 more customers, which indicates clearly the rapidly increasing popularity of the company's product and the extent to which they have been able to broaden the field for their tools and appliances generally.

Editorial.

THE CALIFORNIA MINERS' ASSOCIATION will meet in annual convention in San Francisco on December 3. The session will last four days. It is intended to enlarge the scope of the association and make it thoroughly representative of the mining industry in California.

THE FIRST SHIPMENT of zinc ore from Washoe county, Nevada, was made recently to the smelter at Iola, Kansas. Antimony ore of good grade, and free from arsenic and lead, is being mined near Mill City, in Humboldt county. Nickel, as is well known, is produced at Lovelocks, also in Humboldt. These facts are suggestive of the variety of mineral resources possessed by a State that until recently was supposed to produce silver alone, and is now the scene of the greatest excitement in gold mining.

LEAD ORES are becoming scarce in Colorado and Utah. Leadville now yields an excess of pyritic material and only a small proportion of lead, mainly carbonate ore from the gleaning of the old workings. In Utah the lead used to come from Bingham, Park City, Stockton, and Little Cottonwood. Bingham is now a great copper district, and one almost forgets that it once supplied a large tonnage of lead ore. The Yosemite was especially productive in this respect, for it was of the lead sulphate which came from this mine that George Hearst said: "You could melt it in a frying pan." As a collector of the precious metals in smelting, copper has replaced lead.

THE COPPER MARKET continues strong and healthy. Consumption in the United States is fully up to the production of the metal. Scarcity of labor is curtailing the output of many mines. The shipments from Chile are less than last year, and the visible supply in England is considerably less than twelve months ago. Spain and Australia have increased their exports, so also has Japan. But the Japanese production is small, while domestic consumption there is increasing rapidly. The directors of the Rio Tinto Company stated recently that the indications point to a continuance of high prices in the copper market, and that consumption all over the world is increasing at an even more rapid rate than the output. This appears to be justified.

A MINE PROMOTER named Whalen was convicted this week in California of salting a mine in Nevada. He was sentenced to ten years. The Judge said: "This thing must stop. It is worse than highway robbery. I have more respect for a highway robber than for a man who goes about with an air of respectability swindling poor people." It is time the community in general shared the Judge's opinion. The transfer of cash from one person to another by means of plausible mis-statements is considered clever by many people who regard a

hold-up at night as a disgraceful occurrence. The daily press is full of invitations to buy stock in prospects that are described as producing mines. Several of our local newspapers continue to publish the offer of shares in the invention of a man who has a cold-storage motor that will do impossible things and who undertakes to make poor people rich, that is, to take from them the small earnings of a lifetime in return for worthless paper. The publishers of these papers know that it is disguised robbery, and yet they do not hesitate to accept the advertisement, because they are paid for it. For these men, also, we have no more respect than for highway robbers.

Railroad Building in Nevada.

Nevada evidently is destined to be well served by railroads. Soon there will be a through service of trains from Las Vegas on the Los Angeles & Salt Lake railroad, in the southwest corner of the State, to the Southern Pacific, both at Reno and at Hazen. Last month the new railroad from Cobre, on the Southern Pacific, was opened southward to Ely and now we hear that another branch line is to be built from Tintic Junction in Utah to Deep Creek in western Utah, which will help those who want to prospect in eastern Nevada. It is probable that a short length of railway will soon connect Pioche to Caliente, on the Los Angeles & Salt Lake line. Finally, we have good authority for the belief that a railroad will be laid down between Ely and Goldfield, across the very heart of the gold regions of the desert. What we need next is a direct outlet to the Coast, more particularly San Francisco. It is rumored that W. A. Clark has purchased the control of the Ventura & Bakersfield Railroad, known as the Burson line, and that he will extend it to the Coast. This road seems to be too far south to be of any advantage to San Francisco, and as we are to have important copper and lead smelters on the Bay, it appears likely that more direct communication will be secured with the new goldfields, through the Sierras, somewhere in the northern part of Inyo county, California, and across the boundary into Nye county, Nevada. The silicious gold ores of western Nevada and the pyritic copper of Shasta county, California, must be smelted on the Bay of San Francisco.

Gratuitous Advice.

Most mining engineers give a great deal of valuable advice for nothing. They cannot help it. Their friends and acquaintances think it proper to take up their time and to get useful hints on mining shares and on technical matters, without any question of payment for services rendered. Doctors and lawyers are not imposed upon in this way; their professional status is honored, the trespass on their time is properly debited in fees, however small. Any mining engineer, geologist, or metallurgist living in a large city and possessed of an average acquaintance will donate thousands of dollars' worth of advice per annum to those who thus impose on his good nature. It is time to stop the practice. Let professional men adopt the idea of making a small charge—\$5, \$10,

or \$25, as the case may be—for all replies to questions bearing upon mining speculation, management, machinery, processes, and other subjects of commercial importance. If adopted, such a method would save the engineer from the importunity of those who are not serious or who are mean, while it would encourage many men to get advice who now feel that they must either engage an engineer at a big fee or be guilty of an imposition by asking something for nothing. We have spoken of this matter before, and we are prompted to refer to it on this occasion by reason of the receipt of a circular letter from a reputable—almost celebrated—mining engineer at London, who offers to give five replies concerning the merits of mining ventures for two guineas, and will give an unlimited number of replies for five guineas. To the letter is attached a form of subscription, covering the proposal described. He is simply asking pay for doing what he and others have all along been expected to do for nothing.

Mining in Korea.

All of those who have any knowledge of political conditions in Korea, will not be surprised to learn that the new Mining Laws discourage the investment of foreign capital. The policy of the Japanese has been pretty frank from the beginning, namely, to exploit Korea for themselves. By the courtesy of the editor of *The Korea Daily News* we have been enabled to read the mining regulations recently issued and the reading of them sustains his conclusion that unless they were drafted by a humorist, their intent is to prohibit foreign investment in Korean mining enterprises. Article No. 10 provides that no mining right may be sold, assigned, or mortgaged without the consent of the Korean Minister for Agriculture. Article No. 21 states that the Korean Government will not be responsible for the actions of this Minister; while Article No. 27 stipulates that the Minister may make no transactions with foreigners without the consent of the Residency General. As the Residency General represents Japan, while at the same time the Japanese Government has declined to make itself responsible for acts against foreigners committed by the Residency General, there is a game of hide-and-seek which serious investors will not find amusing. In the meanwhile the administration of mining is placed under the Korean Minister of Agriculture, and that eminent farmer will be the scapegoat in case of dispute, while at the same time serving as a convenient tool in the hands of the Japanese, if there be any who wish to exploit the mineral resources of Korea. As the Japanese have but little capital available for outside enterprise, it is not likely that Korea will be developed with any notable rapidity.

Nor need we be anxious about it, for there are ample opportunities for the use of money in mining regions much nearer home. At the present time the Western States of America afford a splendid field for capital from both sides of the Atlantic. There is a proverb that says the oxen farthest from home have the biggest horns. Distant mining districts often cast a glamor that is deceptive. Mining, like charity, should begin at home.

By the Way.

At a recent meeting of the Schenectady branch of the American Institute of Electrical Engineers, an address was delivered by Mr. T. Commerford Martin, editor of the *Electrical World*. He said, in part:

It sounds almost heretical to express the idea that a modern man can live without a daily newspaper, but Lord Kelvin once allowed to me that he virtually did so without cheating his brain. The placard bulletin, the megaphone, the ticker tape, and the sky signal-lights could keep one fairly *au courant* with all the news of plague, famine, and sudden death that is necessary to happiness. But it is hard to conceive how a man desirous of keeping abreast of invention, improvement, experience, and discussion in his profession or industry can possibly do so if he does not read with at least moderate diligence his technical paper. Even the worst trade journal is better than none; and the best will leave a true hunger for knowledge sorely unsatisfied. The technical journalist is a specialist, he is cultivating a restricted territory, he is working with a microscope, all of which tells against largeness, broadness, liberality. Yet, intensified cultivation has its merits, and many a patch of lilies in Bermuda, or vines in France, yields a far more valuable product than a sprawling wheat farm in Minnesota with its thin 15 bushels per acre.

No technical man can find outside his special class journal the right intellectual food—tough, indigestible, and badly cooked as most of it may be. The efforts of the daily press to be technical and supply valuable data, are laudable; the engineering supplement to the London *Times* is the best example of how far such a tendency can go; and the synopses given in many American journals of scientific and industrial news are praiseworthy from the standpoint of the average reader. But much of what gets into print thus is to be regarded with suspicion, though reflecting no discredit on the daily whose pages it brightens. Now and again there is a book in the nature of a revelation, but the majority of the text-books, in our schools and on our shelves, are years behind the latest things going. These facts the student, in college or out, must get from the technical press. Being often asked for the latest book on a subject I have been struck with the frequency, the invariability with which one's recommendation unavoidably carries with it a number of articles recently printed in the technical press.

When I meet a young engineer and discover that he has, unless for some valid reason, failed to join the national or local society of his branch of engineering, I find myself involuntarily putting a black mark against his name. When I discover also that he does not read regularly the journals of the art, he becomes more hopelessly 'conditioned' in my mind, as one without professional pride and dignity, and as one who on his own confession does not keep himself so informed about progress that he can be properly useful in the world.

I have been formulating a plea or reason for the existence of technical journals as the clearing houses of current knowledge, as a necessary tool, as a means of intercourse, without any implication that any one of them is all that might be expected of it. Every human institution is branded with imperfection, and it is only of late years that most technical journals have even begun to attack the tasks before them or discharge the responsibilities resting upon them. Aside from the conceded inadequacy of the editors and managers—nowhere more painfully realized than among themselves—two very great difficulties steadily prevent these luminaries from being of full candle-power. One of these is the inability

to find men who have a story to tell and who can tell it well. The other is the reluctance of corporations and individuals to make public for common benefit the information acquired primarily for themselves in dealing with a subject, and often at enormous expense. Both these are evils and may be glanced at separately.

It may appear curious in these days when it is supposed that everybody writes to complain that there is not writing enough. Lady Holland once said to Lord Porchester: "I am sorry to hear you are going to publish a poem. Can't you suppress it?" And when one wades through the countless popular magazines, and the endless Sunday newspapers, and realizes how many beautiful miles of the forest fall daily under the axe to supply food for the ravenous presses of the age, it does seem as though the whispering trees would be better than so much loud talk. But as sinners against the Adirondacks, the technical papers are venial offenders with their little editions, when compared with 'yellows' boasting half a million copies daily, or 'muckrakers' running a million per month. Those outlets for the productions of the intellect are always clogged with copy, but the technical journals in reality have little offered them voluntarily, and are frequently at a loss to get the right man to deal with a topic. For some inexplicable reason, the phrase 'an officer and a gentleman' does not find its equivalent in 'an engineer and an author,' although the engineer almost daily has an experience or an observation which, if duly recorded, would be of value and economy to every one else in the same field of work; and even if the single fact is of little utility, a number of them might permit the generalization out of which great truths and great inventions would presently emerge.

If the technical journals could get more of these articles, they would pass in glad silence over the fact that the authors knew little of prosody or syntax, and have never used any but 'simplified spelling.' The great want of the time is, indeed, the ability to observe and then tell clearly and directly what is seen. This whole great electrical field of ours teems with obscure phenomena, with hints, suggestions, ideas, so that if a man notes something and does not know himself how to make use of it he can at least be useful by passing it on. There may be an improvement or a refinement in the art involved in the merest trifle; there may be the germ of a great invention. Chiefly thus does the improbable or the impossible become the prosaic and commonplace. "Numerous attempts have been made," said Herbert Spencer in his treatise on Education, "to construct electro-magnetic engines, in the hope of superseding steam, but had those who supplied the money understood the general law of the correlation and the equivalence of forces, they might have had better balances at their banks." These very works are building yearly thousands of dynamo-electric machines that supersede steam in every branch of industry, but the process of their creation since Spencer wrote, down to the moment when No. 6,000 went on the Central tracks, has been one of almost imperceptible gradations of advance; and each advance has involved one closer observation of the conditions and facts to be dealt with in solving the problem. Such data are the very pith and marrow of the technical journal, and while I yield to none in profound admiration of the creative inventor—Edison, Thomson, Rice, or Steinmetz—I become more and more convinced that in large measure the magnificent growth during the past century in the arts and sciences is due to the swift printing and circulating of new knowledge, which even to the genius is stimulating food for thought. In other words, the technical journal is an essential tool of professional, industrial, and commercial life.

Special Correspondence.

London.

Cornish Mining News.—High Bank Rate Does Not Stop Speculation.

—General Activity in Mines.—Zinc Corporation Increases Its Capital.—Reports from Esperanza.—Farish's Report on Dolores.

—Good Work at the Camp Bird.

A large attendance of smelter and mine representatives is reported at the Cornish 'ticketing' last week. The average price per ton of black tin went to £113.17.0, and the quality showed an improvement—total, 242½ tons—realizing £27,608.

For the four weeks to October 20, Dolcoath crushed 7,876 tons and sold 130 tons of black tin which averaged £120.18.9 per ton. At East Pool, the water difficulty is reported as practically solved, so that the bottom can now be examined. It is generally thought that the prospect justifies the vigorous development of this part of the mine, as the lodes which gave such large profits in the upper levels are converging and should form a junction a few fathoms deeper. The broken pumping engine at Carn Brea has been repaired, but there does not appear as yet to be much improvement in the mine, although the working operations are now yielding a profit. Efforts are being made at Wheal Vor to commence drainage operations. The water in the mine is not very heavy, so that returns are hoped for early in the coming year. One of the next flotations, it is said, will be North and South Tolcarn, Camborne, as a united concern under the limited liability system. The transfer of the setts has been made, the vendors being W. J. Gilbert, James Rowe, Peter Temby, and W. H. Odgers, of Camborne. The property lies on the west of Grenville United and Great Condurrow mines, and contains eight proved tin and copper lodes. Capt. Gilbert thinks that the mine will be in full swing by the early part of 1907.

The high bank rate, while disconcerting to holders of gilt-edged securities and small speculators, has had little effect on certain specialties of the mining market. Among these, Siberian ventures have held their own, but it is recognized that these dealings are mainly of the 'shop' description, the interest of the public not being aroused even by sensational fluctuations, such as have occurred the last few days in New Vaal River diamonds or in a lesser degree by the upward movements in Cobalt Townsite, Broken Hill descriptions, and the Australian deep leads. The rise to £12 in New Vaal Rivers (£1 shares) is said to be due not merely to the discoveries at the mine, but also, if not mainly, to the squeezing of a ponderous 'bear.' On the other hand, "dear money" does not seem to have had an appreciable effect on the work of financial groups in opening up new fields of enterprise, and enlarging others already in operation. According to a telegram from Ekaterinburg, an English capitalist has acquired numerous gold mines in that district. The sum mentioned is 5,000,000 roubles. It is stated that 6,000,000 roubles will be spent in the development of the properties. The same capitalist, it is added, has also bought various properties and copper mines in Siberia and the Caucasus.

Coming nearer home, the directors of the Zinc Corporation have decided to recommend to the shareholders that the capital of the company be increased to £500,000 by the creation of 150,000 new shares ranking in all respects equally with the existing shares. Of these shares it is proposed to issue 113,333 at 25s., and to give all shareholders the right to subscribe in the ratio of one new share to three old ones. The board has arranged for a guarantee of the 113,333 shares at the issue price, with-

out any consideration beyond the option to subscribe at £2 per share for the remaining shares, namely, 46,667. This guarantee has been given by Messrs. E. L. & C. Baillieu, of Melbourne, Messrs. Bewick, Moreing & Co., Messrs. Govett, Sons & Co., Messrs. Lionel Robinson, Clark & Co., and the London & Western Australian Exploration Co., Ltd. This issue will provide the company with £141,666 additional cash, and, if the option be exercised, with a further sum of £93,334, available for the following purposes: (1) To provide money for the exercise of further options over the tailing already accumulated and that to come from current operations of the mining companies under contract. (2) The expansion of the No. 2 plant on the British Broken Hill Proprietary to a capacity of 12,000 tons per month. It is anticipated that this plant will be in operation by the end of the year. (3) The completion of the No. 1 plant in course of construction at the company's site on the Broken Hill South Blocks mine, which is expected to be in operation by March, 1907, and of a capacity at first of 15,000 tons per month, but with the main portion of the structure providing for an expansion to 30,000 tons per month. (4) For the construction of a smelting works.

The quarterly report of Esperanza (Mexico) to the end of September shows an estimated profit for the period of \$1,370,495 from 41,606 tons of dry ore crushed and 21,784 tons shipped to smelter. Mine development, 3,109 ft. According to extracts given from the manager's reports it appears that on the sixth level, south section, the north drift at raise No. 13 was advanced along the West vein 123 ft., showing a width of four feet of high-grade ore, and that the south drift at raise No. 13 West vein, was advanced 100 ft., also in high-grade ore. In the north section, on the seventh level cross-cut No. 24 west, north drift, east cross-cut is reported as having passed through a vein about six feet wide, composed of quartz and slate mixed. Assays obtained were high, averaging 1 oz. 15 dwt. gold per ton. At various other points in the mine the workings are described as being in "good" or "fair" milling ore. In spite of these satisfactory reports, huge monthly profits and the directors' denial of adverse rumors only a month ago, the price of the shares has been persistently lowered on the Stock Exchange. At the present figure (2½ to ¼) it appears to have reached about a parity with the cash in hand added to the value of the ore actually blocked out. The weakening of Dolores on the market is explained by the forthcoming issue of 66,000 new shares at the price of \$5. The very full and comprehensive report of Mr. John B. Farish on his first visit to the property in June and July, although in no sense disappointing, as to his opinion of the mine, seems rather to over-emphasize its isolated position and the difficulties of labor and transportation. These no doubt require special handling, but should not call for more than an ordinary measure of ingenuity, foresight, and resource on the part of the management. Mr. Farish recommends a further expenditure on Capital Account of about \$80,000 "in order to make the population of Dolores comfortable and contented, to increase our milling capacity to a maximum of between 1,500 and 1,600 tons of ore per month, and to ensure prompt movement of freight between the railroad and the mine." Referring to the immediate outlook, Mr. Farish quotes from the manager, Mr. J. Gordon Hardy, who says: "The production, while not yet up to its maximum, should speedily get there and swell our present profits of \$20,000 per month. Developments in the mine with depth, on our known orebody, are exceedingly encouraging, and are reaching the stage where it will be possible to place in sight additional reserves of magnitude." —A smart piece of work has been accomplished at Camp Bird, in replacing the mill destroyed by fire after the

snowslide in March last. It is reported that 20 stamps were started on October 29 and that the full mill would be running November 1, that is to say, a month earlier than anticipated.

Melbourne, Australia.

The Zinc Corporation Affairs.—Economical Tin Mining in Tasmania.—
Copper Mining in Queensland.—A Pamphlet on Cloncurry.—
Newcastle Strike Ends.—Better Outlook at Broken Hill.

Affairs have undergone several changes in connection with the Zinc Corporation. The most important is the retirement of Herbert J. Daly from the position of managing director. The cause of this is not far to seek. Messrs. Bewick, Moreing & Co., and those associated with them in London, naturally, when they own the bulk of the shares in a company, like to dominate it. Therefore, despite the existence of a contract for the retention of the services of Mr. Daly by the company for a term of years, he has retired. Before this took place, however, a straight-out offer was made for Mr. Daly's interest in

the venture. He accepted the offer and then could not refuse the wish of the London holders to control the management. Later on, Mr. E. S. Simpson, who was brought over from Western Australia to direct operations for the company at Broken Hill, tendered his resignation, and Mr. Bradford, the chemist who was taken from the Broken Hill Proprietary Co. to supervise the treatment experiments, is resigning. The Broken Hill Co., once they heard of his resignation, snapped him up so as to secure the services of the man who knows as much about the treatment of the zinc-bearing ores of Broken Hill as anyone in Australia. Mr. Huntley, of the South Blocks mine, is to succeed Mr. Simpson. Mr. A. L. Queneau continues as consulting engineer. Mr. Queneau has been traveling between Broken Hill and the south coast of New South Wales to decide as to whether zinc smelters shall be erected by the Smelting Corporation at Kembla. So far, however, the public have not been let behind the scenes. This is a thing that Australians do not like, for one of the cardinal principles of their company laws is that the shareholder, as a partner, has a right of access to documents. Some day this point will be fought out in deadly earnest by an indignant shareholder who has suffered from lack of knowledge.

The Anchor tin mine in the Blue Tor, Tasmania, holds a record (in Australia, certainly), for cheap work. It

treats a porphyritic rock carrying tin. The company is English, and its affairs were for a while administered by Mr. Lindesay Clark, who is now general manager of the Briseis tin mines, at Derby, also a big English concern. The present manager of the Anchor, Mr. J. B. Lewis, is a good successor to so able a man as Mr. Clark. The company has 100 stamps, and it has to treat ore carrying tin to the value of only 4s. 6d. per ton. Power is derived from Pelton wheels driven by water brought down from the adjoining ranges. Mining is all open-cast work, the ore being first treated in rock-breakers that deliver it automatically into trucks to be crushed at the battery, the tin oxide being subsequently saved on vanners and buddles. The working costs are only 2s. 6d. per ton and the receipts 3s. 6d. per ton, so that the best work has to be done to ensure profits. Last quarter the company treated 38,878 tons for 61½ tons of tin oxide. The duty per stamp was about six tons. In addition, sluicing is done on a flat containing tin-bearing gravel, the returns being about 7d. per cu. yd., and the costs 3½d. This is about the average of the Briseis. With such poor ore as the company has to rely on, it is an everlasting tussle to keep on the right side of the ledger. But the task is achieved and the amount to credit is being quietly increased.

A very bitter pamphlet on the leading 'Copper Properties at Cloncurry, North Queensland,' by W. P. Rutherford, Jr., of the Tharsis Copper Co., and Mr. Kitchener, brother of Lord Kitchener, has been issued by the first-named. The district is receiving close attention just now because of the resurrection of a number of old mines under the shelter of the high copper market. The Cloncurry district has been dormant for many years, owing to the low price of the metal, the difficulty of access, the bad climate, and lastly the want of timber and water. The collapse of the Chillagoe boom has made the public very cautious about North Queensland, and this pamphlet will not help the market. Mr. Kitchener contends that the deposits of ore exist (1) as impregnations usually in the form of green carbonate, the copper having been laid down at the same time as the sandstones, and (upon their being tilted) having been leached out and re-deposited along lines of stratification usually near beds of quartzite, or (2) as small lenticular deposits in the folds, or along the bedding planes of schist and shale. He says that all the rich ore has come from these pockets, and in no case has he seen "a true or fissure lode, and nowhere does the ore occur between well-defined walls." The sting of the pamphlet is that it is, in the main, the report that was sent to the Tharsis Co. (London) when in its search for a new property it had the Cloncurry district investigated by Mr. Rutherford. All the same, the reports to hand from the field respecting the Mt. Elliott mine, a claim in which a good deal of English money is being sunk, is satisfactory so far as work has gone. In that case the depth reached is only a little over 100 ft. The test will be when the water-level is reached. This has been the case with all the mines in the district, and it may be as well, therefore, that Mr. Rutherford has issued this note of warning.

The most pleasant piece of news in respect of mining is that all fear of a strike at Newcastle is at an end. This happy issue was the result of a prolonged conference between the miners and the employers. Both sides did the usual bluffing, but the fact that the owners were making such good profits and did not want to interfere with the splendid trade now being done in coal, was a factor in making them somewhat more plastic than usual. The fight over the retention of the 'dog' watch, or third shift, has resulted in the directors deciding to cease the practice. Everyone gave a sigh of relief when it became known that the parties had come to an agreement. The

selling price of coal will be raised to 10s. per ton on January 1 next, and the miners then will receive an increase of 4d. per ton on the hewing rate. At Broken Hill also the atmosphere was cleared, as the miners' request for an increase in wages, owing to the great profits being made by the company, is likely to receive favorable consideration. Mr. Delprat, speaking on behalf of the Mine Managers' Association, having declared that it was only fair that the workers should share in the prosperity of the company. A conference between the Miners' Union and the Managers' is to take place at an early date.

Johannesburg, Transvaal.

Diamond Flotations in South Africa.—Base-Metal Mining.—The Railroad Into Northern Rhodesia.—Scarcity of Capital for the Rand.—Complex Political Conditions.

Diamond flotations are very popular on the Rand at the present time. The number of syndicates that are being formed and the new companies floated prove how popular this form of gambling has become. Out of the long list one or two properties stand out as mines that will be successful. One new company had its first run the other day, and got a return of 0.666 carats per load. This is a good beginning. Most of the new diamond mines are in the Orange River colony, for the diamond law in that part of South Africa is far more favorable than in the Transvaal. If all these companies succeed in finding diamonds, one wonders what the effect on the market will be. So far the price has kept up remarkably well, in spite of the huge output of the Premier Diamond Co. Some people feared at one time that there might arise a serious competition between De Beers Consolidated and the great Transvaal producer, but so far the market has remained healthy. The diamond trade is watched by some of the cleverest men in the world, and there is no doubt that they will not allow the market to be swamped, no matter how many diamonds are turned out. To make diamonds as cheap as marbles would mean ruin to all concerned.

Tin and other base metals are in the background just now. Since the collapse of 'Sallies,' the public seem to be averse to base metals, especially tin. Great efforts are being made to get successful copper propositions in the Transvaal. Any number of prospects have been met, but so far the results appear disappointing. The prospects seem to be of the will-o'-the-wisp order. Beautiful samples are brought in, but upon investigation the mine is found to consist of a few specimens. Edendale Estates, a lead proposition, is opening up quite well, and it looks as if this would turn into a payable base-metal mine. On account of the hard times, it is impossible to do much with the mine at present. The owners are developing it slowly, and are waiting for better times.

An event of great interest to South Africa is advertised for next week, and that is the opening of the railroad from Victoria Falls to the Rhodesia Broken Hill mine, 400 miles north. This will be a great day for Central Africa. So far Rhodesia has been a country of bitter disappointments, but it is stated that when the Broken Hill mine commences sending lead and zinc ore to Europe, people will realize the immense possibilities of this region as a base-metal producer. There is a scheme on foot to amalgamate northeastern and northwestern Rhodesia into one government, and to move the capital from Kalomo to the environs of Rhodesia Broken Hill. The immediate neighborhood of the mine is flat, rather unhealthy country, but six or seven miles away there are some high hills, which would prove an excellent site for the new capital. Thus by mining is civiliza-

tion being carried into the very heart of the Dark Continent.

The Transvaal is beginning to feel the scarcity of capital. It would be almost impossible to float a 'deep level' at the present time. Several deep-level mines have ceased operations and will wait for better times. A number of shafts are being pushed ahead on the central Rand, the most important of which is the huge seven-compartment shaft of the Turf mines, which does not expect to strike the reef at much less than 4,000 ft. Only one shaft is being sunk on this property, as it is expected to connect with mines to the north for ventilation.

Politics are playing the most important part in the Transvaal at the present time. New parties seem to be born every day. The British population seems to be more disunited than ever. The Boers have only one party, 'Het Volk.' They are not saying much, 'just sawing wood.' The uncertainty of the future is positively disconcerting. All sensible people realize how easily the noble fabric of the mining industry can be disabled or wrecked. At present there is much distress. If you are an American citizen you get many requests for assistance from people hailing from the same country.

Butte, Montana.

The Boston & Montana Sinking on the Badger State.—Resumption of Work on Several Large Mines.—Great Activity in Developing the District.—The Goldsmith Co.—East Butte Explorations.—Butte & London.—The Amazon-Butte Erects a New Plant.

The Boston & Montana Co. has begun sinking a shaft on the Badger State claim, situated east of the North Butte mine, and will probably sink to a depth of 1,500 ft. The rich vein of the Jessie, owned by the North Butte, is known to strike through the Badger State, and when opened that property is expected to prove one of the most valuable in the possession of the Boston & Montana. The company will be able to work not only the Badger State through the new shaft but also the Auraria and Moose and several other claims in that neighborhood. The Boston & Montana ground is practically in the centre of the North Butte section.

All of the large copper mines of the Butte district are again in operation, the last one to resume is the Never Sweat of the Anaconda. The latter was closed for several weeks on account of the shifting ground under the hoisting engine. It has been repaired and the engine is again running smoothly, but it is the opinion among mining men that it will be but a question of time until the engine will have to be moved to firmer ground. The closing of the Never Sweat shaft did not make much difference in the output of the Anaconda mines, for the property was mined just the same and the ore hoisted through adjoining mines. The Colusa, of the Boston & Montana, has also resumed work and now all the mines of the Amalgamated are producing again, the total output of the Amalgamated properties now being about 10,000 tons per day. The total daily output for the district is in excess of 13,000 tons.—A great amount of development work is going on in this district, and a large amount of new territory will be open for mining during 1907. Sinking is being done on the Parrot, Pennsylvania, West Colusa, Cora, North Butte, Badger State, Granite Mountain, Leonard, Blackrock, Elm Orlu, Colusa-Leonard, on three claims of the Butte & Bacorn, on the Trifle of the Butte Copper Co., Ida-Montana, East Butte, East Butte Extension, Ophir, South Butte, Farrell & Alliance, Greenleaf, Pittsburgh & Montana, Davis-Daly on four shafts, the Tuolumne, Anaconda, and on a number of other properties. The Davis-Daly Estates has purchased another 30-ft. frontage on Broadway adjoining the

Smokehouse shaft, corner Broadway and Wyoming streets, for mining purposes, in the very centre of the business district.

The recently organized Goldsmith Mining Co. is working 50 men and hoisting about 150 tons of ore daily; this is shipped to the smelter at East Helena. The lowest net returns from the smelter on recent shipments were \$12 per ton. The ore runs high in silver and also carries gold and copper; the lowest copper assay recently was 3½%. On the 400-ft. level the vein has an average width of three feet, with stopes 100 ft. high. At the west end of the Goldsmith there is a quantity of ore in sight that assays 160 oz. silver, \$18 in gold, and one per cent copper. The great Rainbow lode, in the northern part of the Butte district, strikes through the Goldsmith properties. It is the opinion of mining men that at greater depth than is now opened, the Rainbow lode will be found rich in copper.

The shaft of the East Butte Mining Co. has reached a depth of 600 ft., where a station is being cut. When it is finished, sinking will be resumed and continued to 1,000 ft. Work continues in the north and south cross-cuts from the 400-ft. station, but no other cross-cutting will be

Montana.

done until the big shaft being sunk at the southern extremity of the company's ground is deep enough for connections with the main shaft at 400 ft., so that the mine can be ventilated. The north cross-cut has opened the vein of the Simons mine at the 400. The vein contains 2½ ft. of copper glance, and is the same orebody that is being mined on the upper levels by lessees. The iron cap on the Glengarry vein, one of 21 veins that cross the East Butte Co.'s ground, is absent from all the other veins that have been mined. On the Glengarry the iron is encountered at a depth of 160 ft. and continues for 150 ft. deeper. The Hancock shaft of the East Butte is now in the iron zone. The J. I. C. shaft of the Anaconda Co. is also on the Glengarry vein, and although mining is being done to a depth of 400 ft. the iron has not yet been encountered, showing that the iron zone dips deeper into the earth as it goes westward. The iron cap is found in many mines of the Butte district and at varying depths.

The shaft of the Butte & London has reached a depth of 725 ft., but there is little change in the character of the ground. The 12-ft. vein that was cut two weeks ago has passed out of the shaft to the south; when a depth of 800 ft. is reached a station will be cut and a pump installed, after which sinking will be resumed and the shaft carried to a depth of 1,200 or 1,500 ft. It is not likely that any cross-cutting will be done short of the 1,200-ft. level.

The Amazon-Butte Copper Co., recently organized in

Butte, is erecting a hoisting plant and will soon be equipped to begin sinking and development. The company owns the Amazon, West Altona, and Gaynor claims, southeast of the old district of Butte, and at the junction of the Bullwhacker and Ida-Montana veins. The Bullwhacker vein strikes north and south and that of the Ida-Montana Co. east and west, and whatever there is in the Bullwhacker and Ida veins is expected to be found in the Amazon-Butte ground. All the machinery has been delivered and ground has been broken for a three-compartment shaft at a point of intersection of the east and north veins. John Hewett, formerly superintendent of the Gagnon mine of the Trenton Co., has taken charge for the Amazon-Butte. The company is well financed and the work of development will be prosecuted rapidly. A number of new companies are now operating on the east side. Among them are the Butte Copper & Exploration, Butte & London, Amazon-Butte, Boston & Montana, Bullwhacker, Ida-Montana, Lewisohn General Development, Pittsburgh & Montana, Colusa-Leonard Extension, and Calumet & Butte.

Toronto, Canada.

Transfer of Mines at Cobalt.—The Glendinning is Sold.—La Rose Prospecting With Diamond Drill.—Promising Developments.—Good News from Kerr Lake and the Nipissing.—Mining Under the Lake.—Larder Lake District.—Silver Discoveries in Temagami Region.

The principal feature in the Cobalt mining situation continues to be the heavy investments made by American capitalists in mines of established reputation, and the acquiring of controlling interests in prominent Cobalt companies by new organizations. The most important transaction of the week was the sale of a nine-tenths interest in the University of Glendinning mine to a syndicate composed of John McMartin, Duncan McMartin, David A. Dunlop, Henry Timmins, and Noah Timmins, all largely interested in other Cobalt mines. The price is understood to be about a million dollars. The property comprises 50 acres on the shore of Giroux lake and the ore in the veins so far developed is holding out at a depth of 300 ft. Machinery is being installed to develop other veins showing on the surface. The stock will shortly be placed on the market.—A controlling interest in the stock of the Gilpin Cobalt Silver Mining Co. has been bought by H. Dreany, of Toronto, on behalf of a New York and Boston syndicate; the price being upward of \$400,000. The property is in Bucke township 2½ miles west of Haileybury. Willis Abbott, of New York, has purchased for \$320,000 40 acres of mining land from the Gordon Cobalt Silver Mining Co., situated about one mile from Cobalt town. It has not yet become a shipping property, as the ore is comparatively low grade, assaying 70 to 120 oz. per ton. The Violet mine, a shipping property near Cross lake, has been bought by Clarence J. McCuaig, of Montreal. Numerous other deals of undeveloped properties are reported.

The Ontario Government has begun the publication of monthly official reports showing the shipments of Cobalt ore over the Temiskaming & Northern Ontario Railway. The shipments for the month of October amounted to 1,120 tons, the Nipissing mine heading the list.

At La Rose mine, the diamond-drill has been sent down over 200 ft. below the bottom of the 300-ft. shaft. It was in high-grade ore all the distance, the lowest point showing ore equal to that found in the surface workings. Development work is being actively pushed at the Kerr Lake, or Jacobs, mine at a depth of 130 ft. below adit-level on the main vein. The cross-cut shows high-grade ore and a banded fissure with several other

calcite streaks in addition to the 4-in. vein of high-grade ore. At the Nipissing the fault at the bottom of the south drift of vein No. 26 has been found several feet to the east, where there is a showing of 12 in. of ore, considerably richer in silver than the upper part of the vein. The shaft is going down and a station will be cut for driving both ways on the vein. Vein No. 27 broadens out at the 35-ft. level to nine inches and shows rich free-silver contents. The operating force, numbering 200, is being steadily increased. The Coleman Development Co., operating about five miles southeast of Cobalt town, has opened up a promising vein of cobalt with a fair showing of leaf silver. The Columbus is developing a vein of cobaltite, but the silver content is low. At the Big Pete location, near the Foster, a calcite vein has been struck at the 30-ft. level, which it is thought may prove to be a continuation of one of the Foster veins. The Silver Queen has opened up a new 12-in. vein which shows some native silver and promises well. At the 75-ft. level on the main shaft about 100 ft. of driving has been done. The vein of high-grade ore shows a steady width of 16 to 18 in. and the wall-rock is highly mineralized.

The Ontario Government on the 7th inst. heard applications on behalf of the representatives of the Bessey claim and the Green-Gordon claim, to be allowed to mine under the waters of Cobalt lake from shafts sunk on the shore. Premier Whitney's attitude was strongly against the applications, but the decision of the cabinet was reserved.—G. T. Smith, mining recorder at Haileybury, Ont., states that upward of 350 claims have been so far located in the Larder Lake goldfield. None of them have so far been inspected, and as the district is now practically inaccessible, owing to the setting in of winter, the inspections necessary to confirm the titles of the locators cannot possibly be made before spring. Nevertheless the formation of stock companies based on these discoveries will go merrily forward for the benefit of the small investor, who seems ready to snap at anything in the shape of a mining proposition.

Rich silver finds have been made in the southwest corner of Auld township in the Temagami forest reserve. Twelve claims have already been staked. White Brothers, of Muskoka, have taken up a location containing large quantities of native silver, specimens of which have been brought down. F. N. McConnell, of Haileybury, has also made a good find. The ore is said to be similar to that of the Cobalt area. The new field is reached from a point on the Montreal river about 20 miles from Latchford and thence by an overland journey of 15 miles. Owing to this area being within the boundaries of the forest reserves, prospecting is subject to special regulations for the protection of the timber, and great care is taken in the issuing of permits. All claims must be opened up under the supervision of the superintendent of the reserve.

Einar Lindeman, who was commissioned by the Canadian Superintendent of Mines to report on iron deposits near Bathurst, N. B., reports that he has discovered another deposit of much greater extent than those known to exist. It is 75 ft. high, 80 to 100 ft. wide, and extends down for 1,800 ft. to the Nipissing river, which it appears to cross. The discovery is an illustration of the method of examining magnetic iron ore deposits, originated by Dr. Eugene Haanel by the use of magnetometric measurements.

D. D. Cairnes, of the Dominion Geological Survey, who has been engaged during the summer in surveys in southern Yukon, forwards to the Department some important details as to copper discoveries in that district. He writes that west of Whitehorse there are all the makings of a wonderful copper country. One of the most recent and valuable discoveries has been made by

Byron N. White, of Spokane, on the Pueblo. With a small crew, principally doing surface work, he has uncovered an orebody about 250 by 270 ft., and has sunk about 100 ft., but as yet he has found neither wall. The ore is almost solid hematite, heavily impregnated with copper minerals, and will average 4% copper, with some gold. Throughout there are masses and streaks of high-grade ore. Mr. White is shipping 100 tons, and buyers are negotiating for large consignments.

Calumet, Michigan.

Big Production.—Scarcity of Labor.—Operations at the Quincy.—Copper Range Consolidated Increases Output.—Changes at the Ahmeek.—Ontonagon County Mines Doing Well.—Unusual Activity in the Building Trade.

Lake Superior mines produced 20,000,000 lb. refined copper last month, more than was turned out in any previous month in the history of the district. On the basis of 22 cents per pound, which was the average price of Lake brands, the October production was worth \$4,400,000. Notwithstanding the enormous consumptive demand for the red metal and the wish of the mining companies to sell as much copper at the high price as they possibly can, the increase in the total production of the Lake Superior region for 1906 will be slight. Labor strikes, accidents, fires, scarcity of labor, etc., have combined to restrain operations, and some of the important mines will show an actual decrease in their yield for the year. The unprecedented activity in nearly all kinds of metal mining has resulted in a dearth of miners and trammers, not only in the Michigan copper mines, but in the iron districts, and in many other mining regions.

The record-breaking output last month was due primarily to notable increases at the Quincy, Baltic, Trimountain, and Champion mines. The Allouez, Centennial, and Tamarack mines also enlarged their production. Last month's output of the Quincy was, with one exception, the largest in its history. Shipments to the stamp-mill are now at the rate of 3,900 tons daily, larger than ever before, and November should witness a further gain. The new No. 8 shaft on the Mesnard branch of the mine is yielding excellent ore from its lower levels. This portion of the mine adjoins the lands that it is proposed to buy from the Arcadian company. The Mesnard's bottom openings are in good ore. As the Hancock Consolidated cuts off the possibility of the Quincy expanding in a southwesterly direction, its only possible chance to enlarge its property is by buying the Arcadian lands. No. 7 shaft, the Quincy's most southerly opening, continues to yield a large tonnage, but this important opening cannot be sunk to much greater depth, because it has nearly reached the boundary line of the Hancock Consolidated. The No. 6 shaft has lately been yielding mass and barrel copper, which in earlier years formed such a large portion of the production.

All three Copper Range Consolidated mines showed good gains last month. The Champion leads the trio in the amount of its output, but the Trimountain showed the greatest gain. The combined production of the three mines was 3,760,000 lb. refined copper, which is at the rate of 45,000,000 lb. per annum. As the St. Mary's Mineral Land Co. has a one-half ownership in the Champion, this would make the annual production of the Copper Range Consolidated 34,640,000 lb., and that of the St. Mary's Mineral Land 9,360,000 pounds.

At the Ahmeek, production was curtailed by changes in the system of operating the mine, but all the new equipment is now in use and ore shipments will be larger henceforth. Both No. 1 and 2 shafts are working under the new system, but until an additional

compressor is provided it will be impossible for the mine to yield more than 1,100 tons of ore daily. The ore is shipped to the Tamarack mill, where the facilities for stamping it are adequate, as the Tamarack is still hampered by the fire in No. 1 shaft.

The Michigan mine is making steady recovery from the effects of the recent labor troubles. The men who participated in the riot were discharged, and owing to the scarcity of men it has been slow work getting the working force back on a normal basis. Because of the lack of men, surface improvements are slight and a number of drills underground are now idle. Despite these unfavorable conditions, the Michigan is maintaining shipments at the rate of 550 tons per day and as soon as possible they will be increased to 700 tons, which is nearly the maximum capacity of the two heads, which it has under lease at the Atlantic mill. Other Ontonagon county mines besides the Michigan are working short-handed. The Adventure is in urgent need of 25 trammers and laborers. The electric tram line in No. 3 shaft has been completed. This will be a great help in moving the ore and in overcoming the lack of labor. The Mass Consolidated also is crippled by lack of trammers; if men were available the Mass could increase its shipments at least 300 tons per day. The new D shaft was sunk 80 ft. last month with only one drill and a crew of four men, an exceptionally good record. This shaft is penetrating the same kind of ground that was opened in the C shaft at the same depth, which is very encouraging. The shaft is being enclosed and every provision made for the protection of the men before inclement weather sets in. C shaft is shipping a good tonnage of rock of a satisfactory grade, and the surface plant, which embraces some new and economical features, is giving good service.

There is extraordinary activity in the building trade of the copper country because of the prosperous condition of the mining industry. At the North Kearsarge mine the Osceola Consolidated Copper Co. has had 20 new dwellings erected, and 20 houses have been built at the Ahmeek. These are all single houses, with four to seven rooms each, and designed to meet the needs of the increased working forces at those mines. At the Caldwell property, south of the Tecumseh, the Calumet & Hecla is having two residences erected and a boarding house to accommodate 40 men is going up; and at its Gratiot mine, north of the Mohawk, the same company is making similar improvements. The building operations at the Caldwell and Gratiot properties are significant, for they indicate that the Calumet & Hecla plans to work them on a large scale.

Cripple Creek, Colorado.

Litigation Among Lessees.—The Granite Company Ceases Pumping.—

Rich Ore in the Bonanza King.—Stratton's Independence Ships High-Grade Stuff.—More Cyanide Plants.—The Vindicator Makes Interesting Improvements.

The production of the Old Gold mine on Beacon hill, under lease to George Simonton and partners, has decreased during the last month to one-half of its original amount. This is owing to the decision of the District Court, which refused the lessees permission to work the Indicator fraction, at present in controversy between the Henry Adney mine adjoining and the Old Gold. Four cars were shipped during October from this lease which ran 1½ oz. per ton.—A car of \$20 ore per week is being shipped from the Lady Stith claim of the Stratton Estate on Globe hill. James Clifford and associates are subleasing this ground from Keener & Hobson, and are working on a surface cut as well as on the 500-ft. level.—Operations have been resumed at the Jo Dandy

mine on Raven hill after a shut-down of two months. The Jo Dandy Co. has been re-organized with James M. Wright as president and general manager. The Gillett mill of the Cripple Creek Cyanide Co. is being torn down and will be erected on the Jo Dandy ground for the treatment of the lower grade ore. The capacity will be in the neighborhood of 150 tons per day. When the mine is in full running order again it is expected that 30 cars per month of ore, averaging a little over \$20 per ton, will be shipped.

The Granite Gold Mining Co. has suspended pumping operations on the 1,000-ft. level of the Gold Coin shaft. The drowning of the pumps of the Strong mine some months ago left the Granite as the only mine on Battle mountain which was pumping water and, being at the lower level, this pumping has been found to be more beneficial to the surrounding properties than to the Granite itself. The ore below the 1,000-ft. level was not of sufficient grade to warrant the expense of keeping the workings clear of water. It is hoped that in the near future some arrangement will be arrived at whereby all the principal mines on Battle mountain will combine and sustain their various proportions of the expenses of pumping conducted at one of the properties.

A rich streak of high-grade ore has recently been encountered in the Bonanza King claim on Gold hill. Lipscomb & Co. is operating this ground through the Gold hill tunnel. When broken two feet wide the ore ships about 5 oz. per ton. The strike is considered one of the most promising in the camp.—The Mary Casheen mine, situated in the town of Victor, is making regular shipments of fair-grade ore. Harry White, brother of E. Lyman White, State Commissioner of Mines, is operating this property, the principal work being done on the 600-ft. level not far from the shaft. About five cars are shipped every month, the ore being mined 2½ ft. wide and running several ounces in gold.—A new ore-house has been erected on the Ocean Wave claim on Battle mountain, under lease to John Nichols, and shipments will commence shortly. Work is being done at a depth of 300 ft. on a body of ore three feet wide, assays running between \$20 and \$60.—A 21-ton car of ore, giving returns of over 7½ oz., has been shipped during the last week by Stratton's Independence, Ltd. It was obtained from the Washington claim south of the Independence No. 1 shaft in the granite area; this shows that the mine is still far from being worked out.

Sixty tons of ore per day are being treated by the Pony Gulch cyanide mill, which has lately commenced operations. A good deal of experimental work is being done on low-grade ores and an extraction of 98% is said to be made at the present time.

Ore is being extracted from the Los Angeles mine just north of the Last Dollar property, on the south slope of Bull hill. Otto Taubert and John Hodges, who have done so well on the Little Clara mine of the Work company, have this mine under lease. Operations are being conducted on the 300 and 400-ft. levels, where two machines are at work on a fair-sized orebody. A shipment will be made within the next few days.—The Vindicator Consolidated Gold Mining Co. on Bull hill is installing a belt-conveyor in the ore-house. It is to be used for sorting purposes. The conversion of the old Lillie shaft, belonging to the above company, into a gold extraction mill is progressing favorably. The main process will be cyanidation, but an Edwards roaster will be installed, so that sulphide ores may be treated. This roaster is an Australian production, having been invented by Thomas Edwards, of Ballarat. The mill will have a capacity of 150 tons per day. H. A. Shipman is superintending the work on this new plant.

Salt Lake, Utah.

Local Business.—*News From Park City.*—*Strike in the Odin.*—*Operations on Scott Hill.*—*Ontario Adit Not Yet Repaired.*—*The Carisa Finds New Orebody.*—*The Coal-land Cases.*

The ore and bullion settlements reported last week amounted to \$924,700. During the same period 291,580 shares were sold on the floor of the Salt Lake Stock & Mining Exchange for \$279,499.

The ore production of Park City mines last week amounted to 1,830 tons, the contributing mines and amounts being: Daly-Judge, 536; Silver King, 534; Daly-West, 500; Little Bell, 68; Ontario, 66; Kearns-Keith, 56; New York, 57.—Late developments at the Odin mine, near Park City, are of an important character. A drift on the Odin vein has been run for 199 ft. disclosing a breast of ore averaging 19.8% copper, 11% lead and 16 oz. silver. W. I. Snyder, of Salt Lake, is manager.—The directors of the Silver Bell Mining Co. have levied an assessment of 25 cents per share on the issued stock for development purposes.—Much interest is being taken in that part of the Park City district known as Scott hill, situated between the Uintah and Big Cottonwood districts. Important developments have been made lately in the Scottish Chief mine and bond and lease have been obtained by Park City parties on the Brown group, which will form the basis for the organization of the Copper Apex Mining Co. Permanent buildings are under construction and preparations are being made for a vigorous campaign. The lessees are David Scott, A. Pike, and Lee Wight.—The new hoisting plant at the Magnolia St. Louis mine has been placed in position. This company is sinking a shaft.

The stock of the Daly-Judge Mining Co. is to be listed on the Boston Stock Exchange. An examination of the mine is now being made by an engineer, whose report will accompany the application. —The management of the Ontario drainage adit, at Park City, has concluded that it is necessary to run the parallel drift ahead for possibly 150 ft. further to reach the end of the caved section, which means that it will be several months yet before the mine operators can reasonably hope to see the last obstruction removed.

The management of the Carisa Gold & Copper Co. reports the strike of an entirely new orebody on the 300-ft. level; on the strength of this the stock has advanced sharply.—The Victor Consolidated management is preparing to sink the main shaft 300 ft. deeper, and to prepare the property for ore extraction. —The directors of the Beck Tunnel Consolidated and Carisa Gold & Copper companies have posted dividends for payment this month, the former for \$40,000, and the latter for \$5,000. —At a special meeting of the shareholders of the Lower Mammoth Mining Co. the question of increasing the capital stock of the company from 150,000 to 300,000 shares came up for consideration, resulting in the defeat of the amendment.

The Talisman Mining Co. has filed articles of incorporation to operate in Beaver county. P. B. McKeon is president; James Ingelbreten, vice-president; J. W. Stringfellow, secretary and treasurer; who, with P. J. Donahue and Frank Knox, are directors. Salt Lake City is the headquarters of the company.

The arguments in the coal-land cases brought in the Federal Court in this city against the Pleasant Valley Coal and Utah Fuel companies by the United States Government have been concluded, and Judge John A. Marshall, before whom they were tried, has them under advisement. These are the cases in which the Government claimed that the defendants had obtained title to coal-lands through fraud and in addition to having the patents to the same voided, seeks to recover the value of the coal mined therefrom.

Mining Summary.

ALASKA.

The first regular shipment of ore from the Cymru mine to the Alaska Copper Co.'s smelter, under a recent contract, netted 662 tons, containing after all deductions, 49,319 lb. copper, and the valuation based on present prices is \$9,370, equivalent to \$14 per ton net.—The Cuprite Copper Co., operating on the west coast of Prince of Wales Island, is reported to be making an excellent showing. An outcropping of four feet of ore on the surface at an elevation of 2,200 ft. showed a valuation of \$38 per ton.

The strike on Chichagoff island, 40 miles from Sitka, has created excitement. The De Groff claim is the richest of the Chichagoff propositions. Assays run high. One specimen was composed almost wholly of sylvanite. The new camp is expected to help Sitka, that place being the distributing point for supplies.

C. A. Tellier and Lawrence White, members of the Brunner railroad engineering party that has been doing some extensive work in the Catalpa district of Alaska, were both drowned while attempting to cross Bering lake in a severe gale. The news was recently brought to Seattle by George Evans.

ARIZONA.

COCHISE COUNTY.

A new strike of sulphide ore has been made on the 13th level of the Old Dominion mine in the Globe district. The ore assaying from 8 to 20% copper will go direct to the furnaces. —A hoisting plant is to be installed in the Chronicle mine on Lower Lynx creek, and the sinking of the shaft to the 500-ft. level resumed. Two hundred and fifty feet of driving and cross-cutting have already been done from the 85-ft. level. —The daily receipts of the Arizona Smelting Co., at Humboldt, average between 450 and 500 tons; the capacity of the plant is being increased as fast as machinery can be delivered. With the installation of new furnaces, receipts are expected to reach the 1,000-ton mark before the first of the year.

MOHAVE COUNTY.

A party of Eastern capitalists have taken over the mines of J. F. Tomlinson and others situated in the Wright Creek district and are having surveys of the mines made and a town plotted.—The Gold Road Mining & Exploration Co. has declared its third dividend of 25c. per share, amounting to \$75,000.

PINAL COUNTY.

(Special Correspondence).—A great deal of work is being done at the Ash Creek Co.'s mines at Safford. Some months ago a large body of high-grade copper ore was discovered in the Shamrock claim, and it was decided to ship the ore to Clifton for treatment. About 15 tons per day is being sent to the Shannon Copper Co.'s smelter. The entire work is not confined to taking out shipping ore, but a good force of men is kept busy developing other claims in the group. For a number of years Tom Larkins has been in charge of these mines. He has gone through all the discouraging processes that so often swamp young companies in a new and undeveloped region, and he has made a success. The entire district is developing satisfactorily. After starting the concentrator at the San Juan mine a short time ago, Mr. A. Weber soon discovered that he did not have sufficient water. At first the old San Juan shaft, which had nearly 100 ft. of water in it, yielded a supply, but it did not take many days to exhaust that. Then the old Greenough shaft was cleaned out and pumps put to work, and this proved to be sufficient. Then Mr. Weber has a force of men sinking a well at Walnut Springs. Here they have developed what is believed to be sufficient water for all purposes. Early this week a carload of pipe arrived in Safford and was immediately sent to the mines, and is now being laid to conduct the water from the spring to the mill. The water has to be piped about a mile and a half. When they get the connections all made the concentrator will be kept in constant operation.

Phoenix, Nov. 12.

YAVAPAI COUNTY.

An important strike has been made on the summit of Thumb Butte and Copper Basin divide by S. H. Anderson in his new shaft, who, at a depth of 17 ft., uncovered a pay-streak over four feet wide, six inches of which assays over 100 oz. silver per ton, the remainder being second-class ore. These four claims are situated six and one-half miles west of Prescott.

CALIFORNIA

CALAVERAS COUNTY.

An attachment has been levied against the Ohio mine by an employee of Ballentine, who had a bond on the property. The question at issue will be a test of the prevention of laborers from levying upon mines on which have been posted notices that the owners will not be responsible for the debts of those to whom the mine has been bonded.

INYO COUNTY.

Ali H. Hassan has resumed operations at the Bishop Creek gold mines. A new cross-cut adit 700 ft. long is being driven to cut the lode and determine the full width of the ore. Pelton wheels, pipes, compressors, drills, and a Nissen stamp-mill have been ordered. The camp is at an altitude of 6,000 ft. in the Sierras.

NEVADA COUNTY.

A promising mine is being developed in the Chicago Park district, where a five-stamp mill has been recently built to handle ore of good grade from the Ozalli and Shebley property.—New pumps have been installed and are now in working order at the flooded Canada Hill mine. The water has been lowered to the 800-ft. level. The shaft is 1,300 ft. deep, and the work of clearing it will be pushed with vigor, after which sinking and driving will be commenced.

SISKIYOU COUNTY.

U. S. Mineral Surveyor Fitzpatrick, of Oakland, has a surveying party out on Siskiyou mountains, near the Oregon line, fixing boundaries on several claims for the Blue Ledge Co. Snow has already begun to fall at the 7,000-ft. elevation.—Work has been resumed at the McKinley quartz mine on Humbug, the shafts and drifts having been pumped out. Quartz is being taken out under the superintendence of A. L. Hayes.—A large compressor is being installed by A. C. Brokaw & Co. at the Golden Eagle mine on Indian creek. The mill is running continuously on high-grade ore from which \$3,000 to \$5,000 in bullion is extracted monthly.

TUOLUMNE COUNTY.

(Special Correspondence).—The company operating the Clio mine, near Jacksonville, intends to erect a 200-stamp mill on the property in the near future. Much work is to be done besides this. The one-compartment shaft, now 400 ft. deep, is to be enlarged to two compartments and sunk to a depth of 1,000 ft. An adit intersects the shaft 200 ft. below the surface, and from this point up the shaft will be enlarged by stoping. The company also proposes to install an electric plant on the Tuolumne river which will generate sufficient power to run the mill, hoist, compressors, and any other machinery.—The Bagdad-Chase Gold Mining Co. recently made a mill-test on ore from the Soulsby mine and the result is said to have been most satisfactory. The Pennsylvania shaft on this property has reached a depth of 700 ft., and at the Davidson shaft the water has been lowered to the fifth level. A steam-pump has just been installed in the mine to raise the water to this level, from which point it is then taken by a pump on the surface. A large compressor is being installed at the Pennsylvania shaft. The ditch which supplies water to the Soulsby is being repaired and steam is being used temporarily for power.—A small crew of men is engaged in doing development work at the Sullivan mine near Soulsbyville, and the prospects are said to be exceedingly encouraging.

Good reports still come from the Yorktown mine, situated on the Ida Klein ranch, near Stent, in which a rich strike was made several weeks ago. The perpendicular shaft is now 60 ft. deep, from the bottom of which a cross-cut has been driven and the vein tapped. Coarse free gold is scattered thickly in the quartz and the vein is rich almost its entire width. When the strike was made several weeks ago it was believed by some that it was a pocket, so rich

was the stuff, but more recent development proves that this is not the case. Mining men who have examined the property agree that it is one of the most promising new mines in the State today. The owners, Messrs. Lyon, Baum, & McFarland, have equipped the property with a hoisting and pumping plant and will continue development work vigorously.—A hoist to be operated by water-power is being installed in the drainage adit of the Patterson mine. When this work has been completed a winze will be sunk. A Dimmick pulp-sizer and pin-blanket tables are also being installed. Supt. Davies states that grading for the 20-stamp mill is almost completed.—It is reported that operations will shortly be resumed at the Mazeppa, situated south of Stent.

Tuolumne, Nov. 13.

(Special Correspondence).—There is promise of great activity at the Confidence mine in the near future. W. P. Cunningham, of Los Angeles, and others have obtained possession of the property and propose working the mine in a more systematic manner than ever, as well as on a much larger scale than in the past. Work was commenced last week, when a new three-compartment shaft was started at a point 1,200 ft. north of the old one-compartment shaft. It will be sunk to a depth of 1,000 ft., and drifts will be run to tap the old workings and to open up new orebodies. Twenty stamps will be added to the mill, making in all 40 stamps. It is estimated that not less than 100 men will be employed when development work is well under way. W. H. Scott is superintendent. The Confidence has not been worked to a great depth as yet, though it has produced nearly \$6,000,000.—Though it was expected that by this time the water supply for the mines of Tuolumne county would be exhausted, and as a consequence there would be no electric power, both of these are yet available and the prospects are that there will be no interruption of operations on this account this season.—The Pyrenees Gold Mining Co. has let a contract to Gribble Bros. & Muldock, of Tuttletown, to drive a 100-ft. cross-cut adit at the Patterson mine. The object of this work is to tap the Arbona vein, which the company believes passes through its property.—Owing to delay in the arrival of new machinery, several men were temporarily laid off at the Columbia mine last week.—Eastern capitalists have had an expert at the Ohio mine the past few days, making a thorough inspection of the property with a view to purchasing it.—It is reported that several capitalists, with Geo. Ade at the head, are making preparations to begin operations at the Moody. Tuolumne, Nov. 12.

Work has been commenced on the Confidence mine with W. P. Cunningham as superintendent. A three-compartment shaft will be sunk to a depth of 1,000 ft., the point of development being 1,200 ft. north from the old shaft. Twenty stamps will be added to the mill, which will operate day and night.

COLORADO.

EL PASO COUNTY.

(Special Correspondence).—Work is progressing as rapidly as possible on the new mill of the Golden Cycle Co., which is being built on the site of the old Telluride mill near Colorado City. Not much of the machinery of the old company is being used. Several new Edwards furnaces are being installed by Chisholm, Matthew & Co., of Colorado Springs. It has taken longer to erect this plant than was anticipated on account of the slow delivery of material for the building. The 182-ft. concrete stack has been completed by the Weber Steel Concrete Co., of Chicago, and the flues are now being built. It is estimated that the mill will have a capacity of 700 or 800 tons per day; it will probably be ready for treating ore in January. Philip Argall, of Denver, is the chief engineer, and Harry E. Nelson his assistant. John Tait Milliken will have charge of the plant when finished.

Colorado Springs, Nov. 10.

GILPIN COUNTY.

A decision has been rendered by the U. S. Circuit Court of Appeals at St. Louis, Mo., in the Topeka mine case, giving judgment for the defendant, Henry P. Lowe, in the sum of \$182,500 and interest for five years. Attorneys for plaintiff

have petitioned for a re-hearing, which will probably further delay operations at this property.—A deal has been closed whereby Chicago people have become owners of the Senator and Senator Extension mines, situated in Gregory district. Consideration not stated.—The School Hill Mining Co., which has a lease and option on the Cœur d'Alene and Isabel mines, located on Academy hill, Eureka district, is making plans for carrying on heavy operations. Owing to years of idleness, it is necessary to re-timber the main shaft on the Cœur d'Alene from top to bottom. A new hoisting engine and a five-drill air-compressor are to be installed. As soon as the 600-ft. shaft can be unwatered and re-timbered, Superintendent Mackay intends to clean out the various levels, extend them, and sink the shaft considerably deeper.—As fast as the workings of the Saratoga shaft can be relieved of water, men are put to work to clean the levels for regular operations. Lessees are working in the shallow levels and are taking out ore which runs between 8 and 11 oz. gold per ton, besides silver values.—The work of cleaning out the Old Town mine has been completed, and the contractors have commenced sinking their 1,500-ft. shaft. George J. Kimball, Jr., of Idaho Springs, is manager, and James Redding, superintendent.

IDAHO.

Development on the Idora mine is progressing and a cross-cut is being driven to determine the width of the ore-body. A winze is to be sunk from the face of the tunnel, and stoping begun at the 225-ft. level. Tunnel No. 3 is at a vertical depth of 400 ft. A five-drill compressor will be installed as soon as possible.—A vein of galena has been struck on the Independence claim on the Snowstorm vein, adjoining the Lucky Calumet on the west, in a cross-cut at 3,000 ft.—An important find has been made at the Stewart mine controlled by A. F. Heinze, consisting of 30 ft. of solid galena, in a cross-cut. The limit of the adjoining concentrating ore has not yet been reached.

SHOSHONE COUNTY.

A sensational strike is reported in the Wonderful group on Stevens Peak. An orebody 18 in. wide, of chalcopryite and galena has been found of shipping grade.—The Central mine, in the Mullan district, owned by ex-Governor Miles C. Moore, of Moscow, has been sold to W. D. Greenough.—A strike of nearly 18 in. solid ore, which it is claimed carries 10% copper in addition to 20% lead is reported on the Interstate Co.'s property near the head of the East Fork of Nine Mile.

NEVADA.

CHURCHILL COUNTY.

Capt. A. O. Girard and J. H. King, of Oakland, Cal., are at Winnemucca, having, it is said, located the townsite of Bernice and developed a mine there to a point where ore is now being shipped. They are authority for the statement that water has been piped to the townsite, and that the mine is rich in antimony ore assaying 60% purity, without arsenic, zinc, or lead.

ESMERALDA COUNTY.

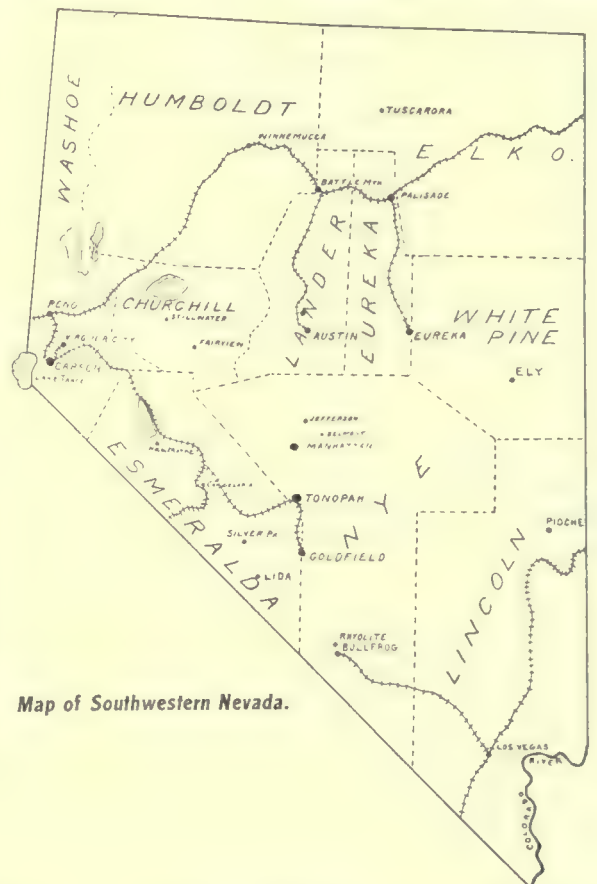

George W. Henderson, of Oakland, Cal., is now at Goldfield after making a trip to Tonopah and from thence to Silver Peak. He reports that there is now plenty of lumber at Silver Peak, and that building operations are being pushed. Work on the mining properties is also progressing in a satisfactory manner.

The merging of four of the richest gold-producing properties in western Nevada has been announced. George S. Nixon, James Wingfield, and others have completed arrangements for the absorption of the Mohawk, Jumbo, Red Top, and Laguna, with the formation of a new company capitalized at \$50,000,000. The par value of the shares of the Goldfield Consolidated Mines Co. has been fixed at \$10. The properties acquired by the company have been taken over on the following basis: Mohawk, \$20 per share. Jumbo, \$5 per share; Red Top, \$5 per share; Laguna, \$2 per share. These shares will be paid for in stock of the new company. It is understood this consolidation is being effected in order to avoid litigation. The lodes are flat, and the question of apex is likely to prove complicated, unless compromised. The Frances-Mohawk Leasing & Mining Co. has installed

the most elaborate machinery in Goldfield. It has one 50 h.p. and two 25 h.p. electric hoists, an air-compressor and a Rand-Ingersoll air-drill. This company also has the distinction of having the only cages and car system in the camp, with which they are able to raise 500 tons of rock daily. The shaft is down to the 280-ft. level; one million dollars in ore has been shipped to date.

LINCOLN COUNTY.

(Special Correspondence).—During the month of October the Quartette Mining Co. crushed in its 20-stamp mill 2,100 tons of ore, which averaged somewhat better than \$25 per ton. Development work is being done on the 600, 700, 800, and 900-ft. levels, and there is more ore in sight now than ever before. G. B. Wilson, of Boston, who in 1898 advised the purchase of the claims which has since developed into the Quartette mine, has taken charge during the absence of the superintendent, Mr. Harrington, who was recently

Map of Southwestern Nevada.

stricken with apoplexy. The typical ore is quartz, containing much iron oxide; the gold yields readily to plain amalgamation. In portions of the vein copper, silver, and lead occur, and such ore is shipped to the smelters. A recent average car of shipping ore gave returns of 9 oz. gold, 8 oz. silver, 12% copper, and 8% lead per ton. C. A. Hopkins, of Boston, the principal owner, is now in Searchlight.—Recent assays from the Stanley Forbes Mining & Milling Co.'s property show an average of \$36 per ton. These claims border on the 4th of July mine.—M. H. Best and M. J. Esberger, from Monrovia, Cal., purchased an interest in the Annette Mining Co.'s property this week.—E. H. Sanford of the Fortuna mine in El Dorado cañon, has purchased a hoist and other machinery. The owners claim that they have the prospects of a large silver mine.—The Wyoming Searchlight has struck water in such quantity as to prevent further sinking, pending the installation of pumping machinery. The water was struck at 245 ft., simultaneously good ore was encountered in the foot-wall of the shaft. A pump has already been ordered, and as soon as the water is under control sinking will be resumed.—Work has been resumed on the Gold Dyke. They are driving to the south expecting to strike the big lode either from the Blossom or the Pompeii, both of which adjoin this property.—The Searchlight Development Co. is building a 50,000-gal. tank to be used in connection with two other tanks in case of fire. A large pump is being put in and

connections being made so that the entire water supply of the town can be connected. These improvements will afford ample fire protection for the camp.

Searchlight, Nov. 10.

A strike has been made on what is known as the Channel City group, consisting of six claims located a little over four miles from Searchlight. The discovery is important because it opens up a new district. John M. Taylor found at a depth of 90 ft. a large vein running \$21 per ton. This appears to prove that instead of the orebodies being confined to the hills and the district lying immediately west, the Searchlight valley for miles is underlaid by gold-bearing quartz.

NYE COUNTY.

Rich copper veins are said to have been found 30 miles southwest from Manhattan, across Smoky Valley to Bank Springs, resulting in a new camp. Over 1,000 claims have been located, and bonds are being taken on everything within a radius of six miles of the original strike. The low hills near the valley are covered with croppings showing the copper stain, and the district is larger than any copper deposit yet found in the State. It is near Bank Springs, which has been a watering place for travelers and cattle-drivers from early days, being on the direct line from Austin to Cloverdale.—Another strike reported 25 miles from Manhattan has resulted in the locating of a townsite named Copperfield. The copper is found as bornite, malachite, and azurite, and even in its native state.

A great scarcity of miners and labor generally is reported at Fairview, Wonder, and Hercules; the shortage in these districts is said to reflect a condition all over Nevada, due in some measure to the recent rush to the Walker Lake reservation, and to discoveries within the confines of the State. This condition is said to be sufficiently serious in the camps named to retard development.

WHITE PINE COUNTY.

The White Pine Gold Mining Co. has bought a mine in the Egan range, about 12 miles from McGills, from which some \$200,000 worth of ore was taken in the old days. Under conditions existing when the mine was abandoned the main body of ore running from \$20 to \$80 per ton became unprofitable to work, the milling process then in vogue being of the crudest, and the nearest railroad 90 miles away. Since the White Pine Co. has taken hold of the property it has opened up two new veins, and has also opened up the contact.

The first payment on the Uncle Sam group of copper mines in the northern part of White Pine county, in the Bald Mountain district, was made at Elko Nov. 6. The purchaser is C. D. Galvin, of Oakland, Cal., who has been developing the property for the past four months. The mine will pass to the Copper Basin Mining & Smelting Co., the name of the company being descriptive of the ore deposit, which is found in a natural basin 1,200 ft. wide between porphyry dikes. This ore, as quarried from surface cuts, has averaged by carload lots 8.83% copper and \$9.63 in gold and silver, as treated at the Salt Lake smelter. Mr. Galvin is also developing the Highland Nevada group of copper mines at Bullion, within 28 miles of Elko.

OREGON.

BAKER COUNTY.

John Arthur, superintendent of the California mine, states that the miners working under his direction have cut the vein 130 ft. from where they had been put at their work in tunnel No. 7.—The vein in the Sunnybrook mine continues to widen, and the completion of a road into the property insures a continuity of development work through the winter.

UTAH.

WEBER COUNTY.

Development work is being pushed on the Napoleon & Maghera mines in Sierra Madre mountain, north of Ogden. At the Santa Maria, in the same locality but in an adjoining cañon, the property of Don Maguire, work is also going on with as heavy a force as can be placed; this property embraces a system of seven copper veins showing outcrops from 20 to 80 ft. The new trail that has been constructed at great

cost has made it possible to take in sufficient materials to insure continuous working through the winter.

WASHINGTON.

OKANOGAN COUNTY.

The Bonita mine on Slate Creek, near Twisp, northwest of Spokane, is again turning out bullion. Besides the 10-ton stamp-mill, a cyanide plant has been installed, and the two save 95% of the assay value of the ore. Ten tons of machinery, including a Lane roller and an electric dynamo of 400-h.p. is being sent to the mine.

SHOSHONE COUNTY.

The Stewart mine is being actively developed with excellent results. The orebody, which was five feet wide in adit No. 1, and 17 ft. wide in adit No. 2, is now an undetermined width at adit No. 3, but, it is reported, so far, nearly 30 ft. of solid shipping galena has been uncovered at the lowest level.

SPOKANE COUNTY.

The United States district court has confirmed the decision of Judge Beatty of Wallace, Ida., in the famous tailing cases, the court ruling that the dam put in by the Federal Mining & Smelting Co. has checked the pollution of land tributary streams for three years.—J. L. Hill, has discovered a vein of pure graphite on Sheep mountain, east of Spokane. The vein from which samples have been taken is 40 ft. wide. There is a parallel vein which carries more than a foot of shipping galena, which is rich in silver and averages \$197 per ton.

The Bunker Hill Mining & Concentrating Co., has made a strike of importance in the Sullivan mine near Wardner, Ida., the orebody, 40 ft. wide, on the lower level being a little more than 1,200 ft. long. The ore reserve is so great that the management may erect another mill to handle it.

CANADA.

BRITISH COLUMBIA.

OUTPUT OF MINES AND SMELTERS IN THE BOUNDARY DISTRICT, FOR WEEK ENDING NOV. 10.

Mines.	Tons.	Mines.	Tons.
Brooklyn-Stemwinder	2,013	Skylark	20
Granby	13,114	Sunset	462
Emma	99		
Le Roi	1,230	Smelters.	
Mother Lode	2,170	Granby	14,500
Mountain Rose	165	B. C. Copper Co.	2,915
Rawhide	462	Domilon Copper Co.	3,222
Total tonnage shipped from mines	18,889		
Total tonnage treated at smelters	20,667		

The strike of the coal miners continues to affect shipments. During the past week only one Rossland mine—Le Roi—sent out any ore, and even its shipments were affected by shortage of cars due to lack of fuel on the Red Mountain railway. The stopes in this mine are full of broken ore, clogging them and getting in the way of the men. Other mines are getting in the same condition and will have to close down until the Trail smelter obtains a supply of fuel. Le Roi will keep up operations, having arranged for a supply of coke from Pennsylvania, which will enable it to run its smelter at Northport.

From the Boundary comes the news of an important deal by which the well-known Cariboo free gold mine in Camp McKinney, some 30 miles west of Midway, has been leased by a syndicate of Phoenix men. The lease includes the machinery and stamp-mill of the Cariboo-McKinney Mining & Milling Co., of Toronto, and was secured by R. B. Boucher, W. S. Macey, L. Y. Birnie, A. B. Hood, and associates. The Cariboo is one of the oldest claims in the Boundary, and has produced more than \$1,000,000 of gold bullion, and has paid more than \$540,000 in dividends. Work was discontinued at the end of 1903, and the extensive underground workings allowed to fill with water, remaining in that condition up to the present time.

The Ymir mine has treated more than 15,000 tons of ore at its stamp-mill and more than 1,000 tons of concentrate have been produced since the beginning of the year. A fine body of ore has been encountered in the west drift from a raise of 1,000 ft., and an orebody has been found at level No. 6 east. The aerial tramway at the Hunter mine will be in operation in a short time.

Personal.

CHARLES HOFFMAN is in Alaska.

J. PARKE CHANNING is in Arizona.

L. H. TAYLOR, JR., is at Mexico City.

A. C. BEATTY has returned from Paris.

F. L. BOSQUI has returned from Nevada.

ALGERNON DEL MAR is visiting Oakland.

J. P. HUTCHINS is on his way to Dutch Guiana.

LESTER W. STRAUSS is in the Yauli district of Peru.

EDGAR RICKARD is visiting New York and Chicago.

BEN. S. REVETT has returned to Breckenridge from New York.

W. H. RADFORD is expected in San Francisco from Alaska.

H. KILBURN SCOTT has left for the Caucasus on professional business.

CLAUDE V. HAINES has gone to Spain as manager of an important mine.

FRANK F. CASTELLO has returned to Colorado Springs from New York.

W. H. PAUL is the new manager of the Dolores mine, in Chihuahua, Mexico.

OSMOND E. LE ROY, of the Canadian Geological Survey, is visiting California.

PHILIP ARGALL is examining mines in Arizona, and will proceed to Nevada.

ROBERT S. BOTSFORD has returned to London from the Sansu mine, in Ashanti.

F. LYNWOOD GARRISON visited San Francisco this week to order mining machinery.

FRANK E. WHEELER, of Creede, Colo., is examining mines in Chihuahua, Mexico.

NATHANIEL WILSON has recently returned to Denver from an extended trip to Mexico.

FRANK C. LORING is now manager for the Trethewey Silver Cobalt Co., at Cobalt, Ontario.

ROBERT SCHORR is building a tramway for the Trinity copper mine in Shasta county, California.

B. F. GRANT is with the Palmerjo & Mexican Goldfields Co., Ltd., at Chinipas, in Chihuahua, Mexico.

J. D. JORDAN has resigned his position with the Mocking Bird Mining Co., of Mohave county, Arizona.

FRED D. FULLER has resigned as manager of the Oregon Smelting & Refining Co., at Sumpter, Oregon.

JOHN L. WITNEY is again superintendent for the Lowell & California Mining Co., at Bighorn, California.

JOHN N. MACKEY has been placed in charge of the Cœur d'Alene and Isabel mines, in Gilpin county, Colorado.

CHARLES FIELDING, managing director of the Mountain Copper Co., is expected in San Francisco from London.

CLAUDE HAER is on his way to Mexico, to take charge of the Cinco Estrellas mine at Pinos, Zacatecas, Mexico.

CHARLES SWEENEY, president of the Federal Mining & Smelting Co., has just returned to Spokane from New York.

WM. H. KINNON, who has been doing professional work in Utah, is now in Wyoming, and will shortly go to California, and from there to Mexico.

C. E. ALLEN, managing director for the United States Mining Co., of Salt Lake City, is at present at Eureka, looking over affairs at the Centennial Eureka mine.

W. S. MORSE, C. W. WHITLEY, accompanied by MESSRS. ECCLES and SPROULE, of the A. S. & R. Co., are at Ely, Nev., paying a visit to MARK L. REQUA, general manager of the Nevada Con. Copper Company.

OSWALD AICHEL, assistant superintendent of the Cia. Minera de Peñoles at Mapimi, Mexico, paid Berkeley a short visit while on his way to the Selby smelting works. Dr. Aichel has been on a trip throughout the western States gathering data concerning the latest smelting processes.

Obituary.

EBEN SMITH, one of the most enterprising leaders of mining in Colorado, died of peritonitis at Denver on November 6. He brought to Colorado the first stamp-mill, hauling it across the plains from St. Louis. He was one of the promoters and builders of the Florence & Cripple Creek railroad, bringing Cripple Creek into touch with outside smelters and reduction plants. Smith was also a pioneer of Leadville, and the first man to unwater the wet mines of that camp. For many years he was interested in the Bi-metallic smelter with D. H. Moffat, in whose mining enterprises he shared to a large degree. With Jerome B. Chaffee, Eben Smith located the famous Bobtail lode in Gilpin county. In Aspen deceased was interested in the Franklin mine and in the Aspen deep-drainage adit, and he operated also in Summit county. Eben Smith was a native of Erie county, Penn. At the age of 19 he was attracted to California by the gold excitement, removing to Colorado in 1860. The closing years of his life were spent in California. He leaves a widow and three children, and he will be mourned by a wide circle of mining men to whom he was a friend. In him Colorado loses one of a group of enterprising operators—ready to grubstake prospectors and to buy mines in new districts—who did much to stimulate the development of the State.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE building of the United Engineering Societies at New York is now receiving its interior finish, and it is to be ready for inspection in December.

DURING the first nine months of this year the Bendigo district, in Australia, produced 172,678 oz. gold. The mining companies paid £206,252 in dividends and levied £156,247 in calls.

THE solution of potassium cyanide in pure water, from which all other substances are excluded, is entirely *without* action on metallic gold. The reaction begins only when air is supplied.

CONCRETE made of broken or crushed brick instead of stone gives excellent results for some purposes; but it always requires a larger proportion of cement than when less porous material is used.

THE Oliver Iron Mining Co. at Coleraine, in the western Mesabi range, has undertaken to remove 13,000,000 cu. yd. earth. The intention is to strip 80 acres to an average depth of 80 ft., in order to uncover a body of iron ore estimated to be at least twice as large as the overburden covering it.

ON the whole, with low-grade ores and dilute solutions of potassium cyanide, the cyanide solution itself will, if properly aerated, carry oxygen enough to dissolve the gold; so that artificial oxydizers are seldom needed, unless there is some reducing agent present in the water or the ore which will absorb the oxygen.

THE chemical reaction explanatory of the precipitation of gold in dilute potassium cyanide is supposed to be represented by the formula

but, like all such formulas, it is inadequate to represent all the changes that occur.

WHEN copper is fused it possesses a sea-green color. Molten copper has the property of absorbing certain gases, such as hydrogen, carbonic oxide, sulphurous acid, etc., which it sets free again on solidifying. This causes serious difficulties in making castings, and requires the employment of special precautions to prevent porosity.

WHEN a dynamo is to be operated by a separate engine not on the same bed-plate, the foundation should be made common to both, or if separate foundations are necessary, set the two machines on a frame made of substantial timbers, or steel I-beams, which may rest on the double foundation. In this manner the engine and dynamo may be kept in perfect alignment.

THE cost of quarrying or excavating porphyry (for silicious flux in smelting), should not exceed seven cents per ton under favorable conditions. This would include the cost of blasting and delivering on cars. The most economic method is to drive short tunnels and blast several thousand tons of rock and handle the debris with a steam-shovel, or chute it directly into cars.

THE surveyor should keep his plans up-to-date and see that the men in charge of the mining operations fully understand their instructions; for many mining bosses of considerable experience get entirely wrong notions of the shape of their workings and are often too proud to ask for information. The surveyor, without assuming a

know-it-all attitude, can, from the specialized nature of his work, often make useful suggestions in regard to the exploration of a mine. By working always in harmony with the other officials of the mine, he can further the interests of all concerned, both employers and employees.

THE most frequent cause of collapse among water-tanks is the corrosion of the hoops. This is a flat wrought-iron band, $\frac{1}{2}$ to $\frac{3}{4}$ in. thick, which is seldom painted, so that it becomes subject to corrosion both from the outside and the inside. Hoops should never be less than $\frac{3}{4}$ in. diam., and they should be made without welds and thoroughly painted before and after erection.

THE power required to operate a belt-elevator is comparatively insignificant. The apparatus itself is in equilibrium, and only such power has to be applied as is necessary to lift the ore and overcome the friction. The theoretical requirement of power to lift 10 tons per hour to a height of 40 ft. is only 0.4 h.p., and allowing an equal amount for friction, the total is only 0.8 horsepower.

ALL minerals found in placers are not gold, nor even 'black sand,' nor platinum. In some of the placers of Colorado, especially those of glacial origin, there are found galena, zinc-blende, silver, and even copper carbonate and sulphides. The occurrence of these diversified minerals indicates that there has been but little movement in the debris since it was broken from the lodes on the neighboring hillsides.

EXPERIENCE generally has shown that it is necessary to grind pyrite very fine before high extraction is possible. In Western Australia there are a few exceptions, and also to a less extent, in South Africa. Fine grinding, not only of pyrite, but of silicious ore, is now commonly practised in Western Australia and also in California, and the best results everywhere will probably be obtained when pyrite is ground to 200 mesh.

IN making screwed joints in piping, it is best to use some compound, because pipe fittings and the threads on pipe ends are not always uniform, even when coming from the same maker. They rust and accumulate dirt before being used, so that threads do not fit precisely and fittings will leak. Most steam fitting is done in red lead. Graphite and oil are also employed and are efficient. Black asphaltum, about as thick as melted butter, is similarly successful.

AN ORE containing galena, sphalerite, and stibnite, with gold and silver is generally amenable to treatment, for such ores are successfully concentrated at various places. Ordinarily the galena, the specific gravity of which is 7.5, may be separated from the gangue and the other sulphides by hydraulic concentration. The blende and stibnite should be passed through an electro-magnetic separator, which should effect their separation. The specific gravity of blende is about 4 and of stibnite 4.5; they cannot easily be separated on vanning machines or concentrating tables.

As between perpendicular and sloping elevators, the former generally adapts itself better to the construction of a building and permits a simpler arrangement of the machinery; it is less expensive in first cost and less expensive to keep in repair than the sloping elevator. The chief drawback is in maintaining a proper tension in the belt, as it stretches. This must be arranged by using a tightener, which is usually provided in the form of an adjustable boot. In the case of the sloping elevator, inclined at from 10 to 15° from the vertical, or more, the belt is self-tightening.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Tube-Mill Lining.

The Editor:

Sir—After reading about the proposed tube-mill lining to be used at the Waihi mine, in New Zealand, I thought it would be of interest to your readers to know of my experience with practically the same lining. We have installed a 12-ft. mill, made in the shops of this company (Oriental Con. Mining Co., of Korea), and, being slightly out of the world, it would have been a great saving to line our mill with ordinary hard quartz and cement such as described in the MINING AND SCIENTIFIC PRESS of July 28, 1906.

About nine months ago it occurred to me that if we could utilize our hard quartz, together with a proper

1, 2, 3, 4. Rails.
5. Quartz.

6. Mortar.
7. Shell.

cementing material, it would make an ideal lining for a tube-mill. The most important point was how to hold it in place within the tube. The mill was put together in three sections or sheets of iron and all well riveted hot. These sections we well knew would not be as good as one continuous sheet or tube, for they were liable to spring a leak around the rivets. This would mean a considerable

FIG. 2

loss in our case, as we are grinding concentrate to a slime in strong cyanide solution. Therefore an arrangement that would give strength to the mill as well as hold in place the 'bull' quartz lining was wanted. Sixteen-pound rails were riveted lengthwise in the tube, six inches apart and around the total inner circumference. Diameter of tube is three feet. Fig. 1 and 2 show the arrangement of rails and the way the quartz and cement was held in place.

The best quartz for the purpose was found at the Tabowie mine. It was hard but not brittle, which seemed to be an important point in such a lining. All cementing material was made up of equal parts of hard coarse quartz, sand, and cement. Special care was taken to have the sand clean and fresh. A layer of cementing material was first put between the rails next to the shell, and spread out evenly. Next, large pieces of 'bull' quartz, 2 and 3 in. diam. were pressed into the cement as compactly as possible, and between these larger pieces smaller quartz was filled in with the cementing material. It was all tamped well, so as to fill the spaces with cement. Another layer of cement was spread evenly over the top and another layer filled in as before. The two layers brought the quartz about two inches above the rails, the upper layer serving as a protection. Every little space between the large quartz was filled with quartz and cementing mate-

rial. Finally, on top of all was placed the mortar; this also was well tamped. The surface was smoothed with a trowel and then allowed to set. A strip or one-third of the mill was lined at one time. After two days it became sufficiently hard so that the mill could be turned over and another one-third lined in the same way. When the lining was complete, it was allowed to set for six weeks. This was more than was really necessary to become hard, but we wanted to have it thoroughly dried out, so as to have it in the best possible condition to wear. The inner diameter of tube was now about 2 ft. 3 in. Ordinary bull quartz, the same as used for the lining, was broken up in 2 and 3-in. pieces and used as pebbles for grinding, which proved to be very satisfactory. The tube was filled just a little over half full, which amounted to 1½ to 2 tons of pebbles. The material ground in the mill was concentrate, cyanide solution being used.

Now, in regard to the wearing of the lining, I can say that it was by no means satisfactory. At the rate it was wearing it would have only taken about two weeks to cut away all the lining. It was rapidly undermining the larger pieces of quartz—that is, the cementing material was gradually cut out. Wherever there was a space of cement between the quartz that was possible to wear, it was sure to be gradually worn away and cut out, allowing the quartz pieces to fall out. You cannot imagine the beating and wearing action the pebbles have on that cementing material. The quartz in the lining will stand alright, but the thing is to keep it in place. Even with silex linings, where the best quality of diamond cement is used, and where all the bricks are made to fit as closely

FIG. 3

1. Steel plate liner. 3. Steel rail. 5. Iron washer.
2. Countersunk head. 4. Vanner belt washer. 6. Nut.

as possible, the pebble will, in spite of all, wear away some of the cement to a certain depth. Now, how can you expect ordinary or portland cement to stand where the spaces between rough pieces of quartz are greater? It may be easy to think in the first place that this lining is going to hold, but to make it is another thing. The lining appeared to be very hard before using and certainly ought to have been, for it had plenty of time to set. The principle of the lining is all right, but I am afraid we will have to find something a good deal harder than portland cement for a cementing material.

Cast-steel liners were the next to be tried, as we had on hand enough of stamp-battery liners (4 ft. by 9 in. and 1 in. thick) for our purpose. Before putting them in place the old quartz lining had to be removed from between the rails by means of a single jack and moil. It was no easy task, for it was hard and the rails held it in securely. The rails were left in and the steel plates put on top, being held in place by bolts with counter-sunk heads. The bolt extended out through the shell, and over this was put a washer made from a piece of old vanner belt. On top of this was an iron washer and then the nut. There were two bolts, one in each end of the plate, to hold it in place, and both were screwed down tightly. After a day or so of running, they were screwed up again. Probably it was necessary to go all over the bolts on the tube-mill a third time, but after this we never had any trouble with bolts leaking or getting loose. It was absolutely necessary to have vanner-belt washers next to the

shell. Fig. 3 will show the method of holding the liners.

The rails give the tube great strength, especially where it is put together in three sections. With these in place, there need be no fear of leaks starting around rivets, especially if the riveting has been done well.

These steel liners have now been in use one month and show only a little wear. At the present rate of wear these liners should last at least six or seven months more. About ten tons of clean concentrate per day pass through our 12-ft. mill. Two tons out of the ten are caught by the spitzkasten box and passed through the mill again as coarse concentrate, making eight tons ground to slime and passing into the agitators per 24 hours. The question of a cheap lining in out-of-the-way places like Korea is certainly one of great importance to tube-milling. If more would give their experiences concerning different linings, it would be of great value to us all.

Taracol, Korea, September 29.

Machinery Merchants and Metallurgists.

The Editor:

Sir—I read with considerable interest the remarks of W. H. L. which appeared as a letter in your issue of October 27 under the above heading.

While there is a great deal of truth in some of his remarks, he imagines that with one fell swoop he has unearthed a great evil which has but one cause, and for which he can see but one remedy. He presumes that all consulting engineers are above suspicion and almost infallible, and that every mining-machinery house takes pleasure in cheating its own customers.

As the representative of the engineering department of a large mining-machinery house, I take exception to your correspondent's attitude of mind and claim that it is unjust and that his remarks are misleading. I admit that there are abuses, but are the machinery sellers the only individuals to blame? Unfortunately the evil is a very general one and is found throughout the whole great sphere of commercial industry, wherever exchange and barter go on, whether the product be the brain and experience of the consulting engineer, the mines of the miner, or the machinery of the manufacturing house.

No doubt the large proportion of properly qualified mining engineers and metallurgists are good, honest, capable men, who do their best for their clients, but, unfortunately, many of them work directly into the hands of the salesman who will give them the highest commission. Others work deliberately into the hands of large corporations and deliberately turn down a good mine or a good process, if they think there is any chance of its being bought in cheap by 'friends.' Still others are professional 'hedgers' and will not handle anything that does not promise to redound to their credit, and thus the unfortunate mine owner who comes to them for advice is left in despair.

I can see no logical reason why the mining-machinery houses should not employ competent engineers to represent them and assist their clients. W. H. L. has no right to refer to this as "the gradual intrusion of the mining-machinery houses into the special field of the metallurgical engineer." If I am not mistaken, in the early days, many of the best men owed their training to a mining-machinery house and afterward branched out into independent consulting engineers. It stands to reason that a capable engineer in the employ of a large house has excellent opportunities to collect data and information which is invaluable to a prospective purchaser, and with the present ill-defined boundary lines between the engineer, the engineer contractor, and the

purely manufacturing firms, it is not possible to refuse information to a customer.

The machinery house prefers to quote against a specification drawn up by an independent engineer; that is plain sailing and relieves them of all responsibility, but, like the reputable engineer and metallurgist, they have a future to think of and must make every effort to secure good results for their customers, or their failures will soon tell against their chances for future business. I have seen a good many plants condemned where, as W. H. L. points out, the fault was in the misapplication; and I have also seen a plant of machinery designed, purchased, and installed on the advice of a very well-known metallurgist, for the purpose of developing a mine, which I, as a mining-machinery representative, would have been ashamed to recommend to a client in view of the conditions extant at the mine in question. The development work was a failure, the mine was unjustly condemned, and the unfortunate owner was left in a hole about \$80,000, when, if the 'metallurgist' had been thrown on the scrap heap and a little common sense used, the mine could have been made a success.

In regard to the establishment of ore-testing plants, I can see no reason why a manufacturing house should not maintain such an institution; in fact, it becomes almost a necessity when machinery houses are owners of special patented machines. Let us presume that a prospective customer sends down a sample of his ore with the inquiry "How can your machine handle my rock?" What could the house do but undertake a test and give some sort of a guarantee as to results?

It is also necessary for the convenience of customers who wish to carry on tests and experiments subject to their own supervision, and it in no way interferes with the legitimate business of the consulting metallurgist. On the contrary, it merely assists the re-solution of the preliminary problems and avoids the possibility of some of those fatal mistakes which W. H. L. takes so seriously to heart and with good reason.

The interest of all three parties under discussion may be safe-guarded by the use of a small quantity of that well-known but very scarce commodity, common sense. If this is applied with judgment by the mine owner, he will first go to a reputable machinery house for his preliminary estimates and to get some general idea as to whether his problem is a simple one or is likely to prove complex and involve more capital expenditure than he has at his disposal. When the machinery house finds that a customer wishes to get a great quantity of engineering knowledge for nothing, and that the problems to be faced are more within the scope of a consulting engineer, they will use the same common sense and refer their client to the best and most competent man that they know for the particular line of work under consideration. Further, I think that it may be generally conceded that it is the almost universal practice of reputable manufacturers to pass their customers along to each other when they know that they do not manufacture the machinery best adapted to their requirements.

I shall be pleased to hear further discussion of this interesting subject and will endeavor to reform my moral code in accord with the light that may be shed.

San Francisco, November 9.

Who Is a Mining Engineer?

The Editor:

Sir—A railroad engineer is one who builds a railroad; a mechanical engineer, one who builds machines; a civil engineer, one who builds roads, dams, etc.; and so on, through all the profession of engineer—electrical, chem-

ical, metallurgical, etc. An engineer is the man who *does* things, who conceives and carries out works and methods of public utility that benefit the human race and make for progress. Therefore a mining engineer is a man who builds up the mining industry by developing and bringing into use the mineral stores which the "Great Architect of the Universe" has placed in the earth for the service of man. Titles acquired by examination or purchase or in other ways are of small account. I have several of them, but they did not make me a mining engineer. I owe a debt of gratitude to, and have unbounded respect for, the real mining engineer who has brought a mine to a successful issue, and I think he has more right to place E. M. after his name than many a college graduate. There is no branch of the great engineering profession that requires such a many-sided man as that of mining engineer, and all that colleges and technical schools can do is to lay the best foundation possible. A man may graduate in art, science, literature, etc.—but that any college can grant a degree as 'Engineer' by mere examination at the end of a three to five years' course is preposterous and misleading. An engineer is emphatically the man who *does* things—and until a man has built a railroad or some public work or 'run' a mine or smelter, etc., and shown that he is capable of translating learned terms into successful action, he has no right to call himself E. M., C. E., M. E., or any other kind of E.

WALTER E. KOCH.

El Paso, November 5.

Sectional Gold Dredges.

The Editor :

Sir—Continuing the discussion of Mr. Curle's article, I desire to say that the question of sectionalizing a dredge for mule transport over such rough country as the Andes is interesting, and there is no doubt that this may be accomplished, provided timber for the hull and spuds is available on the east side of the range, where a wider road than a bridle-path could be built. As to dividing it up in eight pieces, that is of course out of the question, because the machinery alone for a 3½-cu. ft. bucket dredge would weigh in the neighborhood of 160 tons, exclusive of motive-power machinery. One-eighth of this weight is 20 tons, and two mules, under such circumstances as stated, could not possibly take a load of more than about 600 pounds.

The following particulars of an interesting case of a dredge being sectionalized for a property on the Gold Coast are given me by Mr. C. Cline, formerly connected with the Risdon Iron Works: An English company, known as the Goldfields of Eastern Akim, about the year 1900, gave an order to the Risdon Iron Works, of San Francisco, to build a dredge for transportation from a point near Accra, on the coast of Ashanti, to a point some 60 miles inland, where an alleged dredging tract was situated. The native method, of carrying the load on the head, was to be used, and, as a good porter will only take about 200 lb. in this manner, it will be readily understood that the parts had necessarily to be light. Of course, many pieces could be slung between several natives. It is related that a case is on record of a gigantic native from the Sahara carrying 400 lb. in this manner.

It was intended to construct the hull on the ground, from native timber, so the question of lumber was eliminated. The tumblers were built in 25 to 30 pieces each, and as the upper one weighed 4,000 lb., this made the heaviest part not over 200 lb. The ladders, trommels, buckets, etc., were naturally all easy to sectionalize. As the dredge was to be run by steam, a boiler was necessary, and the intention was to transport the plates separately, the riveting to be done on the ground. The

heaviest single pieces were the engine cylinders, which weighed about 1,000 lb. each. The tumbler castings, instead of being pressed onto the shaft by hydraulic press, were to be heated, the expansion being sufficiently great to give a tight fit when cold. At the last moment, when all was ready, orders were received by cable to rivet all sections together and ship as an ordinary dredge. This was done and the machinery was dumped on the beach at Accra. Internal trouble had arisen in the company meanwhile, and there was a stop to further progress. Some of the dissentient members formed a new company and ordered a complete dredge from the Risdon company, which it was proposed to transport by means of traction engines. This machine was also built of 3½-cu. ft. bucket capacity. Accordingly, three years after the first dredge had been shipped, a properly metaled road was built into the property at a cost, it is said, of £30,000. The work was elaborately done, the road surface being actually graveled, though the native carriers unfortunately avoided this and took to the old trail, preferring it because the gravel hurt their bare feet. Three traction engines—each of different design and of uninterchangeable parts—were sent out and proved to be a failure. One, I believe, only reached a point seven miles from the shore. Mr. Cline was finally sent out, and he transported and erected the dredge in six months. All circular parts were cased in wood and rolled along the road. The boiler-drum, to allow for the camber of the road, was built up with wood at the ends and also rolled in. The timber for the hull and framing was cut and framed on the ground, and the stacker-ladder was built of wood. The boiler sections were riveted and the 16-ft. tubes put in on the spot. The ground to be dredged was 14 ft. deep at the place of building and Mr. Cline ran the boat for four weeks after it was erected, but I have been unable to learn of its subsequent fate. As the ground had never been either drilled or, in fact, prospected, I fear that it is not hard to conceive the outcome.

The parts and weights for a 3½-cu. ft. dredge, as usually provided, are given in the following table, with the corresponding number of sections and weights into which each could be divided. The ground, however, to be worked by such a machine far away from proper repair facilities, etc., would require to be extremely rich to allow the feat to be undertaken, and it is doubtful even then whether it would prove practicable.

The following table* will give an idea of the weight of a 3½-cu. ft. Bucyrus dredge and the divisibility of its parts :

Name of part.	Total weight lb.	Number of pieces and their weight.
Upper tumbler.....	6,500	Can be cut in 20 pieces, one of which will weigh 1,000 lb., the rest will be below 300 lb.
Lower tumbler.....	4,500	Can be cut in 13 pieces, three of which will be about 700 lb., the rest below 300 lb.
Digging ladder.....	28,000	Two pieces of 600 lb., the rest about 300 lb.
Digging buckets (3½ ft.)	83,000	Bottom about 320 lb., each hood 135 lb., lip 120 lb.
Screen, stacker, and parts	16,000	Eight pieces would weigh about 600 lb. each, all other parts 350 lb. and less; 70% less than 300 lb.
Gearing	30,000	Eight parts would weigh about 700 lb. each, the rest from 350 lb. down; 50% less than 300 lb.
Engine or motors.....	15,000	Two pieces about 1,000 lb.; two pieces about 600 lb.; 50% below 350 lb.
Boilers	8,500	All below 350 lb.
Pumps	300	
Winches	42,000	Two pieces 600 lb. All other parts below 350 lb.
Other parts.....	7,600	All below 350 lb.

D'ARCY WEATHERBE.

Bisbee, November 3.

Milling Gold Ores.

Written for the MINING AND SCIENTIFIC PRESS
By ALGERNON DEL MAR.

The fact that the stamp-mill still holds the field for the general milling of gold ore, and that the battery of five stamps has been found the most efficient combination, is worthy of comment, for many other types of machines have been tried and found wanting. Although as a simple pulverizer the stamp-mill is not an economical machine, its simplicity and the ease with which repairs are made more than offset any drawbacks. If well taken care of, there are only two wearing parts, the shoe and die, both simple forgings and easily replaced. The guides, tappets, and cams may last for years if ordinary care be taken, while broken stems are generally caused by poor material or carelessness, by allowing too much play in the guides or permitting pieces of keys or drills to get into the mortar. The wearing parts rarely cost more than 10c., and often as low as 5c. per ton of ore crushed, which is difficult to surpass, considering that the minimum amount of labor and other materials are necessary in conjunction. But when the stamp-mill is considered not merely a pulverizer, but a metallurgical apparatus for the extraction of precious metals, it is found that the simplicity of construction lends itself to a complexity in operation.

It is often commented upon that no material advance has been made toward a perfect milling machine. In one respect this may be true, for the stamp-mill is essentially the same as twenty years ago, the improvements being heavier parts and better foundations. As a fine pulverizer, the stamp-mill has been replaced or used in conjunction with re-grinding machinery such as pans, Chilean mills, and tube-mills, but only in cases where it is found profitable to treat a slime product by chemical means, and where the gold left in a sand product will pay for re-grinding and chemical treatment. This is seldom the case in California, except possibly with oxidized desert ores, but in any case it requires careful testing as an arithmetical equation.

The unit of 20 stamps on a cam-shaft has evolved to ten and frequently to five, and the number of stamps in a mortar has been changed from four to five; these may seem minor factors, but some years of experience were necessary to demonstrate which combination would be best. Units of less than five stamps have been tried, and, with rare exceptions, they have been supplanted by the regulation number, for not only are the latter better amalgamators, but require less labor to run. Take alone the question of screens and feeders, a five-stamp mill requires one-fifth the amount of work of five one-stamp mills; at the same time, the five one-stamps will crush half again as much as the five stamps.

Two objects are sought in every milling operation, the comminution of the particles of ore to such a state of division that the precious metals may be separated from the enclosing material and the extraction of these precious contents. A machine that will accomplish the first purpose may not fulfill the second. This fact is important and is often overlooked.

Unless in the hands of a competent metallurgist, it were best to install units of five stamps with a roomy mortar. This style of mortar can be filled in with a false lining, while the narrow-discharge mortar cannot be enlarged should the ore require the change. Other machinery will treat some ores better than a stamp-mill, but without detailed tests it should not be erected. A five-stamp battery, while not crushing as much per stamp as smaller units, is a far superior amalgamating machine. While in a five-stamp battery the pulp is

washed back and forth, and remains some time in the mortar subject to the chemical or mechanical action of mercury or amalgam, in a one or two-stamp machine the pulp is expelled from the mortar as soon as it is ground fine enough to pass through the screen and overcome the height of discharge—conditions which are detrimental to inside amalgamation. It is not contended that this is the case with all ores, for where the gold is especially free and amalgamates easily on the plates, say, for example, gravel ores or where the principal extraction is by potassium cyanide, or where the values are almost entirely in the concentrate, a simple crushing machine may answer all requirements, but with most gold ores the metal is in a fine state of division or is mechanically covered or partially coated with some non-amalgamable material.

The general proposition may be thus stated, that while gold has a great affinity for mercury, it resists amalgamation unless the conditions are favorable to a union. These conditions are the physical state of the particles of gold as governed by the size to which the ore is crushed and the manner of crushing, the removal of all substances prejudicial to a combination of the gold with the mercury, and the condition of the catching surfaces. Now, it is obvious that a particle of gold has a better chance of being held by a particle of mercury the more often it is brought into mutual contact, and this is the case with milling most gold ores. Take, for instance, a one or two-stamp battery, the gold is forced out of the mortar almost as quickly as it is freed from the enclosing gangue. If a fine particle, it must catch on the outside plates or float off. If covered with iron rust or other material so that the mercury cannot find a bright portion to hold on to, it must necessarily go over into the tailing. The same is no doubt true of every battery, but in a lesser degree the more often these particles of gold are brought in contact with a bright particle of mercury. Once outside the mortar, the depth of water on the plates being so much less than in the battery, there is more chance of the particle of gold getting hold of air particles which aid the floating. Once caught inside the mortar the gold is as good as coin, but once outside it is a fight between the millman and all contrary influences; sometimes the fight is won, and sometimes the aid of a cyanide plant is brought into play as a last resort.

The scouring action inside the small battery is intensified, and it is difficult to obtain a good inside plate either of copper or corrugated iron, while with a five-stamp battery half of the gold content can usually be caught inside, and the plates kept bright and completely covered with amalgam. This is important, for as gold has a greater affinity for amalgam than mercury alone, the particles of gold inside the mortar are in the best environment to be caught.

Now, the small-unit batteries, lacking this ideal condition, are at a disadvantage in respect to refractory or fine particles of gold. By covering a copper plate with a screen (with half-inch holes) when the gold is bright and easily caught, good inside plates may often be obtained, but with low-grade ore or where the gold is not easily amalgamated, the scouring action will often keep pace with the deposition, in which case the inside plates had best be discarded, for scoured amalgam is difficult to catch on outside plates. Some gold particles will amalgamate more readily if dashed against an amalgamated surface, and for these particles inside plates are particularly efficient. This trivial peculiarity may be a determining factor in favor of a battery that provides this condition. I do not wish it to be understood that inside amalgamation cannot be conducted with a small-unit battery, or that it is always advisable, but where

advisable, the five-stamp battery is infinitely better; on the other hand, where fast crushing is essential, the smaller the unit, the better the result in tons crushed.

That a crushing machine is not necessarily an amalgamator is a fact; for example, in an experiment with a roller mill crushing dry, mixing with water and running over copper plates, less than 30% of the gold content was caught, while the same ore, after being reduced in a five-stamp battery over the same plates, has yielded over 80%. This experiment may be compared with one where the gold in a hematite-lime ore, while giving as good an extraction with a stamp-mill and cyanide plant, was more economically worked with a roller mill and cyanide attachment. This emphasizes a former statement that unless in the hands of a competent metallurgist, it were best to be on the safe side.

Several mills in northern California, originally built with quick-crushing stamp-mills, have changed to the five-stamp type, with good results, and this is an experi-

charge of crushed material takes place, the stampstriking the dies in spite of the amount of ore in the mortar. But from the point where the discharge and drop are equal, to the point where they are at their maximum ratio, the relative fineness of the material issuing from a mortar increases as the discharge increases. By regulating these two factors, of screen and discharge, any size or any proportion of sizes of particles of pulp can be had at pleasure, but the output is decreased in proportion as the discharge is deepened.

Extreme comminution has been advocated by some who claim that if an ore is pulverized fine enough, the gold will either settle in the mortar or will amalgamate on the plates. My experience, in Nevada and California, is directly otherwise; this extreme state of division causes flouring of both gold and mercury, which are then most difficult to catch, the tailing showing an increased value. For example, with an ore in Esmeralda county, Nevada, a 50-mesh screen crushing about two tons per day per

An Old Patio.

ence that is repeating itself wherever the physical and chemical nature of the gold requires a particular state of division and offers a resistance to a combination with mercury. This resistance may be caused by a coating on the particles of gold or by some chemical constituent of the ore that affects the absorbing action of the mercury. The first condition is principally affected by the crushing, while the latter depends upon the millman.

While the general statement holds good that the size of the particle issuing from a mortar varies as the size of the screen-opening, it is seen in practice that the number of such particles and their relative sizes, depends upon other factors—that of the depth of the die below the screen-opening called the ‘discharge’ and the number and character of the splashes caused by the falling stamp. While the size of the screen-opening regulates the largest particle issuing from the mortar, it does not regulate the number nor proportion of the smaller sizes. This is controlled almost entirely by the depth of discharge. For example, with some ores when the discharge increases much above the height of drop, the feeders refuse to work automatically, the mortar rapidly fills up, and no dis-

stamp, gave \$12 to \$15 tailing, while the same ore, with a 30-mesh screen crushed about three tons per stamp, and the tailing fell to \$6 to \$8. This experience is one that is rather puzzling. Now, if the \$6 to \$8 tailing will cyanide, well and good, but if the amount left after cyaniding the sand will more than cover cost of re-grinding and treatment, and the slime gives a good extraction, this is a case for sliming the whole product, not in the mortars, but as a subsequent treatment.

Quick-crushing batteries are often used on account of the small outlay of capital necessary and with the idea of extracting sufficient metal to buy new machinery of greater capacity, but to the very fact that these machines are poor amalgamators must be debited the general result that the money for such improvements is not forthcoming at the expected time. The point I wish to make is, that for crushing fast a small-unit battery is preferable even with the increased attendance necessary, but whenever the question of amalgamating the pulp is considered, the efficiency of the five-stamp battery as an amalgamator will more than outweigh the increased tonnage of the one, two, or three-stamp machines.

Three Weeks in Mexico---XI.

The Patio Process.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

The pride of Pachuca is in its *haciendas de beneficio* or reduction works, of which there are seven large ones. Six of these are in operation and they treat 5,000 tons per week. Three of them are custom works; those of Guadalupe, La Luz, and Loreto are not. At the entrance of the *haciendas*, and even of private residences, one sees the big iron hoods of the mercury retorts. They

ported on a frame. The concentrate is shipped to Europe; it contains 14 to 15 kilo. silver and 100 g. gold per ton. The yield (from 900 tons of crude ore) is 21 tons per week, of which 13½ tons comes from the vanners and 7½ tons from canvas tables that receive the tailing from the vanners.

The tailing left over from this concentration process goes to vats or bins; these are structures built of masonry, 4 to 5½ m. deep. Here the pulp settles and the water is drawn off to a well, from which it is pumped for use in the mill. Stated briefly, the process of ore reduction consists in grinding fine with Chilean mills, extracting the heavy sulphides (with their associated gold) on concentrators and then treating the tailing (containing the bulk of the silver) by amalgamation on the *patio*.

On the flat ground below the terraced slope forming the site of the mill just described, there stretches the broad expanse of the *patio*, where the process of that name is carried out. *Patio* means a yard or enclosure, and the process derives its name therefrom. The *patio* of the Hacienda de Guadalupe is the size of a city square, it is paved with stone and divided into rectangular spaces, 30 by 25 metres, in which twenty separate charges or *tortas*, each weighing 300 tons, are undergoing various stages of treatment. Each bin or vat that holds the pulp or tailing, from the concentrators, has a vertical opening 5½ ft. wide which is kept closed by a series of boards (6 to 9 in.) These are removed one by one so as to allow the sludge to flow

along the canals—3 ft. high, 6 ft. wide and built of stone—that lead into the *patio* itself. The flow of the sludge is assisted by a scraper (*camon*) pulled by a horse. This scraper is a plain plank, two inches thick, to which chains, connecting with the traces, are attached, as shown in the accompanying photograph. *El camonero*, the horse that does this duty, must be strong, for the work

are buried in the ground, one on each side of the gateway and, being 5 to 5½ ft. long, they have the appearance of spiked guns.

The Hacienda de Guadalupe treats 900 tons per week, the ore of the Santa Gertrudis and Guadalupe mines. At the mine the ore is broken by hand, and picked over; the 'best selected' assays over 10 kilo. silver per metric ton and is sent to Europe, the second class, carrying less than 10 kilo. but over 2 kilo. per ton, is shipped to the smelter at Monterey, while the mine-run, containing less than 2 kilo., comes to the *hacienda*. Here it is screened to ¾ inch, the oversize passing through Cornish rolls, while the undersize is shoveled into bins. These are built of stone; they are brick-lined at the opening, whence the ore falls into cars that take it to Chilean mills. The oversize, after passing through the rolls, goes through a trommel (2 ft. diam. and 3 ft. long) with half-inch openings, the oversize going back to the rolls while the undersize falls to the ground, to be shoveled into cars, in which it is taken to bins above the Chilean mills and subsequently fed into them by shovel. There are 14 Chilean mills; the die ring (5 ft. inner diam., 6 ft. outer) and shells are composed of Siemens & Martin steel, made in Germany. The die lasts one year, the shells twice as long. There is an iron ring inside the steel shell. Each mill (inside diam. 1.85 m.) has six openings, guarded by 60-mesh screen, all on one side. The discharge passes into a vat, whence it is raised by a centrifugal pump to distributors above the 14 concentrators. This is a vanner—with belt 1.8 metres wide—known as the Johnston table and manufactured by the Risdon Iron Works, San Francisco. It does good work, the belt being heavy so as to give it the motion of a *batea* instead of being simply sup-

is hard; he scoops the slime along, to the accompaniment of much splashing and the encouraging shouts of the driver who controls the operation. Openings, at various points along the canal, serve to distribute the slime to separate rectangular stone-paved spaces, where the chemical work is done. Each rectangle, 25 by 30 metres, is delimited by two timbers—4½ by 8 in., placed one over the other so as to make a wall 16 in. high. The *torta* which they enclose is 30 cm. thick.

The slime or *tama* is allowed to thicken, by loss of moisture through evaporation. Then comes the addi-

tion of the first chemical, common salt, which is thrown over the charge like a shower of hail. The salt is obtained from the lagoons near Zacatecas and is added in the proportion of 6 to 7% of the weight of the ore. This is an excess, but it is found to accelerate action and to diminish the consumption of mercury. After this part of the process, called *ensalmarar*, the mixing or *repaso* begins. This is done by the trampling of horses. One man, himself on horseback, drives 12 horses, four in a row, tied by the neck to each other. The crackling of the whip, the slushy tramp of the horses, and the shouts of the driver give animation to the scene. This goes on by day only, from 7 in the morning until 2 o'clock in the afternoon. After the day's labor, the horses are driven through a big tank to be cleansed, when more shouting and splashing enlivens the *hacienda*. This mixing continues for 24 to 30 days. Each afternoon every portion of the *torta* is turned over with shovels in the hands of 12 to 15 men. After the first three days comes the addition of copper sulphate (bluestone) followed by further mixing and then the mercury is introduced. The 'bluestone' comes from the United States; it is added to the *torta* in the proportion of 0.4 to 0.6% of the weight of the ore. In looking over a *patio* in which the charges are in various stages of treatment, some just salted, others just showered with copper sulphate, the contrasts between the rectangular patches of white and blue leaves a vivid impression. The mercury is added in the ratio of eight to ten times the amount of silver estimated to be in the charge undergoing treatment. It is carried in a cloth, folded like a bag, and swung freely, so that the mercury squeezes through in the form of small globules. This is done to ensure thorough assimilation; the operation being appropriately termed *incorporación*. Five or six men perform this work, on the fourth day. At the end of the process (after 24 to 30 days, as determined by test) more mercury is added, in the proportion of 5 kilo. mercury for each kilogram of silver present in the charge, making about 2,500 kilo. to each *torta*, this being introduced for the purpose of collecting the amalgam already formed. This operation is termed the *baño*. During the continuance of the treatment the *torta* is tested by panning samples in clay saucers, 6 in. diam., called *jarreros*. The operator pans the stuff down to a button of mercury and squeezes it between the thumb and index finger, to test its consistence, a flat bit of amalgam remaining, of a size indicating the extent to which amalgamation has proceeded. The rejected sand from this panning undergoes the ordinary fire-assay; when there is no further decrease in the content of this tailing, complete extraction is indicated and mixing in the *patio* ceases.

Then the horse with the scraper (*camon*) is employed to move the charge forward to a sump or *lavadero*, the *patio* being finally swept clean by 12 to 16 *peones* with brooms; the mercury can be seen in small pools and is splashed about during the manipulation required for this clean-up. The charge is moved to a sump or basin (*cajon*), 8 by 10 ft., where seven men, standing in water just over their knees, stamp around, and stir the stuff, while clean water is being added and fresh material is being fed from the *patio*. The top of the sump is on the same level as the *patio*; the bottom is six feet below the level of it and is enclosed in masonry, except on the lower or outlet side, where there is a barrier made of two boards that are perforated with 3-in. holes, twelve of them, in clusters of six each. The amalgam and mercury collect at the bottom, while the overflow drops into large cast-iron hemispherical basins (*apuros*), of 2½ ft. diam., which serve as traps. There are five of these, distributed along the exit-slucie below the sump. From the last *apuro*, the pulp flows over two parallel sluices

with riffles, and in this 12 to 16 boys, 8 to 9 years old, stamp around to aid the separation and arrest of any escaping amalgam. These little fellows, chocolate colored, with big straw hats and thin bare legs, are kept on the move, so as to stir the slime; they wade around at the bottom of a canal 10 to 12 ft. below the level of the *patio*. They receive 37 *centavos*, or about 20 cents U. S., per day. Most of the amalgam is caught in the sump and in the first two *apuros* at the head of the sluices. This clean-up occupies 16 to 17 hours. Finally, the rich deposit at the bottom of the sump is washed, one of the boards of the lower barrier being removed, while fresh water is turned in. What amalgam gets out of the sump, lodges in the first (and biggest) *apuro*. At the very end of the operation more water is added; the *peones* use scrub brooms and sweep the bottom clean. The amalgam and mercury make a big showing; they are lifted in iron ladles; these are the flasks in which the quicksilver is bought, their tops being cut off, and an iron handle inserted. From 1,500 to 2,000 kilo. amalgam is obtained from the clean-up of a single *torta*.

Six hundred horses are used in the *patio*; they last four or five years, if young; the older ones last only six months. They become poisoned by the copper sulphate; hence the washing each day. Some of the horses are found to gather a lump of amalgam in their stomachs, as much as half a kilogram, say, one pound. This used to be removed when the horse died, but now the Government claims the deceased animal, without permitting dissection, and it goes to the crematory. What happens to the silver amalgam is not stated.

The extraction is 80 to 85%, the tailing (*jales*) containing 100 to 150 g. silver, say 3 to 5 oz. per ton. The gold is caught in the concentrate on the vanners; practically none of it is saved on the *patio*. Nevertheless, down the creek there are two plants that re-work the tailing from the *hacienda*. To anyone accustomed to stamp-milling, it is surprising how the mercury is splashed around. The pavement of the *patio* itself must absorb some of it, for this pavement is made of slabs; these are irregular in size but usually 1 by 1½ ft., of of volcanic stone, a basalt called *recinto*.

In another part of the *hacienda* one can observe the working of a mechanical mixing machine, designed to be a labor-saving modification of the *patio* process itself. In a rectangle, 20 m. wide and 75 m. long, a plough, with eight blades, moving sideways, travels up and down. It is operated through a ratchet gear by a man who sits on the machine, as it is pulled by an endless cable of one-half inch diameter. This treatment requires 45 days and gives the same extraction as the ordinary *patio*. The superintendent prefers the old-fashioned horse method because it requires less time. It can be said truly that the trampling of the animals affords a better aeration of the charge than the mechanical plough, which appears to go through the sludge rather than turn it over. There should be more turning of the furrow.

Mechanical devices in place of animals were tried long ago and they have been used in different parts of Mexico, especially Sonora. In M. C. Roswag's 'Metallurgie de l'Argent,' there are descriptions of such substitutes, which in English are called 'kneading' machines and in Spanish *repasadoras*.

Other observations are permissible. The small boys who tramp about in the tail-slucie give their toes as riffles to assist the settling of escaping particles of amalgam. The stirring in the clean-up sump as done by seven grown men has its humorous feature, but it is effective. The method of moving slime onto the *patio* by the *camonero* is an absurdity at first sight, but it obviates a costly conveyor, and both horses and men are cheap at Pachuca. The Chilean mill affords better grinding than

the pounding action of the stamp, although it seems strange to see the *peones* shoveling into the mills and then taking a rest, when a mechanical feeder would do it so nicely. The temporary canals made between the *torta* and the sump, to confine the passage of the pulp, are kept tight with manure, the droppings of the animals in

the *patio*, thus contributing smells to the sights, a combination not uncommon in Mexico. There is a striking contrast between the modern vanning tables and the *patio* itself, the whole picture exhibiting a sublime disregard of all modern mechanical ingenuity as applied to the handling of material.

Ventilation at Bendigo.

With a view to improving the underground working conditions of the mines at Bendigo, the following suggestions were adopted at a conference of the mine-owners, mine-managers, and representatives of the Miners' Association:

(1) That close timber should be placed in all shafts and divisions of shafts where there are connections with adjoining mines to the bottoms of shafts; (2) that all shafts sunk deeper than this stage should have four compartments; (3) that all levels not in work should have doors at the shaft to shut off the air current if necessary; (4) that doors be put in the down-cast divisions of shafts, except at the bottom division; (5) that all ladder compartments be left fully open at and above the surface; (6) that the exhaust of air-winchies be turned into the sink-

El Camonero.

ing-compartments of the shafts; (7) that either air or water jets and pipes be put into raises and dead ends of cross-cuts and levels; (8) that cages and trucks should not be left hanging in shafts or at the mouths of shafts, when work is discontinued, thereby practically stopping all ventilation until work is resumed; (9) that in future sinking, if there is no fourth compartment, it should be mandatory to have a chimney constructed behind the shaft timber before the penthouse and cistern are put in position. It was further decided to ask

the Government to install a Root's blower in one of the deepest mines for experimental purposes and to give the same a fair and satisfactory trial of not less than six months, all costs and supervision to be provided by the Government. These steps are due to recent investigation made by Dr. Summons.

Copper Mining in Cuba.

Written for the MINING AND SCIENTIFIC PRESS
by BENJ. B. LAWRENCE.

Cuba has had, in the past, one copper mine worthy of the name—El Cobre, in the Province of Santiago, on the extreme eastern end of the island. The history of this property is well known to those conversant with the literature of copper. Fifty years ago it was famous as a producer of copper ore, which was shipped to England and to Baltimore. It has a record of production which has been variously estimated at between twenty and thirty millions of dollars, and its extensive workings give evidence of a large output. About three years ago an American corporation was organized for the purpose of freeing this famous mine from water. Owing to many difficulties, due largely to the fact that the old workings were badly caved, the efforts to recover the lower workings, which were at a depth of 1,200 ft., failed, and the property was once more allowed to be flooded. Sufficient work had been done, however, to show that substantial bodies of copper ore had been extracted from a mineralized zone comprising three or four veins running parallel for a distance of at least 5,000 ft. laterally, and actually worked to a depth of 1,200 ft. About \$800,000 worth of copper ore was shipped to the United States from the old workings of this property before they were abandoned. The veins, averaging seven feet in width, occur in an andesite, brecciated. Many old stopes were found 20 and 30 ft. in width.

The ore extracted from the surface workings was for the most part oxidized and rich in chalcocite. At a depth of about 50 to 60 ft. the oxides were replaced by chalcopyrite accompanied by iron pyrite in a silicious gangue. The sulphides showed an average content of 6% copper. The ore contained neither silver nor gold in paying quantity.

The hills adjacent to Cobre give evidence of the existence of other veins, which are now being prospected with a view to opening up virgin territory on this property. On the extreme western end of the island, in the Province of Pinar del Rio, there are substantial gossan outcrops from 150 to 200 ft. wide. Under this, at a depth of 40 to 50 ft., iron pyrite containing black copper occurs. These deposits promise to be extensive, and in some respects resemble the ore occurrence at Ducktown. In the Province of Santa Clara there are several copper showings of sufficient merit to invite the attention of the miner. This might also be said of other locations in Cuba yet unexplored. The iron and manganese mines of the island are being developed by several American companies.

It seems quite evident that the mineral resources of Cuba have not been systematically explored; especially is this true of the mountains back from the coast, where, owing to unsettled conditions in the past, but little work has been done. It has been the belief of a number of engineers that Cuba presents opportunities for intelligent prospecting, and it is much to be deplored that the Cubans have failed at this time to maintain a stable government on the island, when its resources were beginning to attract the attention of capital.

It is quite evident that if its mineral is to be developed at all, Uncle Sam must step in and take a hand in straightening things out. Many Americans living in Cuba since the Spanish war seem to be of the opinion that until the United States takes control of the situation no substantial advance can be made in placing Cuba where it should be—a producer of copper and iron ore. In justice to the administration of President Palma, it may be said that Americans have received every encouragement from the Cuban Government; they have met

with uniform courtesy; they have been protected in their rights, and have enjoyed peaceful possession of their property.

THE CONTRAST BETWEEN crystals on the one side and animals and plants on the other is obvious. There is with the former no change or development, neither progress nor degeneration, no survival of the fittest, no variation of character. Crystals are perfect and complete, each in itself. No struggle for existence takes place in the mineral world as it does among the individuals of the animal and vegetable kingdoms. It may be said that this is natural because no individuality obtains in the mineral kingdom, and hence it is absurd to look for any development among rocks and stones. But is this so? Individuals exist in the mineral kingdom just as they exist among animals and plants. Each crystal is an individual capable of growth by itself and independent of its fellows; each pursues its own existence. It is even in a sense capable of multiplication, for if a crystal be broken, each half can grow to a perfect individual, resembling the parent. Super-saturated solutions will immediately produce myriads of crystals from the parentage of one crystal fragment.

Mutilate a growing crystal by breaking its corners and edges, and it will heal itself and form a perfect crystal, asserting its individuality more persistently than many a living organism. If the definition of life be based on individuality, as some philosophers say, it will be difficult to exclude crystals. On further pursuing this comparison between the inorganic and organic world we are led to irreconcilable differences. In the organic world there is an unceasing change, involving progress or degeneration. The beauty, the form, and the character of living things is due to the continuous interaction with the forces of nature. Minerals remain constant and complete. There is no change, no response to external stimulus, no adaptation to environment. The only change is destruction and loss of individuality. True it is that a crystal of pyrite will change to limonite, but here the individuality is lost and destroyed and a new one produced. There is no change, no progress of the individual.

The symmetry of living things is obviously due to their environment or to their movement. But in the crystals it is inherent, essential. It belongs to the mineral independently of external forces. When we pass from the crystal to other inanimate objects, this is no longer the case. The form of a mountain depends partly on the nature of the rock of which it is formed and partly on the action of the water, the wind, and the weather to which it is exposed. The durability or weakness of the granite or shale contribute to the curve of the coast line and the contour of the cliffs, but the rise and fall of the tide, the prevailing winds and currents, each show their influence by indelible marks. Thus we find in crystals none of the essentials of living organisms, progress or degeneration, evolution, and influence of environment, but a constant, immutable individuality, a symmetry essential and inherent. It is the homogeneity of crystals that widens the chasm between animate and inanimate objects, for nowhere do we find this remarkable similarity of parts in any living organism. In the beauty of the organic world it is possible to imagine both an origin and a purpose; the origin may be conceivably sought in utility. They may have become useful because they are beautiful or it may be that they appear beautiful because they are useful. But in the mineral world it is different: These wonderful spars and gems have an infinite variety of form and color, they possess an intricate grouping of silky fibres and pearly flakes. What is the origin and what the object of all this beauty? What purpose does it serve in the economy of nature?—D. F. C.

The Iron Ore of Shasta County, California.

Written for the MINING AND SCIENTIFIC PRESS
By DONALD F. CAMPBELL.

The occurrence of extensive deposits of iron ore in the Shasta county copper belt is both interesting and important. Not only is there an enormous tonnage of low-grade iron ore occurring as a gossan, capping the great sulphide lenses, which form the copper deposits, but also there occur masses of magnetite of remarkable purity. These are sometimes intimately associated with the copper deposits, especially at the southern end of the belt and they also occur in the less productive part of the district.

The gossan cap of the copper mines carries 50 to 55% iron, and gold and silver varying from traces to about \$40. The distribution of the precious metals seems to be erratic and no generalization can be made, though high values in silver ore are often found immediately

its way, one looks down on the McCloud river and across a series of volcanics of varying ages and acidity. These find expression in characteristic smooth but steep hills, while at the back, the towering masses of sedimentaries form a rocky setting of gray crags and rugged pinnacles, framing one of the most beautiful river scenes in northern California. The tongue of diorite, east of the meeting of the waters of the Pit and McCloud rivers, is traversed by lenses of iron ore increasing in size and frequency as the limestone contact is approached. The diorite is characterized by quartz and augite, the latter being probably the source of much of the iron. In some cases these lenses reach a width of about 50 ft., but the country is undeveloped and the brush makes any detailed investigation a matter of the greatest difficulty. Traces of pyrite occur and one of the best exposures is to be seen in a short tunnel near the top of the 'hog back.' The origin of the deposits is interesting and is proved by specimens

Map of Portion of Shasta County, California.

above the sulphides. This ore is of a light and porous nature and is often traversed by veinlets of secondary quartz.

These deposits are the result of oxidation of the sulphide orebodies, which have been formed by replacement of the country rock by sulphides. Evidence of this is found in the occurrence of primary quartz phenocrysts in the gossan that can be readily distinguished from the veinlets of silica of secondary origin. In contrast to these gossan masses there occur bodies of heavy massive hematite and magnetite. The hematite has a characteristic black appearance and is often mistaken for magnetite. The origin of the deposits at the southern end of the belt is obscure, but it is interesting to note that traces of oxidized copper and zinc ores such as calamine, cuprite, and malachite have been found, though no sulphide is known to underlie these heavy iron ores. Their massive structure and compact nature suggest that pyrrhotite may have been the original mineral.

The saddle lying between the Pit and McCloud rivers near Baird is a mass of highly metamorphosed diorite carrying important deposits of iron ore. The geology of the district is complex. On crossing the divide, over which the steep and crooked road from the ferry wends

which can be found in all stages of alteration. Pyrite and a pyroxene, probably hedenbergite, gradually pass into limonite, and the latter preserves the fibrous structure of the pyroxene or the form of pyrite. The composition of the masses of iron ore is as follows: Iron, 68.5; P, 0.01; Si, 1.06; Mn, 0.37; S, 0.009 per cent.

The minerals associated with these deposits are typical of such a metamorphic area. Garnet and idocrase occur in quantity associated with hedenbergite of secondary origin.

Such a wholly undeveloped district, full of evidences of intense metamorphism, adjoining limestone known to contain deposits of oxidized copper ore, suggests the possibility of cupriferous sulphides in depth and there is an element of promise that pyrrhotite, with nickel or cobalt, might be found. It is satisfactory to note that these deposits are at last receiving some attention from the industrial world and that experimental works are being erected to test the feasibility of treating these ores by the Heroult process. These experiments should win the attention not only of local speculators, but of everyone interested in this process recently described by Dr. Haanel as a commercial success, for therein may depend the future of an iron smelting industry on the Pacific Coast.

Moss Copper on Matte.

Written for the MINING AND SCIENTIFIC PRESS
By CHARLES S. PALMER.

The formation of common moss copper on certain kinds of matte is too common a fact to need any description, but the beautiful deposit, which can be found in every assayer's cabinet, is itself an illustration both of the neglect that many interesting freaks of nature may suffer in the face of the sternly practical, and also of the very latest application of theory to practice.

Some years ago, when in charge of the chemical laboratory of the Washoe smelter at Anaconda, Mont., I had an opportunity to collect many of the by-products of the regular process of reduction. The mattes were a never-ending object of wonder. Some of the old furnace-men seemed to regard the appearance of some moss copper on the surface of a matte as an evidence of its high-grade character; others regarded it as an accident, indicating merely that the matte in question was not of the lowest grade. In my observation, the best grades of 'white metal' show comparatively little moss copper, yet I have never seen a piece as large as one's fist that would not show moss copper somewhere about it, especially in or near a cavity. This is more easily seen with an ordinary pocket lens.

In my study of mattes—I shall use the term in its widest meaning—I found many curious facts, one of which I wish to record here; partly wishing that other chemists may substantiate, or enlarge upon, my observations, and partly with the hope that some metallurgist, with a laboratory and suitable apparatus, may subject my work-day discovery to the careful test that it deserves.

One great advantage that I had at Anaconda was the friendship of the chief sampler, who kindly kept me informed of any changes or alteration in the great plant that would be apt to furnish new specimens for the student; and one day, when Mr. Thomas told me of the wrecking of two of the old reverberatories, in place of which one large long reverberatory was to be built, I took the first available chance to leave the laboratory for a half-hour and watch the work of digging away the old furnace-bed. At the reverberatory building, the foreman, Captain Kelley, gave me every opportunity, which I enthusiastically accepted; in fact, almost too enthusiastically, for the furnace-bed, in places, was a mass of matte still hot, and in my eagerness to get some particularly fine specimens I burnt some fingers which had become used to the ordinary burns—and here is the whole point of this discovery.

The matte in question was a beautiful dark bluish-purple, much like some of the finer grades of native bornite, only there was no varying nor iridescence in the color; it was one comparatively uniform dark bluish-purple. I took the samples out of doors where the light was better and studied them with some care, for this was the first time that I had secured such fresh samples of this kind of matte. While I was studying the samples, I noticed that there was but little moss copper showing on the surface. I was particularly careful to note this point, because I was at that time trying to establish some sort of a relation between the quantity and quality of the moss copper with the particular grade of matte.

I took the samples—the pieces were not large—up to my room and laid them on my desk. They were still so hot that it was necessary to lay them on several pieces of thick paper to keep them from burning the wood of the desk. I turned to some reports which were waiting and in fifteen or twenty minutes later I looked again at the mattes. I at once noticed two remarkable things: First, they had changed their color; second, they were still hot, when ordinarily samples of this size would have

cooled down so that they could be easily handled in the fingers.

Under the lens, the change in color was at once explained. The change in tint to the naked eye, was from a dark bluish-purple to a brighter reddish-purple. The lens showed that the new tint was due to the blending of the bright red of newly deposited moss copper with the old color of the general surface, the dark bluish-purple. The fact was interesting, for I had the good fortune to catch the matte in the very act of sweating out some moss copper, an operation that I had previously supposed must take place at a much higher temperature than would allow of direct observation. There was no mistaking the fact of the change in color, and the cause of it, namely, the sweating out of the moss copper, largely since the samples had been handed to me. I may add that, when I had visited the bed of the old furnace, the workmen were still playing water over it, and the steam was being formed in clouds; indeed so violently that at the time, I was warned that I would be burned. Fortunately, I was sufficiently enthusiastic to run the chance of being burnt, for I caught the matte in the critical stage.

So much for the change in color, and the attendant sweating out of moss copper. But what of the long continued staying at a comparatively high temperature? That was also a fact, the significance of which did not at once occur to me. However, on a little reflection, the explanation was simple and clear. It was a case of 'solid solution,' of the new physical chemistry, exemplified by a happening in daily life. Let me illustrate. This particular matte had dissolved a large quantity of copper; more in fact than it could hold in molecular proportions with the iron and sulphur, and for the particular compounds which would be most stable at the temperature of solidification, and which therefore would be just the ones that must be formed. Disregarding other ingredients, the copper was largely in excess; each molecule would even off its molecular peck or half-bushel, just as we have seen an old miller do with the half-bushel of the old mill, where he would draw a smooth stick across the top of the measure, scraping off the excess. In some similar way—not to press the metaphor too far—each molecule of the matte measures itself off; the excess copper is pushed out, and, note it well, with some little evolution of latent heat. The many small fragments of excess copper fall together (by 'accretion'), and are extruded from every available surface. This tendency of the copper to find its way to the surface is evidence of a considerable pressure in the inside of the mass of matte.

The query comes up: Why can all this happen when the matte is practically solid? This is easily answered. A moment's reflection will remind us that, in an exact sense, there is no such thing as an ideal solid. What we call solids are only very tough and viscous liquids. Given pressure enough, and time enough, and one could press any solid to any shape, provided that one could find the machine capable of exerting the necessary pressure. Fortunately, we have one in the cooling matte. Moissan, the great French chemist, found another in the cooling mass of cast iron or steel, when he made diamonds artificially.

But there are two or three other points about this observation that may be easily illustrated. The latent heat given off by the 'solid solution' of the excess copper in the matte, is illustrated in the old experiment that we used to try when we were boys; the one where we made a supersaturated solution of Glauber's salt (sodium sulphate). On cooling this in a quiet place, it would reach the temperature of the ordinary living-room without letting any of the dissolved Glauber's salt separate; but, when we opened the mouth of the closed flask in

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

Where the claimants sued in an action for trespass on the extra lateral dip of a vein having its apex within the claimants' location, it was held that the claimants were not bound to establish the identity of the vein by the actual tracing thereof from within the surface lines of their location to the point of the alleged trespass, but that the claimants were only bound to show the continuity of the vein between the apex within the lines and the point at which the alleged trespasser was mining.—*Daggett v. Yreka Min. & Co., (Cal.) 86 Pac. 968.*

In the location of mines prior to 1884 it was held that there must have been the discovery of a vein, and marking of a location so that its surface boundaries could be readily traced and the end lines of the surface location must have been laid off parallel to each other and at right angles to the vein.—*Daggett v. Yreka Min. & Co., (Cal.) 86 Pac. 968.*

Prior to the present mining laws there was no statute requiring, authorizing, or giving any definite legal effect to the posting and recording of notices or location. It resulted that the posting and recording of such notices did not in themselves constitute a location, but that they must be held to be acts which tended to show a proper marking of the surface locations, so that the boundaries of the claim could be readily traced.—*Daggett v. Yreka Min. & Co., (Cal.) 86 Pac. 968.*

In an action for damages and for trespass for taking ore from the plaintiff's mines it was held that the plaintiff could prove that the defendant had taken ore within the plaintiff's extra lateral rights without alleging the existence of the vein having its apex within the surface boundaries, but departing from over side lines on its downward course or that the end lines were parallel.—*Daggett v. Yreka Min. & Co., (Cal.) 86 Pac. 968.*

In an action to settle conflicting rights in a mining claim, it was held competent for the parties to agree that the only point to be contested was whether the complainant under his location resumed work on his claim, after forfeiture and before defendant's location.—*Gibberson v. Wilson, (Ark.) 96 S. W. 137.*

A person having an option to purchase a mine, assigned a half interest to others, in consideration that they would pay certain installments of the purchase price. The parties then formed a mining partnership to purchase and work the mine. Afterward the complainant, one of the purchasers of the option, paid the first installment, and when the second became due the purchasers all gave their joint note to one of the original vendors, and borrowed money on another joint note and paid the other vendor, it was held that though the complainant had not paid his share of the two notes, his failure to do so did not forfeit his interest in the mine.—*Larsh v. Boyle, (Colo.) 86 Pac. Rep. 1000.*

The rights of an adverse claimant to the premises in controversy are limited to those existing at the time of filing his adverse, and he will not be heard to assert a right to the disputed premises by virtue of one brought into existence thereafter, as this would be permitting him to assert title by virtue of rights other than those upon which his adverse was based.

A location without a discovery carries with it no rights, and if no adverse is filed there can be no adverse suit. The alleged rights upon which an adverse is based must be established by the evidence.—*Healey v. Rupp, (Colo.) 86 Pac. 1015.*

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The rock from Columbia, Cal., marked W. G. C., is Diorite.

The mineral from La Plata, Colo., marked W. R. P., is Feldspar, not corundum.

The specimen marked R. A. K. from Central City, Colo., is Dacite or quartz-andesite.

The mineral from Los Angeles, marked F. G., is blue and white quartz coated with Limonite.

The gray flakes in the decomposed sulphide ore from Darwin, Cal., marked A. H., are scales of Talc.

Specimens from Mascota, Jalisco, Mex., marked P. F., are: No. 1 and 2. Quartz-porphyry, not copper bearing; No. 3. Rhyolite; No. 4. Chalcopryrite, tarnished.

Rocks from E. C. B., of Buffalo, N. Y., are: No. 1. Hornblende-gneiss; No. 2. Chloritic schist; No. 3. Hornblende-schist; No. 4. Chloritized gneiss; No. 5. Pyrrhotite; No. 6. Calcite with quartz and chlorite.

The rock from Yamhill, Oregon desert, marked R. B., is an altered volcanic rock, probably Rhyolite, and is similar to some of the Nevada rocks. The brown mineral is Limonite, apparently a pseudomorph after a platy mineral like biotite.

PRECIPITATION BY ZINC-DUST.—Precipitation by means of zinc-dust was formerly practised in the cyanide plant of the Wasp No. 2 Mining Co. at Yellow Creek, S. D. The precipitation was carried on in the sump-tanks. These vats for this purpose were provided at the bottom with a perforated circular iron pipe, connected with the air-pump. The bottoms of the vats were inclined $\frac{1}{2}$ in. per ft. toward the discharge pipe to insure complete drainage. When the vats had filled with gold-bearing solution the air was turned on, giving the solution a circular motion, with also ascending and descending currents. The air pressure used was 45 lb. per sq. in. Then zinc-dust was added in the form of an emulsion around the edge of the vat and the contents of the vat agitated by air for ten minutes. Then the material was pumped through the filter-press, leaving some of the zinc-dust and precipitate in the bottom. The amount of zinc-dust used, to start with, was one pound per ton of solution. This was gradually reduced to $\frac{1}{2}$ lb. for the strong solutions and $\frac{1}{4}$ lb. for the weak solutions in succeeding precipitations. It took two hours to pump 12 tons of solution (the amount usually precipitated) through the filter-press. The tailing solution from the filter-press usually had a value of about 10c. per ton, showing that the precipitation was good. The objections to the method arose in treating the precipitate taken from the presses. This usually packed very hard, so that it was difficult to disintegrate it for the acid treatment. It was found that the dilute sulphuric acid would attack the dust precipitate but very slightly, it being practically impossible to get the zinc out. This fact may be due to the coating of metallic gold on the zinc particles, protecting them from the acid. At the Golden Gate mill in Utah and in several other plants where the process is in use, a mixture of sulphuric and nitric acids is used, seemingly with success. Finally the acid treatment was discarded and the zinc precipitate was roasted and then smelted. The usual zinc-thread precipitation then replaced the zinc-dust method.—*Bulletin No. 5 South Dakota School of Mines.*

An African Conveyor System.

The cyanide process, whereby gold is primarily dissolved from its matrix of quartz, as found in lodes, consists of vats for chemically treating the whole mined product and means whereby the residuum is ejected after chemical separation of the gold. Where this process is carried on to the extent of hundreds of tons of material per day many vats of large dimensions are required, combined with conveying machinery whereby the raw material is not only taken to the vats, but the residuum of sand is also carried to waste places to accumulate in piles of great magnitude. This statement applies particularly to the goldfields of South Africa, where the cyanide process is much used, and especially to the largest known plant of its kind, namely, the recently built joint mill of the Knights Deep, Ltd. and Simmer & Jack East, Ltd. companies.

In the combining of these two plants much re-arrangement of old material and the addition of new conveyors were made necessary. The conveyors were furnished by the Jeffrey Mfg. Co., of Columbus, Ohio, and in no place has the belt-conveyor shown better its ability to handle gritty

vats. Having reached the top of the dump, the sand is delivered to the ninth conveyor of the same make as the incline conveyor, except that it is now but 125 ft. on centres and is built on a horizontal portable wood frame, thus making it possible—by the gradual shifting of this frame, in the extension of the conveyor head from the incline conveyor, besides the moving of it in an almost complete circle about the head of incline conveyor—to build gradually a plateau from the top of the original pile. As the work of moving this portable conveyor is too cumbersome a work to perform daily, there is placed at the head of this last conveyor what is known as a distributing boom of two 36-in. belt-conveyors, all self-contained within a portable steel frame. The first of these is merely a 30-ft. extension of the last conveyor, shown in the upper left-hand corner of the illustration, while the second conveyor of the boom on 56-ft. centres is placed in boom at right angles to and back of the advance belt. This last boom conveyor is on rollers in the steel frame, so that it can distribute material 56 ft. to either the right or left, being fed through a three-way hopper capable of placing material to advance belt or to right or left on cross-belt. In time it is intended to extend the ninth conveyor, feeding boom, from 125 to 450-ft. centres. Thus it can be seen that with the present dump-conveyor system, a plateau an eighth of a mile in diameter and 120 ft. high may be built before it will become necessary to change the present system.

Conveyor at the Knights' Deep Mine, Johannesburg.

and heavy material and for carrying it to a great distance. In the joint plant, a space 170 by 470 ft. is occupied by 40 vats, each 40 ft. diam. by 9 ft. deep, arranged in four rows of ten vats each, known as 'treatment tanks.' Over these are situated 16 similar vats known as 'collecting tanks,' which are placed concentric with 'treatment tanks' No. 4, 5, 6, and 7 of each row. Over the 'treatment tanks' and below the 'collecting tanks' there are four 20-in. rubber belt-conveyors, one over each row, driven by separate motors. These conveyors distribute the material from vats above to those below, as material is ready to be treated.

Beneath each of the four rows of treatment vats, and directly under the four conveyors above mentioned, there are four 20-in. rubber belt-conveyors each 426-ft. centres, running over three pulley troughing idlers, 4-ft. centres. These conveyors are fed with the residuum of sand and work through a small opening in the centre of the bottom of each vat; they carry the sand to one end of the rows of vats, delivering it to two cross-belt conveyors at right angles to ends of the first four conveyors. These cross-conveyors face each other, the first carrying the refuse from the first and second of the vat conveyors to the head of the third vat conveyors, while the second cross-conveyor takes the fourth vat conveyor material to the same point, thus concentrating all the refuse at one point. The refuse being thus collected from the treatment vats at one point and on one level, it is then delivered to a 30-in. rubber-belt conveyor, which, in carrying the refuse on 310-ft. centres, elevates it 20 ft. into a 50-h.p. motor-house at the head of the conveyor and at the edge of the dumping ground, as shown in the accompanying illustration.

At this point the material is delivered to the eighth and longest belt of the system, a 30-in. 6-ply $\frac{3}{16}$ -in. rubber-covered Century belt 430-ft. centres, which carries the refuse to the top of the dump, as shown in illustration, a difference of elevation of 122 ft. from the first four conveyors under the

long experience with the Chicago house of the company, is in charge.

THE COMPRESSED AIR MACHINERY Co., of San Francisco, reports that, notwithstanding the disaster of last April, it has manufactured and sold 22 air-compressors and 8 Word Bros. drill-sharpeners since completing its new shops.

THE HEWITT MACHINERY Co., 503 Monadnock Bdg., San Francisco, announces that it has been appointed representative of the Atlas Engine Works, of Indianapolis, Indiana, and carries a complete line of engines and boilers for hoisting and power service.

THE HUG WATER WHEEL Co. of Denver, recently shipped two 5-ft. double-nozzle water-wheels to the Basin Reduction Co., Basin, Mont.; one 6-ft. wheel to Utah; one small wheel to the Midas Mining Co. for the Penrose mine, Leadville, and one to the Pikes Peak railroad, at Colorado Springs.

Trade Treatises.

THE JOHN A. TRAYLOR M. Co. describes the Imperial ore screen in Bulletin E, which has been recently published.

THE B. V. STURTEVANT Co. has issued a pamphlet illustrating its steel pressure blowers in an interesting and instructive way.

The tenth edition of *Graphite as a Lubricant*, published by the Joseph Dixon Crucible Co., is a useful contribution on the subject of lubricants and gives trustworthy information on modern practice in graphite lubrication.

REAVELL Co., LTD., of Ipswich, has published a pamphlet on its patent air-compressors. These present many new features, consisting of four cylinders arranged radially in a circular casing. The compressor has no suction valves and is very convenient where portability or compactness are important

Editorial.

IT IS ANNOUNCED that the legislature of the Province of Ontario proposes to raise a direct revenue from the mining industry, by levying a royalty on the output. This is aimed chiefly at the Cobalt mining companies, now largely controlled by Americans. The proposal is likely to be opposed by the large financial interests involved and, if the legislature is like most bodies of the kind, persuasion is likely to prevail. The press of Ontario is insisting that the ores of the Province be smelted locally, so that the American reduction works shall not gather the profits of that operation. It is a short-sighted policy. If it pays to smelt the ore in Ontario, some one will do it. Attempts to regulate these questions by legislation are childish.

OUR London letter, as usual, is full of interest. This week there is an account of the big financial operations involved in the development of copper mines near Lake Tanganyika in central Africa. The enterprise is on an enormous scale, and the forecast of its energetic promoters is fully in keeping with the splendid optimism that has dared to lay the foundations of an important copper industry in a region only recently penetrated by civilized man. Among the engineers connected with the undertaking there is at least one who hails from our West, and for this reason, among others, we hope the expectations of these builders of empire may be reasonably fulfilled. Another portion of our London letter refers to the re-awakening in Cornwall, and it is fitting enough that one who has done such credit to the Cornish name and led the way so effectively in the development of Colorado, should be the spokesman for the 'old county.' Mr. Richard Pearce's observations will be appreciated by his numerous friends on this side.

MINING COMPANIES are often organized under the laws of States other than those in which they do their business and in this way, as permitting of the evasion of honorable obligation, the States of New Jersey, West Virginia, and the Territory of Arizona are particularly favored by promoters. In London they go to Guernsey, in the Channel Islands, in order to escape certain regulations of the Companies Acts. These practices are open to criticism from the point of good citizenship, but they are thrown in the shade by the recent departure of the Tanganyika Concessions Ltd. which has been registered under the laws of the Congo Free State. New Jersey is destined to take second place as a promoter's haven; when you want to dodge onerous obligations, register your company in the jungle. No wonder that *The Investor's Guardian* makes a protest. Is it that the King of the Belgians wants additional sources of revenue?

IN THESE DAYS even respectable newspapers flaunt full-page advertisements of mining stocks. To give an air of financial importance to this peddling of chances, it is the growing practice to employ the medium of Securities Corporations, Trust Companies, and Banks—many of them in capitals as large as their real capital is small. Mushroom mining camps nowadays boast financial institutions with imposing names, and it is easy to understand that the farmers in Iowa, the clerks at New York, and the cooks in Maine do not appreciate the fact that such high-sounding fiduciary organizations may be brokerage concerns and promotion syndicates of an ephemeral kind. There is a look of comic opera about many of the prospectuses advertised; some of this may develop into sordid tragedy, for it is obvious that untried prospects are being floated as mines on the strength of the wonderful riches of the new goldfields in Nevada. Our readers do not indulge in this form of gambling, they prefer the saner kind, where the deal is from the top of the pack; so we need not admonish them. But for the sake of decent mining, we hope they will keep as many of their friends as possible from throwing away their money. The opportunities for sane speculation in mining are numerous enough without indulging in a blind gamble.

Only recently the stock of the Bullfrog Rush Mining Company was offered on the basis that there was \$6,000-000 worth of ore blocked out. Shortly thereafter three of the gentlemen on the directorate resigned and published an advertisement, stating their reason for so doing, which was, that although the property is "a splendid prospect" it has been ascertained that "the best average assays obtained in the lower workings are from 60 cents to \$1 per ton." Underneath this advertisement appeared another from the trust company that had sold the stock, offering to take back the shares—and pay for them? Not at all, only permitting shareholders who had been misled by suppositious ore reserves to select from any of the company's "new promotions." We notice that the Governor of Nevada, just re-elected, is a director of this and other companies. It is a mistake for governors to figure on the prospectuses of stock companies; it leads to complications. They pledge the credit of the State to speculative enterprises concerning which their judgment is fallible. Governors are not necessarily good judges of mines.

Who Is a Mining Engineer?

This discussion is now closed. It has served its purpose. The question has been answered. It is true that one reader objected to the ventilation of the subject and spoke of it as a "miserable hollow discussion," and another in a more humorous mood sent a message across the continent, saying:

*"Il y a des hommes qui se font Espagnol
Qui ne sont pas de tout Espagnol"*

Which might be interpreted as meaning that there are 'false alarms' in every walk of life. However, we do not apologize for giving our columns to the debate. It has fulfilled a purpose, namely, to crystallize current notions. We recognize now that a mining engineer is

one who performs the duties of a mining engineer. What are those duties? Before defining them, it will be well to summarize the views expressed by our correspondents.

Among those who have contributed are scientific men, superintendents of mines, journalists, and investors. In a multitude of councilors there is wisdom. Let us give precedence to the scientific view; naturally, it begins with a precise definition. Mr. George J. Bancroft quotes the dictionary and says a mining engineer is one who is "skilled in the principles and practice of all the operations of mining." But if he does not apply those principles to actual operations, he remains only a possibility. He must demonstrate the possession of certain abilities. Therefore we agree with Mr. Walter E. Koch that, although a man may graduate from an engineering college, the passing of his examinations does not make him an engineer; emphatically, he must do things, he must have put his training into practice. This is in opposition to those who think, with Mr. Algernon Del Mar, that "a mining engineer is one who takes a diploma from an institution making a specialty of mine engineering." The mining engineer is essentially a worker; by his deeds you shall know him, and not by his credentials of instruction nor by scientific attainments that have yet to be put to the test. Such evidently is the view of that experienced employer of engineering talent whose identity is hidden under the signature of 'A London Investor.' To him the test is whether a man "does good honest work in the direction of mining enterprises," for whether he examines, manages, or plans the operations around a mine, his work is a contribution toward the "direction" of the enterprise. We agree with this contributor in deprecating the idea that mere titles indicate practical proficiency. The alphabetical appendage or the luminous tail has ceased to be impressive. A man who is a F. G. S., F. R. G. S., even A. I. M. E. or M. E., may be an inexperienced duffer or a tender fledgling, no more an engineer than a draughtsman is an architect.

It is pleasant to notice that many of the contributors, like Mr. G. C. Hewett and Mr. E. Rammelmeyer, acknowledge that the graduation certificate does not make men doctors, lawyers, or mining engineers. The days of their own apprenticeship are far enough behind to give them a broader outlook and to enable them to appreciate that "duty well done, with honesty of purpose" often characterizes men lacking an academic training. There is no "exclusive set." In America, the land of all others where professional men are granted complete freedom of opportunity, there are many who have risen to a distinguished position without college training. We number among our friends several in the foremost rank of the profession that never graduated from any college; they are men of fine judgment, wide experience, broad knowledge, and they are the first to confess that they regret to have missed the preliminary training—which they are giving their sons. Men may become skillful engineers without academic preparation, but it is quite certain that they achieve their fitness more laboriously, less directly, and much less frequently than if they had received the impetus of a special training in early youth.

So here's a hand to that type of American manhood, the mining engineer who has achieved efficiency despite every obstacle. All honor to him!

Some of the volunteers in the profession have paid their compliments to the regulars. Mr. George Huston, as a newspaper man, states that 90% of the failures in mining in his part of the world are due to college men. That is an unscientific statement; it is probable that 95% of the operations were directed by college men and, in any event, not 10% of the mines that start are ever successful. He inveighs against the globe-trotting fellow who, possessing a superficial knowledge of many places, undertakes to unravel the geological structure of a district almost at a glance. In this he is right; such quacks are extremely dangerous. They are not engineers, because they do not do things. They talk about them.

With some of our correspondents we cheerfully disagree; as, for instance, with those who consider that journalism is a good preparation for mining engineering. As a journalist himself, the writer does not hesitate to say that the describing of things, even the "sifting machine" of keen observation, does not make a man a mining engineer or go far toward preparing him for such an occupation. The fatal facility of the scribe is dangerous. So is the enthusiasm of the purely scientific mind. Scientists and journalists in mining are not engineers. They do not do things. They write about them, they forecast them, they explain them. They do not perform the duties of a mining engineer.

And thus we come to the letter of Mr. E. E. Wann, which we publish as representative of those who delight to jibe at the 'big guns,' the 'exclusive set,' the 'inner guild,' and so forth. It is all bunkum. So is the tiresome contrast between 'practical men' and 'college men' where 'practical' stands for the ignorant, lazy, or unsuccessful, and 'college men' for presumptuous boys, inexperienced youths, mere book-worms, enthusiasts from the library, and the like. It is experience and intelligence that count, mere experience—simply to have lived, seen, and suffered hard knocks—does not suffice, unless intelligent use has been made of it all. To anyone irritated by the success of the well-trained energetic men who dominate the profession, such a personage as Marcus Daly may possibly stand for a type of the mining engineer, but to no one else. He was a miner and mine operator, an enterprising ignorant man who was pitchforked by accident into a prominent position. As to comparing his "achievements" with that of a "mining engineer of the college type," these columns can be better employed. To the uneducated it may be a satisfaction to suppose that Daly "hired" those whose knowledge he lacked, but it is a fact that he had such abysmal ignorance as to say that he had no use for technical men. Herein he failed in his duty, for it is required of a mine manager that he shall employ all the appliances conducive to good work, and of these none is so effective as science. Yet we do not deny to Mr. Wann the right to label Marcus Daly a mining engineer; he was in charge of mines and he directed their operations, therefore he was a mining engineer—but a bad one. And so we agree heartily with Mr. William Magenau that the type of man we are trying to label

cannot be "a paragon of ability and rectitude"; there are mining engineers and mining engineers. All the efforts of institutes and professional associations have failed to pick the sheep from the goats. Such a criminal as Whitaker Wright was a member of the American Institute of Mining Engineers when he committed suicide, and today a member of the more exclusive Institution of Mining & Metallurgy is dodging extradition laws on the Riviera in consequence of flagrant wrong-doing in connection with a copper mine in California. The trouble is that a man may be a fit and proper sort of mining engineer in 1896 and wholly unfit for decent professional association in 1906. On the other hand, a fellow who falls by the wayside in 1896 may have pulled himself together and be a responsible man ten years later. The personal equation remains yet the great insoluble theorem in human mathematics.

Far different is the spirit of Mr. Edward W. Ralph's letter; as a journalist and a miner, he pleads for a chance to make good—for himself and for others who did not ride into the profession on a coach and four. He can thank his stars that he lives in a country where the only test is fitness, for whether he graduates from the stope or from the library, he will have an opportunity to learn mining engineering. It will be harder work and it will take longer than for the young man from the Columbia School of Mines, but earnest purpose will count. There is plenty of room for such men.

Thus, finally, we come to the question: What are the duties of a mining engineer? Mr. G. W. Miller says, properly enough, that his functions are often held to include requirements foreign to mining. Nor can he be intimately versed in all of them. The field has become so wide, that he must have a general knowledge, one or two specialties, and in addition he should possess that invaluable gift—good sense enough to know what he does not know. It is useless to expect walking encyclopedias to run mines or peripatetic reference libraries to superintend smelters. This much it is safe to say, that men who have never managed a mine are rarely qualified to examine them for purchase, that superintendents who have investigated several mines are more likely to direct their own operations well, that those who have passed through such subordinate positions as assayer, surveyor, and underground superintendent have received a good preparation to become general managers. But none of these are rules; men have a magnificent way of breaking precedent, especially in a land where supreme capacity need bow to no fetish. The obvious duties of a mining engineer are to superintend operations, to plan the work of a mine, to choose, erect, and apply machinery, to sample and examine properties in order to appraise them, *to make a mine out of a hole in the ground*. Therefore those who write about mines, those who talk about them, those who visit them, those who finance them, those who buy and sell them, those who speculate in them, are not mining engineers; and whenever a mining engineer ceases to perform the duties of his profession and devotes himself to those of the promoter, financier, speculator, journalist, or farmer, he ceases to be a mining engineer. He is a shoemaker who sticks to his last.

Special Correspondence.

Butte, Montana.

Scarcity of Labor.—Raise in Wages.—Increased Production and Enlarged Smelter Capacity.—Boston & Montana Working Rich Ore.—Favorable Developments in Depth in Amalgamated Mines.—Butte Coalition Preparing for Bigger Output.—Exploring the Alice Group.—Calumet & Belinda.—Clark's Mines in Poor Zone.—Butte Central Cuts New Lode.—General Activity.

The scarcity of labor in Butte has greatly retarded production of copper during the past few months, and the condition has been getting worse. It is expected that the increase of wages of underground men from \$3.50 to \$3.75 per day, voluntarily made by all of the big companies, led by the Amalgamated, will assist in improving labor conditions. The increase means an added expenditure for wages on the part of the big companies of not less than \$1,000,000 per year. The daily output of the Butte district at present is about 13,500 tons of ore, but the quantity fluctuates very much. The Boston & Montana, one of the Amalgamated companies, is producing about 3,500 tons per day, and is planning to increase the amount by the first of December by 500 tons. The increased production will be shipped to the Washoe smelter at Anaconda for treatment, because the Great Falls smelter of the Boston & Montana is taxed to its utmost capacity at present, as it handles all of the Boston & Montana ore and some of the ore from the mines of the Butte Coalition Co. The 500 tons increase will come from the West Colusa mine, which has been shut down for some time while improvements were being made. With the completion of improvements at the Great Falls smelter, which are now under way, that plant will be able to handle 1,500 tons per day more than it is handling now, and the Boston & Montana Co. expects to contribute about 700 tons to that increased consumption. The smelter improvements will probably be completed in 6 to 10 months. The Boston & Montana is mining an unusually high grade of ore at present, the average yield of copper being about 5% for the first and second-class ore. The ore from the Leonard mine assays $5\frac{1}{2}$ to 6%. The bottom levels of all the mines are looking better than ever. The company is mining from five shafts—the Leonard, Mountain View, West Colusa, East Colusa, and Pennsylvania—and is sinking two new shafts on the Greenleaf and Badger State. The Leonard shaft is 1,200 ft. deep, but there are workings below that point, from adjoining claims, and a raise is being made from a depth of 1,400 ft. to connect with the shaft. The Pennsylvania is 1,845 ft. deep, the West Colusa 1,600, the East Colusa 900, the Mountain View 1,800, and the Greenleaf 550. Work on the Badger State shaft has just begun and the shaft will be made 2,000 ft. deep.

Other Amalgamated companies are as active as the Boston & Montana, and a great amount of development work is being done. The deeper the mines are opened the bigger the veins are found. So far the deepest point from which ore is extracted in the Butte district is 2,400 ft. The shafts of the High Ore and the Never Sweat, both Anaconda mines, are more than 2,500 ft. deep, but the veins have not been cross-cut below the 2,400-ft. level. Sinking is going on in both shafts and no cross-cutting will be done until 2,600 ft. is reached. The Anaconda Co. is mining from its mines about 3,600 tons of ore daily, and a semi-official statement is that the ore assays $4\frac{1}{2}$ % copper on an average. The shaft of the Anaconda mine is 2,450 ft. deep, and will also be sunk to a depth of 2,600 ft., but work on sinking has been stopped

while raises are being made from the 2,400 and 2,200 levels, and until the mine is ready to handle the water in the shaft and that coming from the 2,400 cross-cut. The vein has been cut at 2,400 ft. and is as wide and fully as rich there as it is on the 2,200, carrying a big quantity of copper glance. The cross-cut is being continued southward and has reached a distance of about 2,000 ft. from the shaft. It is understood that this cross-cut will connect with the Belmont shaft, in the southern part of the city, and that the Belmont will ultimately be made the main working shaft for the Anaconda mine.

The mines of the Butte Coalition Co. are being put in condition for a big production, and it is predicted that within a year the Coalition will be hoisting 3,000 to 4,000 tons of ore per day. When the new company took over the mines from the United Copper they were in a bad condition, showing evidence of the fact that during the last few months of possession by that company the mines were worked with the evident object of getting out as much first-class ore as possible before the properties were turned over to the new owners. The necessity of getting the mines in proper order curtailed the production, and it fell from about 1,600 tons per day to 900, but has again been increased to 1,200 tons. In the opinion of mining men Butte Coalition will, within a year or 18 months, equal North Butte in production, average value of ore, and ore reserves. The company is beginning to reap the benefit of the liberal share it received in the division of the orebodies that were in dispute between the United Copper and Amalgamated companies. Mining has been resumed on a vein, known as No. 3 of the Pennsylvania, but lying south of that property and under a number of city lots, and the richest copper glance mined in the Butte district is being hoisted from it. There is from three to five feet of ore that assays from 60 to 90% copper, and the remainder of the vein, about 9 to 10 ft., averages 10%. The vein is being mined on the 900, 1,000, and 1,400-ft. levels, and is being opened to a depth of 1,800 ft. The Boston & Montana, under the terms of division, gets 62% of the value of the ore mined from the vein, and the Coalition gets 38. The Boston & Montana Co. has run a drift from its 1,400-ft. level of the Leonard into the Minnie Healey of the Butte Coalition and opened a fine body of ore there. In cleaning up the Rarus and exploring that property several big orebodies were opened. The Corra, which was another property that was mined only for ore for several months before Coalition got possession of it, has also been developed into a good mine again. The Butte Coalition also owns the Alice group of mines, which is expected to become one of the most important assets of the Coalition.

La France Copper Co., owned by United Copper, has succeeded in unwatering the Lexington mines, and, in doing it, also unwatered the Alice mines above the 650-ft. point, where the workings of the two properties are connected by a cross-cut. The company will immediately begin work on the lower levels of the mine and expects to increase the daily output to about 400 tons within a few weeks. The output at present is 150 to 200 tons. The Lexington ore assays high in silver and also carries good copper values.

The shafts of the Calumet and Belinda of the Butte & Bacorn Co. have reached a depth of 500 ft. and cross-cuts will be run to the veins as soon as stations are cut. The shaft of the Colleen Bawn is but 330 ft. deep, the work on that shaft having been slow owing to bad ground. A cross-cut north and south will also be run from the 300-ft. point. There is a vein within 100 ft. of the shaft.

The mines of the Original Mining Co. owned by W. A. Clark, have entered the lean zone in which the Anaconda spent so much unprofitable time and through

which the Parrot is now working. The Clark ore now being shipped is very low grade. The output has also been curtailed by an extensive cave in the West Stewart mine, and for several weeks the company has been averaging less than 500 tons of ore daily. The Clark mines for a year or more have varied more than any other property in the Butte district in daily output of ore and monthly production of copper. The old rumor that the Amalgamated Co. is likely to absorb the Clark mines in Butte has been revived.

The Butte Central & Boston Copper corporation has cut into the south vein in the Ophir mine at a depth of 500 ft., but the heavy flow of water forced a suspension of operations and it will not be resumed for several days, or until the vein is drained. It was cut 270 ft. from the shaft, but the value of the vein will not be known until penetrated by the cross-cut. The company is driving on another vein at the 500-ft. level and some silver ore of good value is being taken out. Some bodies of high-grade silver-gold ore have been opened on the 200 and 300 levels. Some streaks assay as high as 500 oz. of silver and \$25 in gold per ton, and 7% copper, but such streaks are small. The company has received its new hoisting engine, which will shortly be placed in position. As soon as it is in running order, sinking will be resumed and continued to a depth of 1,000 ft. The country below will then be cross-cut, in the expectation of finding copper. There are three known veins in the ground, but it will be a long time before it will be determined whether they are valuable.

The Butte-New York Copper Co., which has practically succeeded the Butte-Milwaukee in the ownership of the Pollock group of mines by the purchase of a controlling stock interest in the latter, will sink a new shaft on its property. The company has so far very little to sustain the high valuation placed on its stock in New York, but its property is favorably located.

Leadville, Colorado.

The Yak Tunnel Adds an Electrical Equipment. — The Resurrection to be Resurrected. — The Adams Mill. — Down-Town Geology. — Important Discovery in the Crown Point. — Development in the Catawba. — The Golden Eagle Makes Large Shipments.

The Yak Tunnel Co. has the construction work on its new electric plant well under way. The plant is being erected near the portal of the adit, and will furnish lights for the city in compliance with a franchise recently granted. Contemporaneously with this demand come requests from various mining companies for power, as evidence of the popularity of electricity among Leadville operators. Many of the best managed properties in the district have either installed or contemplate the introduction of electric hoists. Over 60,000 ft. of transmission has been ordered by the Yak Co., and in addition to several electric hoists, the company has in continuous operation two electric diamond-drills for prospecting work. The Yak Co. has recently closed a deal with D. H. Moffat for several years' lease on the Resurrection property in Big Evans gulch, and it will ultimately extend the adit to that property. The Resurrection embraces a total of 160 acres, and has been long on the list of the camp's large producers of both high and low-grade ores, but the big influx of water caused the mine to close down until tunnel connections could be made.

Tunnel rights have been granted by the Sentry and Morning Glory mines to the Yak Co., and a lateral will be run at an early date.

The machinery on the Burdette property is to be removed to the St. Louis, and a substantial mill will be erected to treat the output from the St. Louis. — The

Adams mill, recently completed, is a substantial addition to the milling facilities of the camp. This plant includes two Blake crushers, six 5-ft. Huntingtons, 19 Wilfley and six Card concentrating tables. The Card tables treat the slime or finer product and the Wilfleys the coarse. Sizers of the ordinary cone type receive the pulp direct from the Huntingtons and classify the pulp into two products for the tables. Five-foot cones settle the slime and deliver a thick pulp to the slime-tables, there being one settler for each machine. — The lessees on the Elva Elma have lately completed the installation of a modern hoisting and compressor plant. Development work is being rapidly extended into virgin ground and, judging from past records of this mine, we may expect it soon again to enter the list of producers. — The French Mining Co., in the Holy Cross district, has its big cyanide mill in successful operation, and the extraction is reported by the management as being excellent.

The progress now being made by the Home Extension Co. in the way of drifts and diamond-drill work will add materially to our stock of knowledge of the down-town district. The evidence so far furnished goes to prove that the faulting disclosed by the Penrose shaft was of greater magnitude than anticipated, and that the throw of the strata is to the west. This means greater depth for shafts in the Home Extension Co. and adjacent properties before they reach the ore horizon.

The Gem Mining Co., organized to prospect the old Crown Point and adjacent properties on Rock Hill, has opened what appears at this writing to be a body of iron-

A Part of Colorado.

silver ore 30 ft. thick and of unknown length. At last this company has been rewarded for more than two years' extensive development work. They have reached the extension of the ore-shoots worked in former times to the southwest. This part of Rock Hill has been one of the most productive in the Leadville district. — The Catawba, on Canterbury hill, has opened up a shoot of ore and a trial shipment is being made. Much interest is being manifested in this discovery, because of its magnitude, and as it is the first property to receive substantial development on this hill. — The Golden Eagle property is rapidly improving. During the last two months it has shipped from 11,000 to 14,000 tons of ore, which the management reports to be of an excellent grade. Recent developments have led to an arrangement with the Yak Tunnel Co., whereby a lateral will

be driven to the property to drain it and facilitate shipment of their ore.

The U. S. Circuit Court of Appeals has set aside the decree of the local court in the case of N. A. Munn, and others against the Ibex Mining Co., which owns the Little Johnny mine. In the Colorado court the plaintiffs were awarded \$193,448 damages, but this is now reversed by the higher court, the mining company being compelled to pay the costs only. The suit arose from the overlapping of claims located when the ground was first taken up in 1878 and 1879. The mine became highly productive about twelve years ago.

Salt Lake City, Utah.

Local Business.—Decision Against the Smelters.—Serious Position.—Possible Removal of Smelting Plants.—News From Bingham.—Tintic Dividends and Production.—Another Railroad.—Enlargement of Cactus Mill.—Important Discovery in the Daly-West Mine.

The ore and bullion settlements during the past week amounted to \$943,200, while during the same period there were sold on the floor of the Salt Lake Stock & Mining Exchange 360,523 shares of stocks for which \$312,061 was paid.

The smelter situation as it applies to the Salt Lake valley is serious at the present time, yet the business interests of Salt Lake are inclined to look at the future optimistically. However, the chances are very much against a continuance of the smelting industry on the site of the present plants. The injunction granted recently by Judge Marshall, of the Federal Court, against the American Smelting & Refining, United States Smelting, Bingham Con., and Utah Con., companies was a severe blow and the smelter managers almost to a man are inclined to the belief that Judge Marshall will be sustained in the Circuit Court of Appeals, where the smelter smoke cases are to be taken for final disposition. The court's decree is more sweeping than was first supposed for the reason that it restrains each of the defendants from operating their respective smelters with charges containing more than 10% sulphur as well as prohibiting them from running on ore or combination of ores containing arsenic. If the higher court concurs, it simply means that the defendants will be forced out of the business of smelting sulphide copper and lead ores; which would be the equivalent of ceasing business altogether, unless some process of roasting the ores were applied before being shipped to the smelter. However, that would be out of the question. It is more probable that new sites will be sought. The Utah Consolidated will probably build a plant somewhere within the Bingham district, where it can deliver its ore direct from the mine by aerial tramway. The Bingham Consolidated may go to a point near its Dalton & Lark mine in the lower part of Bingham; but what the United States Co. will do, can only be conjectured. The American Smelting & Refining Co. may have to abandon Murray altogether and centre its operations at Garfield, where the possibility of serious damage to growing vegetation is remote.—Two reverberatory furnaces have been blown in at the new Garfield smelter and the plant is now treating about 500 tons of ore per day.

The New England Gold & Copper Co., of Bingham, is working its mill with two shifts and turning out a high-grade concentrate to the amount of about 500 tons per month.—The Utah Development Co., owner of the New Red Wing mine, also at Bingham, is forwarding ore to a custom mill in camp, pending the construction of the plant of the Markham Gulch Milling Co.—Official announcement is still lacking, but there appears to be

little doubt about F. Augustus Heinze having closed a deal for the acquisition of a control of the stock of the Ohio Copper Co., at Bingham.

Shareholders of the Lower Mammoth Mining Co., operating in the Tintic district, have authorized a bond issue of \$40,000, the bonds to bear interest at the rate of 8% per annum, which are convertible into new stock of the company at the rate of \$1 per share within one year. With the new stock issued, the company will have a total capitalization of 190,000 shares. It is the intention to sink the shaft to the 1,700-ft. level and explore for ore-bodies known to exist at that depth.—Three Tintic mining companies have posted dividends for November, namely: Beck Tunnel Con., \$40,000; Grand Central, \$15,000; Victoria, \$10,000. Owing to having completed the purchase of more property, the Mammoth Mining Co. will pass this month's distribution. Shipments of ore to Salt Lake smelters from Tintic mines last week amounted to 138 carloads, the contributing mines and amounts being: Ajax, 4; Beck Tunnel Con., 9; Bullion Beck, 6; Carisa, 8; Centennial Eureka, 48; Eagle & Blue

Bell, 7; Eureka Hill, 2; Gemini, 7; Godiva, 2; Grand Central, 3; May Day, 3; Mammoth, 10; Scranton, 6; South Swansea, 1; Uncle Sam, 2; Victoria, 6; Yankee Con., 4; Tintic Iron, 9.—The Ajax Mining Co., of which Thomas Weir of Salt Lake is manager, has liquidated its indebtedness.

That the San Pedro, Los Angeles & Salt Lake Railroad Co. intends to reach Ely, Nevada, is evidenced by the fact that surveys have been completed to a point near Fish Springs in the Deep Creek mining district and a map of the proposed route has been filed in the Federal land-office. The road will leave the main line of the Salt Lake Route at Tintic Junction and go westward from that point. It is said that construction will begin within the next 60 days with a view to heading off the Western Pacific from entering this western Utah and eastern Nevada territory.—The organization of the McDonald Ely Copper Mining Co. has been perfected in Salt Lake with Thomas Kearns, David Kieth, and E. A. Wall as the principal shareholders. The basis is the Robust, Maceo, and McDonald groups of claims covering about 4,000 ft. of the characteristic mineral zone of the camp on the north side of Robinson cañon; also 1,300 acres of land

with water rights located about eight miles south of Ely, which has been acquired for mill and smelter-site purposes.

The Cactus mill of the Newhouse company in Beaver county is turning out about 100 tons of high-grade concentrate daily. The plant has been treating in the past from 600 to 800 tons of ore daily. New equipment is being installed to increase the capacity to 1,200 tons. Two electric hoists are being installed on the 600-ft. level, one of them to be used in sinking on the new orebody. The forty new cottages ordered by Mr. Samuel Newhouse are under construction.—By far the most important developments of the year in the Daly-West mine at Park City is the orebody disclosed on the 1,200-ft. level near the side-lines of the Daly Mining Co. The ore is high grade, running about 100 oz. silver and 20% lead. The vein is about 10 ft. wide; a raise has been run for 100 ft., while a second one has been started.—Jesse Knight, of Provo, has bought the property of the Mammoth Consolidated Mining Co., in the Snake Creek district. It will become an asset of the Mountain Lake Mining & Milling Company.

Toronto, Canada.

An Important Decision in the O'Brien Case.—News From Cobalt.—Scarcity of Labor.—Several Important Sales.—New Discoveries.—Another Vein in the Grace Mine.—Smelter Building Near North Bay.—The Laurentian to be Operated by Company.—Rush to Placers in Saskatchewan.—New Process.

An important decision has been made by the Ontario Government in the case of the O'Brien mines, a rich Cobalt property of some 140 acres, situated in the immediate neighborhood of the noted La Rose mine, and estimated as being worth at least \$10,000,000. For the last seventeen months it has been in litigation, the Provincial Attorney General having brought an action against the syndicate controlling it, comprising Michael J. O'Brien, James B. O'Brien, Arthur Ferland, and others, to invalidate the location on the ground that it was obtained by fraud and misrepresentation. The case has been settled by consent, and the O'Brien syndicate granted a clear title upon their entering into an agreement to pay the Government a royalty of 25% on the value of the output at the mouth of the mine. This arrangement has naturally created great interest as forming a precedent for similar action in other cases of like character, and as showing the disposition of the Government to secure a larger share of the value of provincial mineral resources for the public. The action against the O'Briens, though in the name of the Government, was regarded as being in the interest of Messrs. Timmins, McMartin, and Dunlop, the big men of La Rose, who anticipated an opportunity to obtain the property, had the O'Briens been dispossessed. The course of the Government will arouse much criticism. It is regarded by other than the big mining interests as a timely concession to the growing feeling in favor of public ownership, the advocates of which have lately been active in urging the Government to secure more revenue from the mines. The O'Brien mine has undergone considerable development and before the proceedings were instituted shipped one carload of ore from which \$61,000 was realized.

At the Gilpin mine, Bucke township, a new calcite vein, carrying silver, has been found in shaft No. 2 at the depth of 13 ft. This makes the thirteenth vein struck on this property.—At the University mine there are 60 men at work. A compressor and electric-light plant are being installed, but the work proceeds slowly by reason of the scarcity of skilled labor.—S. D. Eplett, Fred Fisher, and James Kinier, leading Cobalt

prospectors known as the 'Big Three,' have sold their claim on Lot 1, Concession 4, Coleman township, to L. H. Timmins, N. A. Timmins, and David A. Dunlop, of La Rose, for \$100,000. It has 1,800 ft. of vein-matter uncovered, and shows cobalt bloom, intermixed with silver.—F. C. Loring, a well-known mining engineer, has been engaged as superintendent for the Tretheway Silver Cobalt Mines, Ltd.—B. B. Harlan has bought for \$250,000 a property known as J. B. No. 2, immediately adjoining the McKinley-Darragh-Savage and Silver Queen locations. It will be called the Little Nipissing and has been capitalized at \$650,000. A first-class equipment will be installed at once.—Steam machinery has been erected and is in operation in the Kinier shaft of

Map Showing Position of Cobalt and Lake Temiskaming.

the Temiskaming & Hudson Bay mine.—Dr. Robert Bell, formerly acting director of the Dominion Geological Survey, returned this week from his sixth visit to the Cobalt district, where he made a careful investigation.—At the Red Rock property a vein containing native silver, with high-grade ore and argentite, has been traced 200 ft. along the surface. A 40-ft. shaft is in operation and a carload of ore is ready for shipment. Capt. Joseph Harris is superintendent.

The continuance of open weather until late in the season has enabled the construction of the buildings of the Montreal Reduction & Smelting Co.'s works near North Bay to be completed. Sidings from the railway are being finished. It is hoped to have the plant at work early in January, but the company declines to make contracts as yet, since unforeseen delays may occur.—In blasting for foundations for a stamp-mill at the Grace gold mine in the Eagle Lake district, a new vein was discovered. The new mill, having a capacity of 50 tons per day, is supplied by the Allis-Chalmers-Bullock Co. Thirty-five men are at work under J. H. Caslor, the manager.—Anthony Blum, principal owner of the Laurentian gold

mine, Manitou Lake district, who has refused several very large offers to part with a controlling interest, will hand over the property to a company capitalized at \$5,000,000, of which stock he will hold the greater part. Prof. Hille recently visited the mine, and will make an exhaustive report to the Dominion Geological Survey. Development work is now being steadily pushed, the main effort being directed toward tracing the whole vein—the bottom of which has not been found. It is rich ore, known to be from 4 to 14 in. thick and 30 ft. long. The shaft is now down 280 ft., with no falling off in quality.

A great rush is reported to recently discovered placer gold diggings just east of Maidstone, in Saskatchewan. Gold has also been found at Birling in the same vicinity, which leads to the belief that the field may be an extensive one. A large number of claims have been staked and an influx of gold-seekers is settling on Maidstone, the nearest point that can be reached by rail. — Dr. J. S. Island, of Toronto, who has been experimenting on behalf of the Ontario Government to discover a process for the treatment of Cobalt ores, claims to have succeeded. He shows a specimen of the ore in matte form, 67% pure silver, and also the chemically pure silver withdrawn from it. He is certain that he has hit upon the formula employed in the New Jersey smelters, the secret of which has been jealously guarded.

London.

Tanganyika Concessions.—A Big Copper Region in Africa.—Financial Operations on a Large Scale.—Important Enterprise.—Old Botallack Mine to be Re-opened.—Activity in Cornwall.—Interesting Speech From Richard Pearce.—Dull Stock Market.

The long expected meeting of Tanganyika Concessions Ltd. has been held, and the event of the week is the issue of the £2,000,000 debenture prospectus. For some time previously many vain imaginings were indulged in by the market and the press as to the big financial scheme of which an inkling had been obtained. It was asserted with some show of reason that a South African house would be the sponsor for the new development. According to another account, an American group had come on the scene and would exercise a controlling influence on the future of the company. In this connection the Venture Corporation, as having its finger nowadays in many pies, was mentioned. Considering Belgian interests in the Congo Free State, it is a little remarkable that the financial co-operation from that quarter, which is now an accomplished fact, was not generally anticipated. It has taken effect in the registration of a mineral company under the law of the Congo State with its principal office at Brussels, under the name of Union Minière de Haut-Katanga, to acquire the whole interests in all the deposits already discovered in Katanga. The Mineral Company has £400,000 working capital, one-half of which is subscribed by the Société Générale de Belgique. A curious condition has been made that no shares of the Mineral Company can be dealt in for three years. The Tanganyika Company has created £2,000,000 5% debentures in bonds of £8 each, out of which its moiety of the Mineral Company's working capital will be provided, the remainder of the issue of debentures, over £1,500,000, being available for the Benguela railway through Portuguese West African territory to Katanga, just over the border of the Congo Free State. The debentures are convertible at any time at the option of the holders or up to December 31, 1911, into fully paid shares of the company at the rate of one fully paid share for every £8 of the nominal amount of the debentures. Any debentures issued for interest will carry similar conversion rights. The debentures

will be secured by a trust deed creating a specific first charge on 90% of the issued share capital of the Benguela Railway Company, and on the shares to be received in the Mineral Company about to be formed under the laws of the Congo State, less the shares reserved to commute prospectors' interests, and a first floating charge on all the other assets except the Rhodesian assets. It appears to be the intention to satisfy the interest accruing on any debentures up to December 31, 1911, by allotment of fully paid further debentures of the same series, but except for the purpose of paying the interest, no further debentures may be created to rank *pari passu* with or in priority to this issue. At the meeting, the managing director, Robert Williams, who together with his coadjutors George Grey, manager, and the engineers Farrell and Bayne, is likely to figure largely in the annals of North Western Rhodesia and the bordering region of the Congo Free State, gave a striking summary of the position of Tanganyika Concessions Ltd. in that belt of country now being reclaimed from desolation and savagery for commerce and civilization. He pointed out that with an issued capital of £525,000 they own 45% of the copper already proved to exist, amounting to 2,000,000 tons, which at only £50 per ton, represents £100,000,000 sterling. Taking half of this as profit, under economic working conditions there would be a profit of £50,000,000 of which the Tanganyika Company would be entitled to about £22,000,000; from values proved in only 10 of the 100 mines discovered. The Company also owned 65% of the Kansanshi mine, which has a proved value of about £500,000 in 20% ore, and which is within about a year of being connected by rail, besides 90% of the whole Benguela railway and mineral concession, with about £600,000 in a solid railway asset; and when the capital is issued up to the full £1,000,000, then the solid railway asset will amount to about £2,500,000. All this was apart from the tin, gold, and coal values. A few weeks ago a mile outcrop of coal was discovered which had given highly encouraging prospects. He believed the greatest copper industry in the world would be established and one of the greatest factors in carrying civilization into the very heart of Africa. Thus spoke Robert Williams, the pioneer, and in a great measure, the organizer of this vast undertaking, one of the most remarkable of modern times. The arduous nature of the work will be recognized from the fate which befell two of the gallant explorers, C. Cunningham, who was shot by a hostile band of natives in the Lunda district of Angola, and Mr. Bracken, who died of wounds resulting from being attacked by a wounded leopard in northern Rhodesia. The achievements of such men as these deserve something better than mere cavilling criticism. All the same it must be expected that the dry light of the market will seek to illumine the not always clear mind of the speculator who wants to know whether it is going "to pay." From this point of view a City editor appears to have arrived at an apt conclusion when he says: "The truth about the Tanganyika position seems to be that while the properties are of great potential value, much time is required for their development; and that because of the heavy speculation in the shares, these may suffer much before the properties become dividend-earning. The reports upon the properties are scarcely as explicit and as well-authenticated as they might be, but on the whole it seems safe to regard them as exceedingly rich. But the Benguela railway cannot well be completed for five years or so, and even the Rhodesia Railways extension—we understand the negotiations are almost completed—can scarcely reach the property for about a couple of years. Meantime the shares may be knocked about by the bulls and bears anyhow."

Changing the scene to Cornwall, we are brought face to face with conditions of an entirely different order. We seem to be bringing to light household gods from some long-forgotten room. Here is news that will awaken memories in the breasts of Cousin Jacks in many a rough and distant mining camp, and perhaps cause some of the white workers in South Africa to cast a wistful glance homeward where, if there is less money to be made, life may be less feverish and more complete. The Botallack Mines, Ltd., has been formed with a capital of £150,000 in £1 shares, and the Cornish Consolidated Tin Mines, Ltd., having acquired the properties, invite subscriptions for 100,000 shares at par, and Botallack will start with £60,000 in hand for working capital. The prospectus states that the company has been formed to acquire the Botallack and Buzza mines, situate in the parish of St. Just, seven miles west of Penzance, and, as at present constituted, comprising three setts, all adjoining, known as Botallack, about 200 acres; Carnyorth, about 150 acres; Buzza, or Truthwall, about 200 acres. The lodes on these properties have been profitably worked for tin and copper throughout a long period, although little is known of the results previous to 1802, while from that date to 1836 Botallack was worked only in a small way by five adventurers, who are stated to have divided £34,000 as profits. From 1836 the records of the first cost-book company show that the ores sold from Botallack from 1836 to 1895 were: Tin ores, value £829,664; copper ores, value £220,701; arsenical ores, value £6,481; total £1,056,846. The result of working Botallack mine for tin for the last five years immediately preceding suspension, namely, 1890-4 inclusive was: Black tin sold in the five years, 1,880 tons for £92,270. The average selling price of this black tin for that period was £49, while it is now about £120. Mr. William Thomas, who is to be the manager of Botallack, has been presented with a massive silver salver by the students of Camborne School of Mines on his retirement from the post of Mining Instructor at the School. It is reported that the Wheal Ellen group of copper and blende mines, adjoining the Tywarnhaile mines in the Porttowan district of St. Agnes, have been acquired by the influential Midland company, and they intend at once to develop the properties vigorously under Mr. Henry Gripe, of St. Agnes. In East Ellen nothing has been done below the deep adit (60 fathoms), although large and strong lodes are to be seen above this point. Already a shaft has been sunk to the deep adit, and skip and ladder-ways fixed. On the surface is an up-to-date head-gear with ore-bins. It is now proposed to sink this shaft to prove the lodes in depth, as well as to raise and dress the blende from the lodes now available for stoping. A neat and compact dressing plant has been installed, consisting of Cornish rolls, and several three-compartment jiggers and Green's patent vanning table and buddles. Turning to the old established mines, the accounts of Levant Mining Co. for the 16 weeks ending October 6, showed that upon an expenditure of £12,141 a profit of £7,168 had been made, as compared with an expenditure of £12,239 and a profit of £6,414 for the previous period. For the sale of tin £15,382 was realized, as compared with £14,425 for the other period, giving an average price per ton of £110. 8. 2 against £111. 12. 9. The copper sales brought in £3,112 as compared with £2,774. The balance in favor of the 'adventurers' amounted to £10,228. At the 'adventurers' meeting, the resolution was passed: "That after the next 16 weeks' working a sum equal to 10% of the dividend declared be divided amongst the staff, the tutwork men, and wages men, in proportion to the wages earned by them in that period." It is doubt-

ful if this policy will be generally approved in Cornwall. It seems open to the criticism that it may act unfairly in attracting the more skilled miners from the mines which want them most, that is to say, those undergoing development and exploration, but which cannot for some length of time reach the dividend-paying stage. The latest news from Grenville United mine is to the effect that the repairs to the 'bob' having been completed, pumping has re-commenced, and that a rich discovery of tin has been made (as predicted by the manager at the last meeting) in the 320-fathom level west of Fortescue's shaft. Samples assayed are said to have yielded 20% black tin to the ton of stuff. This discovery is a continuation of the great Flat Lode, the principal vein of the mine, and it will take some time to drive through it.

The annual meeting of the Royal Cornwall Geological Society was held at Penzance last week. According to a report in the *Cornish Post*, the president (Mr. Richard Pearce, of Denver,) in the course of his address referred, principally, to that branch of economic geology having a direct bearing on the mining industry of Cornwall. During the past year Cornish mining seemed to have taken a new lease of life, pessimistic despair had given place to the brightest expectations for the immediate future welfare of Cornish mining. Although that improvement was in a great measure due to the advance in the price of tin, another very important feature had been found to play a part in those improved conditions—the discovery that the tin lodes do not, in all cases, indicate barrenness as greater depth was reached. The recent developments at Doleath, at a depth of 3,000 ft., proved most conclusively that the old classic veins did not become exhausted at a paltry depth of 2,000 or 3,000 ft., and that lodes which had been found to be rich in tin at no very great depth from the surface, and had shown evidences of barrenness at deeper points, might still reward the pluck and enterprise of the miner, who had faith in deep mining, and the 'wherewithal' to prosecute his search. As tin appeared to be intimately associated with the older eruptive rocks, they were hardly warranted in thinking that tin veins became extinct, or had reached a point where they were no longer productive, at the very moderate depth yet reached by Cornish mines.

The nineteen days mining account just ended is said to be regarded as having been entirely undistinguished, except in the matter of dullness, without much prospect of better things in new time.

Some interesting details are published regarding the present position of gold and silver mining in Sumatra. The deposits on the island are now being worked by three undertakings, the Redjang Lebong, the Ketahoen, and the Lebong Simau. According to Mr. A. Yates, the assistant manager of the first-named company, these deposits have been worked from very early times, probably at about the same date as the Phœnicians were trading in Cornwall. The ancient workers evidently only scratched the surface, seeing that the longest galleries only extended to 150 ft. The lode is a quartz-breccia, and averages 15 metres thick; it assays over an ounce per ton, while the ratio of silver to gold is as 10 to 1. The present plant consists of 40 stamps, which it is proposed to increase to 70 stamps and six tube-mills in about five years' time. By means of an all-slime plant, which it is suggested should be provided, over 90% extraction will probably be obtained. The mill only gives about 3 dwt. gold, the sand-plant recovers about 80% of the sand-value, and the slime (filter-press) plant 94%. Working costs average about 35s. per ton, the high rate being due to transport difficulties, but these are expected to be reduced to 25s. per ton when work is undertaken on an enlarged scale.

Mining Summary.

ARIZONA.

COCHISE COUNTY.

The fourth furnace at the Calumet & Arizona smelter is now in blast. A fifth furnace, completed several months ago, is being held in reserve. At the mine, several improvements are under way, including a new machine-shop and a new blower. The old power-house is being torn down in order to make room for more furnaces. The management is evidently preparing for a bigger production.—Another smelter is to be built in the Globe district, according to H. H. Freeman, a mechanical engineer, representing the Mitchell Mining Co.; the site is to be on Pinal Creek, three miles from Globe. The capacity is to be 200 tons per day, and the ore is expected to come from the Five Points, Schulze, and Banker claims.—Good ore has been found in the Queen Mining Company's property at Superior. The old shaft of what was formerly a silver mine has been reopened to the 400-ft. level and good copper ore has been found both at that level and at the 300-ft. It is three or four feet wide and carries from 10 to 16% copper, together with some silver. J. W. Banhauer is superintendent. The ore will be shipped to the American Smelting Co. at Humboldt.—On Nov. 15 the workmen in the Warren mining district received an advance in wages at the rate of a uniform raise of 25c. per day. This applies to smelter employees also. At Globe a similar increase was given.—The new 10-drill compressor of the Globe Consolidated has been erected on the Gem claim and machine-drilling is now in progress. The shaft is being sunk rapidly under the direction of H. B. Hovland, the president of the company.—Charles S. Smith, the president of the Old Dominion Co., has gone to Globe to meet Mr. James Douglas and Mr. L. D. Ricketts in order to decide the question of building a railroad to bring the ores of the district east of Globe to the Old Dominion smelter; the acquisition of further mining territory is also to be discussed. It is possible that the smelter may be increased, as the old mine promises to maintain a large output.—A rich strike has been made in the Scanland mine, situated in the Paradise mining district. It is a large body of copper ore and it was found at 300 ft. deep. The ore is suitable for concentration.

The company known as the Arizona Mining & Development Co., in which C. G. Jones and others of Oklahoma City were interested, has been reorganized as a result of recent litigation, and is now operating the mines in the San Jose mountains, nine miles from Naco, under the name of the San Jose Gold Mining Co. The mill on the property has been operated at a profit of \$300 per day. The Shattuck-Arizona and the Denn-Arizona companies will erect a smelter to handle the output of their mines situated in the Warren district. The capacity will be equal to the output of the Shattuck mine, and plans will be made for the smelter's enlargement at such time as it may be necessary.

PINAL COUNTY.

(Special Correspondence).—The smelter for the Silver Bell mine at Kelvin is assured. A. G. Rockefeller, of Tombstone, has been on the ground to lay out the site. The plant will be situated eight miles south of Red Rock, on the hills that form the southern bank of the Santa Cruz river. All ore can be handled by gravity, and the smelter will be modern in every detail.—The re-timbering of the Wooley shaft of the Arizona-Pacific Co., under the management of S. C. Prunty, is proceeding rapidly.—R. G. Wilson has completed his second contract in the Copper Peak adit, which now has a length of 200 ft., all in copper-bearing breccia. It is probable that a diamond-drill will be employed to prospect the main vein, which lies against a typical trachyte uplift running parallel with the stratification of the copper-bearing breccia. The vein lies about 800 ft. north of the adit.—The Kelvin reduction plant is now running full time, having started leaching on Nov. 5 with J. M. Mead in charge.—The Zellenager new shaft, under the direction of J. L. Powell, is progressing rapidly and is down 70 ft. They expect to connect with the vein in the

old workings in two weeks.—James Elder, who has a lease on the old Ray dump at Kelvin, has three carloads of high-grade ore ready for shipment to the smelter at Humboldt.—The Big Lead Co. at Kelvin is completing its 10-stamp mill, which will be so constructed that after leaving the crusher the ore will pass through the plant by gravity.—The Buckeye-Calumet-Arizona Mining Co. is to begin making regular shipments of ore next week.

Phoenix, Nov. 19.

YUMA COUNTY.

The Reliable group of claims situated near Quartzsite has been sold to the Ventura Mining Co. organized by New York capitalists. Negotiations were closed in New York by Hugh Creighton, brother of H. S. Creighton, the owner of the mine. The Reliable group was purchased two years ago by Creighton from Mercedes Downey of Yuma, and consists of seven claims, situated four miles north of Quartzsite, in the Plomosa district. Five hundred feet of development has been done, on a lode nine feet wide, a mill-test of 100 tons of ore yielding \$12.80 per ton.

CALIFORNIA.

INYO COUNTY.

A shaft sunk on the Furnace Creek Copper Co.'s property has reached a depth of 275 ft. with a cross-cut at

250 ft., which has uncovered an orebody 300 ft. wide. This mine, being the most developed among Greenwater claims, ranks first in value, with the Schwab property a close second and the Copper Shoes of the Furnace Creek South Extension Co., third.

LOS ANGELES COUNTY.

E. A. Gray and associates are working the river bottom in the San Gabriel cañon with some success, and have taken out a number of nuggets from the gravel at the Horse Shoe placer. The placer is situated 30 miles from Azusa, just below the narrows. The San Gabriel yielded \$14,000,000 worth of gold in the days before hydraulic mining was stopped.

NEVADA COUNTY.

Work is to commence shortly on the long adit of the Bear River Con. Co.—A new tunnel has been commenced at the Jenny Lind gravel mine to strike the ancient river bed. It has been decided to extend an old tunnel, some distance above the one through which operations are now carried on, and thus secure direct communication with the gravel bed. On the completion of the new tunnel, the old system of

working will be discarded. The mill is kept running on gravel of fair value.

SAN BERNARDINO COUNTY.

A new mining region is being opened up in the Avawatz Mtn., adjoining the westerly edge of Death Valley. Widely scattered arastras, however, show that Spanish miners worked the surface nearly a century ago. The camp has been organized into the Crackerjack district, and is about 36 miles square, 60 miles northwest of Daggett, the nearest railroad point being Silver Lake station, 23 miles distant, to which the Tonopah-Tidewater R. R. has lately been completed. Gold, copper, silver, and lead are found, and the district is generally considered to be a continuation of the Tonopah, Goldfield, Bullfrog, and Greenwater mineral belt. The Crackerjack Co. has four claims, on which a shaft is being sunk all in ore. A three-foot vein assaying \$114 and a two-foot vein running \$128 per ton have been opened up. Adjoining the Crackerjack on the southeast is the Tomboy, a group of claims owned by Los Angeles people. Although but little work has been done on this property, assays are said to run high and the continuity of the orebody is shown by a cañon outcrop 200 ft. deep. The Beck & Wilson group has an outcrop of ore from 6 to 12 ft. wide. The workings yield ore from \$11.55 to \$75 per ton. The district has already had its first milling, the result being a gold brick worth \$1,200, from the Rose & Palmer claims. A townsite will be laid out at once adjacent to the Crackerjack claims, and a stage line is soon to be operated from Silver Lake station.

SHASTA COUNTY.

The Mammoth Co. has installed two additional blast-furnaces at their Kennett plant. Two large converters are also to be added, in order to supplant the present practice of shipping matte to Utah. A big machine-shop is to be built commensurate with the improvements to the plant. Twice the present number of men will be required, and the future smelter as planned will be the most complete plant yet built in California. At the Mammoth mine a compressor, four times the size of the one now in use, is to be installed, capable of operating 35 to 40 drills. This company is also setting up a five-drill compressor at the Quartz Hill mine.

SISKIYOU COUNTY.

The St. Louis Co., which recently purchased 100 acres along the Klamath river in the Riverside district, is about to start vigorous mine-development.

TRINITY COUNTY.

The Trinity gold placer, on Coffee creek, cleaned up for the season on Nov. 10. M. P. Rose is running a tunnel on his property, near the Nash mine, and has found some good-looking ore. Tom Keating has commenced to build another arastra 100 ft. below the site of his old machine. The greatest activity in this district is around the Bonanza King mine, of which Joseph Porter is manager. The Jubilee mine is employing 20 men and it is expected to run throughout the winter.

TUOLUMNE COUNTY.

(Special Correspondence).—W. A. Nevills will soon become the sole manager of the Rawhide and App mines again, according to reports. He has borrowed \$100,000 from the Central Loan & Trust Co., of Fresno, to liquidate the indebtedness on these properties, giving a deed of trust as security for the loan. Many look forward to much greater activity at Mr. Nevills' mines in the near future.—The Yankee Hill Co. filed articles of incorporation in this county last week. The capital stock is \$30,000, with shares at \$50 each. The amount subscribed is \$25,000, and the principal place of business is Columbia, Cal. The directors are J. Tom Williams of San Antonio, Tex., Will L. Vining of Austin, Tex., and S. H. Robinson, Irvin Lewis, and L. Kress of Columbia, Cal.—It is reported that a wealthy company will soon begin operations at the Mountain Bell and Parallel mines, situated near Soulsbyville. Considerable development work has been done on the former and rich ore taken out, some of which yielded \$70 in free gold per ton. Work was discontinued, however, by the owners owing to lack of machinery. The Mountain Bell vein is supposed to be the same as the Soulsby, the Mountain Bell being a short distance north.—Development work is being pushed at the

Oak Hill mine, in the western part of this county. The crew employed was augmented this week. The outlook for this property is decidedly good.—San Jose people have bonded the Mt. Hood, situated near the Rawhide, and are having the mine unwatered.

Tuolumne, Nov. 19.

The Wheal Rough mine, idle for many years, is to be reopened. The property is situated in the Soulsbyville district, and on the same vein as the Black Oak. The last work done on the Wheal Rough was in 1868, when it was closed down by its owner, the late E. Richards, a merchant of Sonora. The shaft is 108 ft. deep, with two 60-ft. drifts from the bottom, and the quartz is stoped out to within 40 ft. from the surface. The vein is said to be from one to two feet wide and yielded from \$30 up to as high as \$112 per ton in free gold, no concentrates being saved in those days. The mine has been purchased by a company from Mrs. E. C. Wetmore and C. M. Richards, and a force of men will at once be put to work to clean out the shaft.—Rich ore has been struck at the Yorktown mine on the Ida Klein ranch, near Stent. The property is being developed by Messrs. Lyon, Baum, & McFarland, who have an efficient hoisting and pumping plant in operation. The shaft is down 60 ft. with a cross-cut that has cut the vein.

COLORADO.

BOULDER COUNTY.

The Eastern purchasers of the Copper King group on Boulder Mtn. have given instructions to proceed with development, and to secure U. S. patent to all of their unpatented claims. The main adit to cut the Copper King vein will be started on the west end of Boulder Mtn., and will strike the vein 1,000 ft. from its portal, at a vertical depth of nearly 1,000 ft. The ore is a lead sulphide, carrying silver and some gold. The vein is over 100 ft. between walls, a large proportion being rich enough to justify shipment in the crude. The new company proposes to erect a large mill at the bottom of Hancock gulch next summer, which will be connected with the mine by means of the improved Bleichert tramway from the mouth of the adit. An air-compressor will be installed, and work will be pushed until the vein is intersected. In the meantime the upper workings will be developed.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Chamberlain sampling works report an increase in ore shipments of 50%. The Ramsdale Co., recently incorporated, has now completed its boarding-house, ore-house, and blacksmith shop at the mine on Lincoln Mtn. The lode for a width of three feet assays from 0.5 to 2 oz. gold, 30 to 80 oz. silver, 34 to 40% lead. The company is planning to build a concentrating and cyanide plant, for which bids will be called immediately.—The Stella Mining Co. has taken hold of the Antelope mine on Republican Mtn., and is now driving the main adit.—The Georgetown Leasing Co. is making good progress on the Lone Tree and Brannigan lodes on Leavenworth Mtn., and expect to be shipping pay-ore shortly.—The Main Gulch Mining Co., operating the Smuggler mine above Silver Plume, made a 100-ton shipment of lead-zinc ore of the usual grade this week. The shaft is now down 260 ft. and will be sunk 150 ft. more. On the 176-ft. level, 70 ft. east of the shaft, there is two feet of silver-lead ore; west from the shaft there is also a fine orebody.—John Reily and Joe Roehel, who have a lease on the Sceptre lode on the Red Oak property, Democrat Mtn., have just opened up two feet of ore that assays 124 oz. silver per ton, 15% zinc, and 20% lead.—Dave Crandell, while doing the assessment work on the McKinley lode, adjoining the Ramsdale property, opened up a foot of ore that assays as high as 10 oz. gold per ton.—The Southern Co., working the Poor Man's Relief and other lodes, has let another contract to drive the adit 100 ft., to the junction with the R. E. Lee lode.—The old Peruvian mine, in the horseshoe over Argentine pass, is now being put in shape for extensive development work by a group of Idaho Springs mining men. This property has a good record.—The Key West Co. is driving the McKinney adit, and in the raise at 350 ft. from the entrance there is a

fine body of concentrating ore, averaging \$10 per ton.—At 100 ft. from the portal of the Plebian adit on Columbia Mtn., a 12-in. vein, assaying from 100 to 350 oz. silver, has just been encountered.—The Charter-Raton Co. has now completed the erection of its 80-h.p. air-compressor plant. The machine-drills are at work driving La Moe adit ahead. Charles Morris is superintendent.—The Capitol Mining & Tunnel Co., of which William Cooper is superintendent, is still driving the main adit, although the ore recently encountered, while passing through the Ætna lode, is three feet wide and worth \$30 per ton. Before working this orebody it is the intention of the management to have everything in readiness so that continuous shipments can be made. Large ore-bins are being built, and after proper tests have been made to ascertain the best method of concentration, the company will erect a plant of its own, having purchased several town-lots this week as a millsite.

Georgetown, Nov. 16.

(Special Correspondence).—The Dives-Pelican mill is being remodeled so as to increase its capacity. An aerial tramway, in addition to the one already installed, is being added to the plant and will transport ore from some of the old dumps to the mill. The tramway when completed will be about half a mile long. A 1,000-ton storage-bin is being erected at the top of the mill and the crushing department will be adjacent to this bin instead of at the bottom of the mill as at present. The ore will be drawn from the bin to the crusher and from there through a Crane washer, over a sorting device, through the jigs, to the concentrating tables. It will require about two months to complete the equipment.—It is understood that McGrath & Stevens cleaned up during the past year about \$24,000 from their lease on the Mendota mine and dump. During the summer months they operate on the dump and block out ore in the mine. In the winter the ore is brought from their lease in the mine and put through the mill, which has a daily capacity of 50 tons.—The Scotia Mines Co. (J. H. Crawford, general manager) is operating its mill on ore from its own mine. This mine was operated up to the time of the panic of 1893, but since that time little work has been done until the present company assumed control. The mill is capable of handling 50 tons per day.—Joe. B. Warner, for many years manager of the Ledge mine near Silverton, and now representative of the Nashotah Mines Co., is constructing a mill with a daily capacity of 250 tons to handle the ore from the old Cory mine. It is estimated that the dump contains 500,000 tons and that there is about the same amount in the stopes; all of this stuff will be put through the mill. This mine was operated more than thirty years ago when nothing but high-grade material could be exploited on account of the difficulty of transportation at that time.

One of the big enterprises of upper Clear Creek county is the Vidler tunnel, which is being driven under Argentine pass by Rees C. Vidler and associates. He is operating at present from both sides of the mountain and recently opened up an orebody about 10 ft. wide, which is being explored vigorously. It is estimated that there is enough ore in sight to keep the 100-ton mill supplied for a number of years. This mill, which was furnished by McFarlane & Co., of Denver, will be running within thirty days. During the past summer Mr. Vidler has installed a large steam plant consisting of two 80-h.p. boilers, making a total of three boilers; one double cylinder Rand compressor, 1,500 cu. ft. per minute, furnished by Cary & Fielding, of Denver. A large Connersville blower has been installed, which it is estimated will clear the atmosphere at the breast of the tunnel in about 15 minutes. A few days ago the first vein of the Colorado Central system was encountered and shows three feet of pyrite.—The Denver & Transcontinental Ry. was recently incorporated by Charles Baldwin, of Colorado Springs, and Rees C. Vidler, of this place. The object is to construct a standard gauge track from Denver up Clear Creek, through the Vidler tunnel to Argentine and to Leadville, from there to Salt Lake City and San Diego, California. A large corps of surveyors is now in the field selecting the best route for the road. Should this road be

built, it will open up a large territory as yet undeveloped on account of the lack of transportation facilities. As a scenic road it will be a success, for it goes through some of the most picturesque mountains in Colorado.—The old Doric property is being operated under lease by the X-Ray Gold Mining Co., of which James Cousins is superintendent. They have recently made a shipment of ore which averaged 15% copper, 3 oz. gold and 40 oz. silver per ton. This company is making a raise to connect with the Grif-fith, which will give both properties good air when the connection is made.

Georgetown, Nov. 17.

SAN JUAN COUNTY.

The Joe and John mines in Prospect Basin have been sold by Mrs. Katherine Luttrell to a Boston syndicate. The purchase price is stated to be over \$100,000; the first payment has been made and the new company is now in possession, R. W. Hollis having been appointed manager. New ore-bins, blacksmith and carpenter-shops are being built so that work can continue uninterruptedly through the winter. In the spring a complete plant will be installed.

NEVADA.

ESMERALDA COUNTY.

The speculation in stocks makes Goldfield extremely lively. Visitors are coming to the camp from everywhere and the stories of new consolidations arouse great interest. It is known that the Combination is bonded to Nixon and Wingfield in behalf of the Goldfield Consolidated and that a deposit has been made in San Francisco. There is a good deal of talk about a million-dollar shipment of ore from the Mohawk, it being a fact that those in control of two leases, namely, the Hayes-Monette and the Frances-Mohawk, are accumulating sacks of high-grade ore for a big shipment. From the Frances-Mohawk lease the output is being crowded; it is at the rate of 350 tons weekly of stuff that averages \$250 per ton. The ore is from 8 to 10 ft. wide and contains much free gold. The shaft is 85 to 100 ft. long. It has been stoped at a depth of 300 ft. and to within 100 ft. of the surface.

LINCOLN COUNTY.

(Special Correspondence).—The Searchlight district is now the scene of marked activity, as is evidenced by the sales and transfers of different properties in the camp. A new townsite is being platted at the terminus of the Barnwell & Searchlight R. R. on the flat west of the original townsite.—A sensational copper strike was made recently, 13 miles east of Searchlight, by Thomas Turpin and D. S. Macrea, in the vicinity of Camp Thurman. The vein is 64 ft. wide, and is plainly traceable for a distance of 1,200 ft. Five assays average 6% copper, with some gold. Twenty-six claims have been staked out in the new district. The management of the Searchlight Parallel is sinking an incline 600 ft. west of the present shaft. Owing to the dip of the lode it is estimated that with the new shaft the ore can be extracted at a great saving. On the 500-ft. level 20 ft. of ore has been encountered in a cross-cut; it will average \$16 in gold. Water has been developed in sufficient quantities to run 100 stamps, if necessary:—A contract has been let by the management of the Goldyke Co. to sink the present shaft to water-level, and also to retimber the old workings. The assays obtained during the development work have been very gratifying and work will be prosecuted with vigor.—At a depth of 240 ft. the Wyoming-Searchlight has encountered water and sinking has been suspended pending the arrival of pumps. Drifts are being run at the 100 and 200-ft. levels to the west.—A big vein has been opened up on the King Solomon claim of the Superior Nevada. Five feet of ore assays 7% in copper and two ounces in gold. A tunnel is being run into the side of the mountain to cut the lode; it is estimated that 240 ft. of work is required.—The vein traversing the entire length of the Euchre claim of the Duplex Extension property has been sampled; the assays were satisfactory.—Recent explorations on the lower levels of the Cyrus Noble mine have shown that the casing of the vein carries gold and silver. What was hitherto considered barren waste below 200 ft. is now being thoroughly sampled. H. E. McCrea, super-

intendent of the Mondamin, is making a survey of that property. The present shaft is down 145 ft. in five feet of ore that will average \$18 per ton. A 15-h.p. Fairbanks-Morse gasoline hoist is to be installed. — Sinking is still proceeding at the Channel City group, four miles west of the Quartette mine. The shaft has reached a depth of 110 ft., and the vein-matter is becoming better defined. Samples from the bottom of the shaft ran from \$14.20 to \$35.40 in gold, with a trace of silver.

Searchlight, Nov. 12.

NYE COUNTY.

(Special Correspondence).—Rumor has it that the Nevada Southern railway has changed hands and that the new owners will extend the line to tap the northern portion of Nye county. The new camps tributary to Manhattan would profit by such a road and local interest is much attracted by the talk. Among those said to be prominently connected with the scheme are C. S. Lemon and Harry Overman.

A number of Manhattan operators have returned from the vicinity of Dutchman Creek and neighboring camps started by the opening of the Walker Indian reservation. Some fine specimens of gold, copper, and lead ore are exhibited by those who attended the rush and valuable mines are expected in the new territory. However, local people are generally returning well satisfied with prospects nearer home.

A large mill seems to be assured within the near future, as several groups of investors have been investigating the possibilities of custom milling. The Tonopah Exploration Co. has shown more activity than others; these people have surveyed for a pipe-line from their water source, some ten miles distant, in Jett cañon, and they have commenced excavating for the line. The company's holdings include the Little Grey property where there is a large body of ore of milling grade. John Robertson is in charge of the work on the ground. A three-stamp mill has been crushing for several months.

A recent find of copper ore between Cloverdale and San Antonio has been the recent centre of attraction. A town-site is being laid out, bearing the name of Copper City, and the Superior mining district has been organized with Morris Fenbach as recorder. The water supply is at Bank spring on the Pearing road and is only two or three miles from the strike. Average surface samples are said to give returns of 7 or 8% copper, 4 to 5 oz. silver, and about \$1 in gold. J. B. Giffen, of the Giffen Mercantile Co., is one of the principal owners.

The properties to the west of the town are showing considerable activity. Among those that reported good finds recently are the Original, Giant, and Hooligan. A large proportion of the miners employed in the district are in this neighborhood, that is, around Central City.

The Seyler-Humphrey, Consolidated, and Pine Nut mines are active in development. The first is operating with a gasoline engine and the other two are hoisting with steam-power. All have reached water-level, which varies between 100 and 200 ft. below the surface.—Over the summit, toward East Manhattan, copper croppings are being opened up at several places. The chief operator is the Toquimo Copper Company.

Local stocks show a slight upward tendency owing to encouraging reports from the properties and the general effect of the rise in Goldfield shares. A generally optimistic tone is prevalent and the effect of the slump due to the San Francisco disaster appears to be past. About 150 miners are employed near town.

Manhattan, Nov. 18.

Charles J. Kanrohat, owner of the Sierra Nevada mine at Jefferson cañon, is arranging the sale of that property to an Eastern firm for \$175,000. There are 16 claims in the group. —The vein on the Nevada Wonder group at Wonder is said to be proved to a depth of 110 ft., showing an average width of 13 ft. and value of \$100 per ton.—A group comprising four claims adjoining the Stray Horse and Castle Rock has been purchased by Patrick, Elliott & Camp of Goldfield. The original locators had succeeded in open-

ing up shipping ore at three different points on a vein which runs directly through the property, and bisects the entire northern portion of the camp.—The strike of a rich stringer is reported at the Fairview-Round Mountain mines in the bottom of No. 3 shaft. The stringer is 3 in. wide and rich in free gold.—The old Charles mine in Jefferson cañon has been sold to C. O. Olive, Nelson Rounsvell, Fred Tarbell, and associates. The property has been worked by Charles Harrison for 35 years, and there are over 3,000 ft. of workings. In the '70s several sensational runs were made through the old mill in Jefferson cañon, the output in the year previous to the demonetization of silver being \$160,000. Harrison was one of the few who did not abandon his silver properties, and from time to time with a crude home-made arrastra he treated small lots of high-grade ore taken out in the course of prospecting. The group has a total of 18 claims and has been incorporated as the Round Mountain Allegany. The Charles mine takes in the principal claim of the group, and will be cleaned out at once, then sampled, and a test run made to determine the character of mill required. A water right goes with the deal that is reputed one of the best in this part of the State.—The first mint returns from Round Mountain ores have been received from several runs made through the Moore & Chapman mill two weeks ago. W. Munholland, owner of the lease on the Daisy fraction, heads the list with a check for \$2,981 from the San Francisco mint. This was for a net weight of 209.94 oz., or nearly 18 lb. bullion. The gold was of a fineness of \$14.39 per oz.—The Round Mountain Imperial Co. is developing the Mary McLane fraction. At a depth of 71 ft. a drift was started which is now 45 ft. long in gold. This company also owns the Annie Rooney fraction and four claims about 3,000 ft. south of the Cahill. These show strong outcrops. Little work has been done on these veins, but surface assays gave an average of \$18.82.—Three machines are being run at the placer diggings on the Sunnyside claim of the Round Mountain Co., and the Blue Jay claim of the Combination Mining Co. From the latter a clean-up was taken last week amounting to 211 oz. The gold will run about \$14 per ounce.

CANADA.

BRITISH COLUMBIA.

While the coal miners' strike has cut down the output of ore from the Rossland mines, it has made little difference in the number of men employed. At Le Roi, for example, the number of men has been increased with the development work in progress. The Centre Star, White Bear, and Mabel have about the same forces as usual.—The widening of the lode in the Mabel to four feet of shipping ore, reveals that there is some good ground in that vicinity. The shaft of the Centre Star has reached the thirteenth level, which is 1,800 ft. from the collar, making it the deepest shaft in the province.

The report for the six months ending June 30, 1906, submitted recently by W. H. Aldridge, managing director of the Consolidated Mining & Smelting Co., Ltd., of Canada, shows that, after writing off expense of incorporation and \$45,905 as depreciation upon plant and equipment, the operating profit is \$325,854. The gross value of metals produced by the smelting works has been over \$22,000,000, and during the six months the gross value was about \$3,000,000, of which \$1,622,450 came from the company's own properties. Referring to the development work upon the group of claims controlled or operated by the company, Mr. Aldridge states that 14 miles of underground work has been done in the Centre Star and War Eagle, and nearly eight miles in the St. Eugene. In order to secure a regular supply of smelting ore, the Consolidated Co. has entered into an arrangement by which it will operate the Snowshoe gold and copper mines under lease. Since the close of the fiscal year, negotiations for the purchase of the Iron Mask mine have been concluded. This property adjoins the War Eagle on the east, and the Centre Star on the north. In the past there has been litigation between the Centre Star and Iron Mask which this purchase will render impossible in future. Owing to personal reasons, James Cronin has resigned active management of the mines, and has been replaced by R. H. Stewart.

Personal.

J. H. CURLE is in the Tyrol.
OLIVER WETHERED is at New York.
ARTHUR WINSLOW is in San Francisco.
CHARLES BUTTERS is on his way to Salvador.
R. GILMAN BROWN is on his way to New York.
W. R. VAN LIEW is at Bloomfield, N. J., on a visit from Russia.
W. E. RENSHAW, of Idaho Springs, Colo., is in New York.
H. W. TURNER is examining mines in Sierra county, California.
GEORGE H. EVANS is examining mines in Kern county, California.
FRED JONES has recently returned from Goldfield, Nev., to Denver.
EDWARD SKEWES has left Texada Island, B. C., on his return to London.
ALTON L. DICKERMAN has returned to Colorado Springs after a long absence.
DAVID MCCLURE, manager of the Gwin mine, is on a visit to San Francisco.
R. W. HOLLIS is manager for the Joe and John mines near Silverton, Colorado.
JOHN T. KEEGAN is operating the May-Flower mine at Idaho Springs, Colorado.
JOHN A. MCLEAN is now manager of the Mayflower mine, at Howard, Oregon.
C. F. BORELL is superintendent of the Dives-Pelican mill at Silver Plume, Colorado.
D. J. PULLINGER, of London, is expected in San Francisco from Mazatlan, Mexico.
THOMAS HOATSON and JOHN HOATSON, of Calumet, Mich., are at Bisbee, Arizona.
JEROME SMITH is manager for the Democrat Mtn. M. & M. Co. at Georgetown, Colorado.
JESSE J. MACDONALD is now at 301 Livingston Hall, Columbia University, New York.
FRED. G. FARISH has returned from Helena, Mont., and is now on his way to Mexico City.
E. A. WEINBERG is acting as advisory engineer to the Mt. Elliott Co., at Cloncurry, Queensland.
D'ARCY WEATHERBE has accepted the management of a copper mine in the Argentine Republic.
LEO VON ROSENBERG passed through San Francisco on his way from Idaho to Prescott, Arizona.
CHARLES F. SHELBY has left Globe, Arizona, and is now with the Greene Con. Copper Co., at Cananea.
S. H. WORRELL is manager of the Rey Solomon mine, in the Santa Eulalia district, Chihuahua, Mexico.
C. W. MERRILL, metallurgist to the Homestake Gold Mining Co., is visiting his home at Alameda.
F. C. ROBERTS has come from Ventanas, in Durango, Mex., to order machinery from San Francisco.
JOSEPH C. ERMAN is now general manager for the Troy-Manhattan Development Co., at Troy, Arizona.
J. A. STEWART, of Houghton, Mich., is now at De Lamar, Idaho, with the De Lamar Mining Co., Limited.
DEANE P. MITCHELL is now manager of the Oroya-Brownhill mine at Kalgoorlie, Western Australia.
J. B. WARNER is manager for the Nashotah Mines Co. at Silver Plume, Colorado, with headquarters at Denver.
E. C. ENGELHARDT has been appointed manager for the Hercules Gold Mining Co., at Deadwood, South Dakota.
WALTER P. JENNEY, who is now at Tonopah, has been examining mines in the Uba Hebe range, in southwestern Nevada.
W. W. BRADLEY has resigned as mill foreman for the Standard Con. Mining Co. at Bodie, Cal., and he is now at Berkeley.
KEIJIRO NAKAMURA, chief metallurgist at the Besshi

copper mine in Japan, is visiting the copper mining regions of America.
DONALD CLARK has been appointed director of the Bendigo School of Mines, resigning a similar position at Bairnsdale, Victoria.
REES C. VIDLER, of Georgetown, Colo., sails on December 8 on the *Campania* for London, where he will be for some time at 53 New Broad St.
N. C. GROCH, of Deadwood, S. D., and FRANK HALL, of Telluride, Colo., are now with the New York & Honduras Rosario Mining Co. in Honduras.
T. E. SCHWARZ, consulting engineer for the Iron Silver mine at Leadville, and the London mine at Alma, has returned to Denver from an inspection of these properties.

Obituary.

MARCUS MAACK, late manager of the Blue Ravine mine, in Sacramento county, died at Oroville, in Butte county, California, on November 7. His fatal illness was typhoid pneumonia. He was one of the best miners in the State and was highly respected for his uprightness of character and kindness of heart. Cut down in the prime of manhood—for he died when only 36 years old—he will be mourned by many friends.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

INFLAMMABLE GASES are found even in metalliferous mines, usually in old workings where the carbureted hydrogen has been generated from rotting timber in water.

CHEMICAL INVESTIGATION of many eruptive rocks has detected the presence of gold and silver under such conditions as to leave little doubt that they were original constituents of these rocks.

THE discoveries connected with radio-activity have enormously increased the estimated stores of energy surrounding us, but these stores have not yet yielded up mechanical effect for the use of man, if we except the radium clock.

METALLIC GOLD occurring in pyrite is sometimes coated with a film of sulphide of iron or other base metal so thin as to be unnoticed, the color and lustre of the gold being maintained. This, however, is often sufficient to prevent amalgamation.

THE complete cost of a one-story iron building, such as would be suitable for a furnace shed, storage house, etc., is 40 to 60 cents per square foot of ground covered. A building 309 by 42 ft., weighing 10.5 lb. per sq. ft. cost 44.65c. per square foot.

IN 1877 telluride ores were discovered in Boulder county, Colorado. Two years later these ores were found in La Plata county, and in 1891 the most notable and productive deposits of the world were discovered at Cripple Creek, in the same State.

WHEN a corrugated iron roof is to be laid on boards nailed to the rafters, it is advisable to lay waterproof paper between the iron and the boards, especially in buildings where steam comes in contact with the roof. The paper makes the building warmer and prevents dripping.

PLAIN GLASS, wire-glass and ribbed glass are all used for glazing the windows and skylights of factory buildings. Ribbed glass should be placed with the ribs vertical, otherwise the glare is apt to be trying. Wire netting should always be stretched under skylights of ordinary glass, to prevent accidents in case of breakage.

GALVANIZED IRON is unsuitable for buildings intended to contain furnaces that will develop sulphurous fumes, since these will corrode the zinc with which the iron is coated, and the galvanic action set up between the remaining zinc and the uncoated iron hastens the destruction of the latter. Painted corrugated sheet iron becomes preferable.

ASBESTOS is a general name given to the fibrous varieties of two distinct minerals—serpentine and hornblende. Chrysotile, the porous variety of serpentine, is exclusively mined in Canada. Associated with serpentine, the asbestos occurs in numerous veinlets, seldom more than 3 in. thick, which traverse the rock in all directions.

ORDINARY corrugated iron receives one coat of paint at the rolling-mill, the paint usually employed being red oxide of iron thoroughly ground in pure linseed oil, with enough drier mixed in to give it proper drying quality. The first coat of paint is applied by machine, and likely to be imperfect, wherefore the sheets should be painted again after putting them on the building.

TWENTY-FIVE years ago Lord Kelvin summarized the stores of energy from which mechanical effects can be drawn by man as follows:

1. The food of animals.
2. Natural heat.
3. Solid matter found in elevated positions.
4. The natural motions of air and water.
5. Natural combustibles.
6. Artificial combustibles.

The quarter century which has elapsed since the foregoing summary was announced has not made it possible to extend this list.

A OWNS a mining claim of which B is in possession under an option to purchase, such option being silent as to assessment work. B, while in possession under the bond or option, performs work on the claim to the value of \$700. Will such work enure to the benefit of the owner and be counted as assessment work?

Yes. B has the equitable title to the ground, and anything he does toward its development or protection would enure to the benefit of A if B failed to complete purchase.

A OWNS a mining claim. B, a creditor, obtained a judgment against him, levied upon the property, and it has been sold at sheriff's sale. During the redemption period may B perform the assessment work, so as to prevent the re-location of the claim?

Yes. Assessment work may be done by either A or B; and it will enure to the benefit of A, if he redeems, and of B, if there is no redemption. During the period of redemption B holds the equitable title, and may take all steps necessary to protect the property. As to whether in the event B does the work and A subsequently redeems, B could compel A to re-imburse him for the work done, is another and doubtful question.

A LOCATES a quartz mining claim across patented placer ground. He makes a discovery outside the placer boundaries. The vein on its course enters the placer claim. It is asked if he may follow the vein on its course underneath the placer surface from his workings outside.

If the lode was known to exist within the placer boundaries prior to the application for placer patent, he may so follow it. If its existence became known subsequent to the patent application, he cannot follow it, as so much of such vein as is within the placer boundaries belongs to the placer patentee. As to whether A might follow the vein on its downward course, underneath the placer, is a distinct question—not asked—and which cannot be answered without further information as to precise position of the apex of the vein within the lode location-boundaries.

WHILE the laws governing the occurrence of ground water in unconsolidated materials and in porous sedimentary formations are now generally understood, little has been written concerning the sources of supply for wells in the so-called crystalline rocks. The most favorable points for water are at the intersection of two or more of the joint systems, the circulation being often concentrated at these points. It is impossible to foretell the success or yield of a well in crystalline rocks, but the chances of a moderate supply are at least as good as 9 in 10. The character of the water obtained is in general excellent, both for domestic and manufacturing purposes, and is usually soft. Hills and places where the soil is thick are the most desirable locations for drilled wells. In general it is better to abandon a well and seek a new location if not successful when a depth of 250 ft. has been reached, as the possibilities of a supply below this depth are much less than at shallower depths. The average cost of 123 wells, averaging 108 ft. in depth and yielding a mean of 12.7 gal. per min., is \$4.25 per foot.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Comparative Tests Between Coke and Crude Oil for Melting Precipitate.

The Editor:

Sir—It may interest your readers to know that two experiments were made at the Butters Salvador mines, in Salvador, to determine the relative efficiency of coke and crude oil in melting precipitate from the cyanide plant; the first was on the ordinary San Sebastian clean-up from the acid refining box, and the other was on silver precipitate from Divisadero. The costs are calculated on a basis of coke at \$0.0208 (gold) per lb., and oil at \$0.252 (gold) per gal. laid down at San Sebastian; white labor at \$3 per shift of 10 hours; and compressed air at 1c. per hour.

FIRST TEST.			
OIL.	Sept. 11, 1906.	COKE.	Sept. 13, 1906.
Precipitate.....	2,448 oz. Troy	Precipitate.....	1,991 oz. Troy
Oil.....	15.2 gal.	Coke.....	221 lb.

Cost of fuel per 1,000 oz. of		Cost of fuel per 1,000 oz. of	
precipitate.....	1.56	precipitate.....	2.31
Cost of white labor per 1,000		Cost of white labor per 1,000	
oz. of precipitate.....	0.91	oz. of precipitate.....	1.25
Cost of air per 1,000 oz. of			
precipitate.....	0.03	Total.....	\$3.56
Total.....	\$2.50		
Balance in favor of oil per			
1,000 oz. of precipitate.....	1.06		
Total.....	\$3.56		
SECOND TEST.			
OIL.	Sept. 20, 1906.	COKE.	Sept. 21, 1906.
Precipitate.....	5,864 oz. Troy	Precipitate.....	3,524 oz. Troy
Oil.....	21 gal.	Coke.....	283 lb.
Time.....	10½ hr.	Time.....	10½ hr.
Cost of fuel per oz. of pre-		Cost of fuel per oz. of pre-	
cipitate.....	\$0.00093	cipitate.....	\$0.00167
Cost of fuel per 1,000 oz. of		Cost of fuel per 1,000 oz. of	
precipitate.....	0.93	precipitate.....	1.67
Cost of white labor per 1,000		Cost of white labor per 1,000	
oz. of precipitate.....	0.55	oz. of precipitate.....	0.86
Cost of air per 1,000 oz. of			
precipitate.....	0.02	Total.....	\$2.53
Total.....	\$1.50		
Balance in favor of oil per			
1,000 oz. of precipitate.....	1.03		
Total.....	\$2.53		

Thus, in both these tests, on entirely different classes of material, we get a uniform result, which shows strongly in favor of the crude-oil method of melting, at least as far as the Republic of Salvador is concerned. There are other advantages connected with the use of oil which do not appear above, but which should not be overlooked. Firstly, the elimination of a by-product in the shape of coke ashes from the wind furnace; and secondly, a great saving in labor and personal discomfort to the man who does the melting, which is a point of some importance in a tropical climate.

E. M. HAMILTON.
San Sebastian, Salvador, October 22.

A Curious Occurrence of Copper.

The Editor:

Sir—A copper prospect discovered this summer near the head of Kasaan bay, Prince of Wales island, Alaska, presents some unique features which may be of interest to your readers. The outcrop occupies an irregular ‘hump’ some 50 yards in diameter, rising 25 or 30 ft. above the surrounding country. On the surface this hump looked like an ordinary mass of granular diabase, merging in places into a peridotite. There was no iron rust noticeable, nor any other mineral stain indicating ore beneath, but on breaking into the diabase it was found to be flecked with bornite. At a depth of three or

four feet splendid specimens of solid bornite were found, and the rock was permeated with green carbonate stain. Pyrite and chalcopyrite seem to be wholly absent at the depth so far attained. A sample of hornblende and bornite assayed \$8.20 in gold, with a copper content of 2½%. There are none of the usual gangue minerals formed by alteration of the country rock by mineral solutions. There is no vein, fault, or shear-zone, nor any contact with another formation that can be discovered on the surface. It is up to the economic geologist to tell us how it happened.

W. W. RUSH.
Ketchikan, Alaska, November 3.

Who Is a Mining Engineer?

The Editor:

Sir—A contribution in your issue of October 27, under the foregoing caption, looks to me like the re-opening of a discussion which occurred a few years ago between myself and another who criticised the use of the letters E. M. annexed to my name in a newspaper card.

It is not my purpose to defend my use of the abbreviation in question. That usage now seems to me to have been somewhat ill-advised and amateurish. It is true that I had graduated from a practical mining school of excellent standing, and had supplemented the knowledge there gained with a correspondence course in metal mining; I was familiar with the use of instruments, had a fair insight into mining geology, and could make assays and qualitative determinations. But I had not presided over the operations of any mine, and my standing was not, therefore, properly defined by the term ‘mining engineer.’ The crux of the discussion, however, lay in the claim made by my opponent that the use of the letters E. M. is permissible only to one who has taken a college degree. This contention I excepted then, as I do now.

While I find fault with no college man for being jealous of whatever distinction he may have acquired in the way of titles, I think there is such a thing as being over-punctilious about non-essentials. It seems preposterous, and a trifle caddish, that college men should arrogate to themselves a monopoly of the letters of an authorized abbreviation. But perhaps the more uncouth of us may yet be entertained with a monograph on ‘The Etiquette of Engineering.’

Permit me to subscribe myself, with, I trust, becoming modesty, merely

A STUDENT OF MINING.
Redding, Cal., November 3.

The Editor:

Sir—I have been reading, with much interest, the discussion going on of late in the columns of your valuable Journal referring to that much mooted question of ‘Who is a mining engineer?’ In pondering over what I have read, in the discussions mentioned, it seems to me this question should be changed to read thus: ‘What are the duties of a mining engineer?’ After settling this latter point, the answer to the former question would manifestly be: He who is skilled and proficient in the prescribed duties of a mining engineer.

Personally I have for many years thought that the term ‘mining engineer,’ like the term ‘mining,’ is generally used altogether in too broad a sense, and to embody in its functions requirements that are often foreign to mining, and to embrace duties which should not be included in the profession. According to my way of looking at the question of ‘What are the duties of a mining engineer?’ I should say his first duty is to attend strictly to the business of operating underground or surface mines along the lines of the best-known economy and up-to-date methods. And in this vocation, if the would-be engineer happens to be a manager or superintendent of a large

mine, in order to merit the name 'mining engineer,' he should be competent to fill the position of any man working under him, from common miner to surveyor, assayer, chemist, geologist, mechanical engineer; and more, he should be competent both from practical experience and education to intelligently and effectively direct each and every one of his subordinates in their respective duties.

I may be accused of having imposed rather too much upon the duties of the would-be mining engineer. Well then, if such accusations follow, I would suggest that if the man who is most likely to find himself weak in these requirements, would be properly called a mining engineer, he had better leave the smelting centres, or the locality of other ore reduction works and buy a ticket to some live mining camp where the duties of a mining engineer can be learnt and become a student of the things he ought to know, let other business alone, and confine himself strictly to mining pursuits, then he may hope to become proficient in the duties of a mining engineer as above prescribed. My conclusion therefore is: Any man whose efficiency and proficiency in mining practice and mining technology can fully meet these requirements anywhere and everywhere, is, in the strictest sense of the term, a mining engineer. But no matter how old or how young he may be in the business, how much or how little education he may have, or from what school, or no school, he may be a graduate, he is not a mining engineer if he is not equal to all this and more.

G. W. MILLER.

Denver, November 5, 1906.

The Editor:

Sir—In the current discussion on this subject your correspondents have supplied an abundance of comment, criticism and comparisons of excellent quality, which, if prone to dwell on the threadbare idea of a union of theory and practice, technical knowledge and common sense, are illuminating and interesting. It seems to me, however, that in their enthusiastic support of this idea, nearly all your contributors have been led to expect too much of a degree or professional title. In nearly every case, the definition given makes a 'mining engineer' a paragon of ability and rectitude, whereas, as pointed out by Mr. G. C. Hewett, in your issue of October 6, there are bound to be more or less incapable men, and dishonest men, to whom the title cannot be denied. Why then expect the title, whether conferred as a degree or assumed by self-educated men, to tell us if a man is worthy to bear it? Very few, if any, titles are so descriptive.

It seems entirely practicable for a degree to certify to a given proficiency in the occupations whose basis is in greater part academical, such as a professor of the classics, or even a chemist, but such can never be the case for a profession like that of mining engineering of which an integral part is business experience and a broad understanding of human relationships. As soon could we expect that the diploma of a business college would stamp the graduate as a 'business man,' or that a title of 'financier' could with sharp-drawn lines be applied to the few who are entitled to this broad, yet in a real sense, distinctive designation.

The real need seems to be for a differentiation of titles for the technically educated and graduated mining engineer, and for the man who is engaged in the profession without that aid. 'Mining Engineer,' in your issue of October 27, has been the first to make a suggestion along this line, but is not his plan of having the initials 'E. M.' designate a college man, and the words 'Mining Engineer' one who has had experience whether from a college or not, too arbitrary and too much in need of an accompanying explanation to gain favor, especially considering

the long-established use of both these terms in other ways?

I submit that such a designation should be self-explanatory, and with this in mind, propose that college men shall sign themselves 'Graduate Mining Engineer,' or in abbreviation, 'Grad. E. M.' This leaves the term 'Mining Engineer' for the use of such as choose to apply it, but none could use the other without deliberate false intent, unless they were really graduates. It is true that this might include those who had taken a six-weeks' course in assaying, and had been 'graduated' from the institution giving it, but such mis-applications can never be prevented until all the men are honest, or we have not only a pure-food but a pure-man law, requiring each to be truthfully labeled.

Given the co-operation of alumni of recognized schools of mines, the authorities of these schools, and the engineering societies, this appellation could be made distinctive and valuable, and its use would imply no disparagement to the many superior men who could not qualify for a share in it. It is short, euphonious, unpretentious, distinctive, equally suited to the young graduate and the alumnus of '75 (whom it is not practicable, as before pointed out, to differentiate by titles), and I believe would serve a useful purpose.

WM. MAGENAU.

Gomez Palacio, Mexico, November 14.

The Editor:

Sir—Whence "the divinity which doth hedge" a mining engineer—that he is not to be rated by the same standards as engineers in other lines and judged by the same tribunal?

Whether the above fragment from Shakespeare has been correctly quoted or not, I make no doubt that it will recall to the mind of every reader of this journal their first thought, namely: Who else can be a reliable mining engineer except the man who possesses the knowledge, both technical and practical, necessary to fit him for the profession? And who but those who hire the services of mining engineers are to decide whether he has or has not that knowledge? No more do I doubt that a majority of the readers are of my own mind regarding the author of the 'Viator' letter. Viator may have traveled up and down the world, and have a perfect right to assume such a *nom de plume*, but it seems that few, if any, of the most important facts of mining history ever came within the range of his observation or hearing, else he never would have voiced the opinion that only those who have first received a college or mining school diploma can ever become mining engineers—"the real thing." It occurs to me that our friend Viator has some ideas in common with the element I have already spoken of, and both he and they might be better qualified to give opinions on 'mining engineers' if they would only post themselves concerning the 'doings' of some of the 'big gun' mining engineers of both present and past.

Can anybody give a sensible reason why there should not be good, bad, and indifferent mining engineers, just as there are bad plumbers, worse plumbers, and plumbers whose degree the English language furnishes no fitting term for—"road agent" being the nearest approach to it?

"By their fruits ye shall know them" is a precept that has stood the wear and tear of many centuries. This principle has been the rule by which the true worth of mankind has been gauged since the dawn of creation and will remain so until the end of time. It has no rewards for the unworthy. It applies to bricklayer and mining engineer alike—without favor or discrimination.

I take it for granted that anyone who has some understanding of the mining business believes that a man who first receives a thorough technical education and then a

thorough practical one afterward should, and often does, make the best mining engineer, but in a great majority of cases he is a lamentable failure—simply because he has not brains enough to know that his technical schooling only makes it easier for him to *learn* to be a mining engineer than if he had no such rudimentary training.

The last article I read in the discussion was that of Edward W. Ralph in your issue of October 13, and I believe it commends itself to all as being unanswerable. In the preceding issue George J. Bancroft defines a

Movable Distributor Vat Being Discharged Into End Vat, for Percolation.

“mining engineer as being a man skilled in all the principles and in all the practices of the mining business.” According to such a definition there are no mining engineers—“no pole long enough to reach the persimmons.” I rather suspect Mr. Bancroft of joking, but if he really means it, then he has taken an extremely radical position, and an altogether untenable one, for no part of the mining business has yet been reduced to an exact science—no engineer has yet reached the ultimate in any branch of it—nor can any man, in one lifetime, be sufficiently “skilled” in all the branches to warrant him in thinking that he knows all there is worth knowing about it.

Whatever may be the purpose back of the question which is the subject of this discussion, it should be considered on its merits alone, if considered at all, because there are too many intelligent mining men entitled to a say as to who are real mining engineers to permit any guild of the profession to bar from it all or any competent man simply because he did not happen to be fortunate enough to build on the guild's prescribed foundation. Let us choose but one illustration: Who will dispute the late Marcus Daly's right to the title of ‘mining engineer?’ Although he did not have the advantage of a preparatory college course, what mining engineer of the college type ever equalled his achievements?

“A fair field and no favor” is all that is asked by the man who has gained his knowledge of the mining business by hard knocks in the practical field. If he has not had time or opportunity to properly equip himself with the necessary technical part he can *hire* that, just as 95% of the mining school graduates have to do with regard to the practical part.

E. E. WANN.

Kingstone Mountain, Cal., October 30.

[This discussion is now closed. It is reviewed at length on a preceding page.—Editor.]

A Distributor Vat.

To Mr. Gerald Browne we owe the accompanying illustrations of a movable distributor vat in a cyanide plant at the Sons of Gwalia mine, Western Australia. These distributor vats run on three rails and are moved by a windlass-handle on a worm-gear arrangement connected with one three-wheel axle. Two men can move a vat either full or empty, and in this way it can be filled or discharged above any vat required. There are two lines of vats and two movable distributors. When one is filled it is dried by the vacuum-pump in the usual way and the material is discharged—ready for percolation and well aired—into any vat below. The simplicity of the arrangement is obvious.

The Mineral Output of Ontario.

The Bureau of Mines has just issued a statement of the output of the metalliferous mines and works of the Province for the nine months ended September 30, as follows:

	Quantity.	Value.
Gold, oz.....	2,015	\$34,377
Silver, oz.....	2,542,827	1,603,554
Cobalt, tons.....	138	110,400
Nickel, tons.....	8,037	2,856,233
Copper, tons.....	3,900	600,000
Iron ore, tons.....	93,159	117,466
Pig iron, tons.....	208,094	3,194,206
Steel, tons.....	123,257	3,069,070
Zinc, tons.....	300	4,500
Arsenic, tons.....	691	13,530

All the silver, cobalt, and arsenic came from the Cobalt district, the two latter items being to some extent estimated. The nickel and copper came principally from Sudbury, and the iron ore from the Helen mine, Michipicoten. This is reckoned over again in the items of pig iron and steel, which also include imported raw material. The Cobalt ore mined, but not shipped, during the

Movable Distributor, Unfinished.

period covered by the returns, amounting to 893 tons, is not included.

KUNTZITE is a beautiful variety of spodumene that is much prized as a gem stone. In color it has a unique peach-blossom tint, and also possesses great brilliancy. These are its only recommendations, for it is not hard enough to wear well and has a well-marked cleavage. The value of such gemstones depends almost entirely on fashion and it is accordingly a variable quantity. San Diego county produces this beautiful mineral, where it occurs associated with tourmaline and lepidolite, a lithia mica.

Three Weeks in Mexico.---XII.**The Chemistry of the Patio Process.**

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

The *patio* has been used on a large scale and continuously since 1557, therefore it is probable that a great many have attempted, at various times, to investigate the process; nevertheless, few have been bold enough to publish the results of their investigations. In offering a few notes, it is with the hope, mainly, of helping the younger students in our profession.

The right amount of bluestone¹ is important, for if it be insufficient, the copper sulphate is converted into the sub-oxide, which reacts on the mercury so as to sicken it, covering it with a film. The bluestone consists of the sulphate of iron as well as copper, for it is formed by the roasting of chalcopyrite; these sulphates react on the sodium chloride so as to liberate hydrochloric acid,

upon the silver mineral, transforming it to a chloride. A subsequent reaction with the hydrated oxides liberates the silver and hands it over to the mercury, for amalgamation. The copper sulphate acts as a carrier of oxygen and the presence of it is important to preserve the mercury in a metallic state.

The old theory, to be found in most text-books, was that after the cupric chloride was formed, a reaction with the silver sulphide mineral, in the presence of air, yielded cuprous chloride and argentic chloride, the argentic chloride coming in contact with the mercury, so as to form an amalgam, together with mercurous chloride, thus:

It is a complex bit of chemistry, rendered obscure by the lack of accurate data. The *patio* process is rarely

The Patio Process. Mules Mixing the Charge.

which, according to Ortega,² first forms cupric chloride and then, in the presence of mercury, cuprous chloride and mercurous chloride. The cuprous chloride absorbs oxygen and then reduces the silver sulphide in the ore, with the formation of mercuric sulphate and the liberation of the silver. Thus:

On being liberated, the silver immediately forms an amalgam with the excess of mercury.

On the other hand Bustamente³ claims that the iron sulphate in the *magistral* is essential, the role of the copper being, in many respects, subordinate, although necessary, to the iron. According to his explanation, ferric chloride is formed; this, on being reduced to a lower chloride, releases chlorine, which, while nascent, acts

checked by systematic analyses and assays, so that, despite the three centuries and a half during which it has been used in Mexico, there is but little evidence available. One or two points stand out clearly. If silver chloride be formed directly from the action of the chlorine liberated from the salt, and if this be a necessary chemical stage, why is it that ore containing hornsilver or natural silver chloride cannot be treated successfully by this method? If copper sulphate be the sole active agent in the *magistral*, why is it that the pure copper sulphate gives such poor results? If there is no direct chlorination of the silver, why is so much salt required? The first two queries have been answered; the last can be explained on the ground that the brine serves as a solvent for the cuprous chloride, rendering it more active as a carrier of oxygen.

Humboldt makes several interesting observations⁴ on the process of amalgamation in the *patio*, as carried out during his visit to Mexico, a hundred years ago:

"The process invented by the miner of Pachuca is one

¹ *Magistral*, an impure mixture of copper and iron sulphate was formerly employed. Bluestone, commercial copper sulphate, has replaced it in practice.

² The *Patio Process for Amalgamation of Silver Ores*, by Manuel Valero Ortega. *Trans. Amer. Inst. Min. Eng.*, Vol. XXXII, pp. 274-282.

³ A Study of Amalgamation Methods, etc., by Miguel Bustamente, Jr. *Trans. Amer. Inst. Min. Eng.*, Vol. XXXII, p. 489.

⁴ Political Essay on the Kingdom of New Spain. Black's translation. Vol. III, Book IV, p. 288.

of those chemical operations, which for centuries have been practised with a certain degree of success, notwithstanding the persons who extract silver from minerals by means of mercury, have not the smallest acquaintance either of the nature of the substances employed, or the particular mode of their action. The *azogueros* (or amalgamators) speak of a mass of minerals as of an organized body, of which they augment or diminish the natural heat. Like physicians who in ages of barbarism, divided all ailments and all remedies into two classes, hot and cold, the *azogueros* see nothing in minerals, but substances which must be heated by sulphates if they are too cold, or cooled by alkalis if too warm. The custom which was already introduced in the time of Pliny, of rubbing metals with salt, before applying the amalgam of gold, has undoubtedly given rise to the use of muriate of soda in the process of Mexican amalgamation. This salt, according to the accounts of the *azogueros*, serves to clean and to unskin the silver, which is enveloped with sulphur, arsenic, and antimony, as with a skin (*tililla* or *capuz*), whose presence prevents the immediate contact of the silver with the mercury. The action of this last metal is rendered more energetic by the sulphates with which the mass is heated; and it is even probable that Medina only employed simultaneously the sulphate of iron and copper and the muriate of soda, because he discovered in these first attempts, that salt was only favorable to the process in the minerals which contained decomposed pyrites. Without having any clear idea of the action of the sulphates on the muriate of soda, he endeavored to recompense (*refaire*) the minerals, that is, to add *magistral*, to those which the miner considers as not vitriolic."

The 'hot' and 'cold' condition—called *calentura*, or fever, and *frio*,—are untechnical references to oxidation and reduction, the sulphates contributing oxygen as fuel to the chemical reactions while the alkali of the lime, ashes, or cement copper employed to doctor a 'hot' *torta*, neutralizes any excess of acid sulphate. The idea that the silver of the argentite was coated with sulphur, which had to be removed to permit of contact with mercury, illustrates the ignorance of what constitutes a chemical compound. The sodium sulphate is formed by the reaction between the "muriate of soda" or common salt and the copper sulphate, so that the addition of it simply anticipated a reaction which would follow from the use of *magistral* and the mention of "decomposed pyrites" suggests the agency of iron sulphate in the *patio* process, an agency the exact working of which is yet a subject for debate among metallurgists.

Further on, he explains how, by the leaden look of the mercury they inferred the commencement of chemical action; when a fine gray powder is separated from it which sticks to the fingers, they say the paste is too 'hot' and they 'cool' it by adding lime. If it preserves its metallic lustre, or is covered with a reddish pellicle or film, if it does not appear to act upon the mass, the amalgamation is considered too 'cold' and they endeavor to 'heat' it (*calentar*) by mixing *magistral*.

The "leaden look of the mercury" is due to excess of copper sulphate, with formation of flouring mercuric chloride, which, in presence of sunlight and organic matter (such as the droppings of the horses or mules that trample the *torta*), is converted into oxide; this is almost insoluble in the brine, formed by the excess of salt, and in consequence it is apt to be lost in the *torta* when it is finally discharged after treatment. When the *torta* is cold, the mercury is apt to show 'flouring'; it is in minute globules that do not coalesce, being coated with a reddish film of copper sub-oxide, because there is not enough of the copper sulphate present to generate chlo-

rine from the salt, so as to form cuprous chloride.

At first the charge was mixed by the treading of a number of bare-footed workmen, but in 1783 Juan Comejo brought, from Peru, the idea of using mules and the Government granted him a privilege for it. This decreased the expenses of the process by one quarter.

Then Humboldt continues: "It has been long proposed to cover the surface on which the pastes repose with plates of iron and copper instead of flags; and it has been endeavored to stir the mass by working it with ploughs of which the share and coulter should be made of the metals mentioned, but the mules suffered too much from this work, the *schlich* (slime) forming a thick and by no means ductile paste." Finally, he concludes: "The process invented by Medina possesses the great advantage of simplicity; it requires no construction of edifices, no combustibles, no machines, and almost no impelling force. With mercury and a few mules to move the *arastras*, we may, by means of amalgamation *por patio*, extract the silver from all the meagre minerals near the pit from which they are taken in the midst of a desert, provided the surface be sufficiently smooth to admit of the establishment of the *tortas*; but this process has also the great disadvantage of being slow and causing an enormous waste of mercury."

How great this waste of mercury was, it is difficult to realize today when the old tailing has been washed by several generations of patient *peones*, or else scattered abroad by the torrential rains of the tropics and the dry wind of the high plateau. They used eight parts of mercury to one of silver. At El Oro the mill with 100 stamps was run for six years without the purchase of a single flask of quicksilver. The tailing heap of the old *hacienda*—built 30 years ago—gave all the mercury wanted. In cyaniding the tailing, the mercury was dissolved, to be precipitated in the zinc-boxes with the gold. The precipitate was retorted in order to drive off the water and the quicksilver. Out of a retort of 1,000 lb. there would be obtained 150 lb., or two flasks of quicksilver. Another suggestive incident may be mentioned. Nearly two years ago, when the mechanical ploughs (*repasadoras*) were installed at the Loreto mill, a cement floor was laid down, and in excavating for this purpose a big find of quicksilver was made, the earth being saturated with it. It is said that mercury worth more than 30,000 pesos was obtained.

As Humboldt said, the *patio* was successful despite the ignorance of any chemical reactions involved. It is only recently, when the process is being discarded for more effective methods, that the chemistry of it has been investigated intelligently. As used for 350 years it was an empirical process, regulated by the experience obtained with the particular ores of each district.

The *patio* was invented when men, horses, and time were cheap, when there was no haste to realize on the ore in the mine. And this spirit survives; when I asked one of the Mexican engineers why they did not exploit a certain rich mine on a larger scale, he said that the shareholders did not care to rush the production because they feared the mine might be worked out too soon. This is the European idea of fifty years ago; the opposite of it is the American notion that it is best to gut a mine expeditiously and make the maximum money in the minimum time. Both extremes are extravagant.

NOTHING great in science has ever been done by men, whatever their powers, in whom the divine afflatus of the truthseeker was wanting. Men of moderate capacity have done great things because it animated them; and men of great natural gifts have failed, absolutely or relatively, because they lacked this one thing needful.

Ventilation in Deep Mines.

In a recent letter from our Melbourne correspondent, reference was made to the enquiry into the ventilation of the deep mines at Bendigo. A careful investigation was made by Mr. Walter Summons, a physician, the cost being defrayed by the trustees of one of the late owners of *The Argus*, the leading newspaper of Australia. The workings examined varied in depth from 885 ft. to 4,236 ft. Tabulated, some of the data were :

MINE	Depth—Feet	Height—Feet	Temperature Degrees F.	Water Vapor Per Cent.	Carbon Dioxide Per Cent.
Suffolk. Plat	1,674		88	95	
" Ralse		70	85	97	0.465
Lansell's 180. Plat	3,300		87	95	
Victoria Quartz. Plat	4,010		87	98	
" Bottom of shaft	4,254		88	94	0.212
New Chum Railway. Plat	3,856		92	97	0.139
" Bottom of shaft	4,236		95	99	0.203

During the period devoted to the investigation, from midsummer to the depth of winter, the temperature at surface varied 40°, but that of the mines was practically unchanged. In the Suffolk, the use of a spray of water and air, at high pressure, through an atomizer, decreased the carbon dioxide from 0.465 to 0.165% within three hours, the temperature falling from 88 to 77°. In sinking the New Chum Railway shaft the conditions became so oppressive that the men were expected to work on six-hour shifts. At the West Berry Consols, an alluvial (deep lead) mine, the air at a depth of 420 ft. showed 0.524% CO₂ at the plat. Ventilation is promoted by a pair of No. 4 Root blowers. The workings are wet and there is no dust, the large quantity of carbon dioxide being due to organic matter in the gravel. Mr. Summons emphasizes the bad conditions accompanying work in raises; as the holes are drilled upward, the men work in a cloud of dust, and the only ventilation is from the exhaust air of the drill. A jet of air or a water spray both ameliorated the worst conditions. In the deepest mines, ventilation is sadly defective. For example, in the New Chum Railway, air from the 3,856-ft. plat contained 0.139% of carbonic acid, while a sample from the bottom of the shaft, 4,236 ft. down, showed 0.203%. These are the only two places in the mine where the men are at present working. "In this mine during my visit," writes Mr. Summons, "the men went down for eight hours, but only worked in the shaft 30 minutes at a time, while the second pair were 'cooling' in the plat. Since then they have worked in shifts of only six hours. Examination of the men in the 3,856-ft. plat, at 'crib' time (after resting), showed their pulse rate per minute to be 88, 92, 96, 104, 108, 108, 112, and their temperature to be 101°, 100.7°, 100.5°, 100°, 99.2°, while my own rose from 98.4° to 99.5 in 30 minutes, taking no exercise whatever in that time. Here the ground was wet, and the air practically saturated with watery vapor, while the temperature of the plat was 90°, and that of the bottom of the shaft was 95°. One great redeeming feature of this mine is the absence of dust. The men were sallow and sickly looking; while, from out of the few men employed in it during my six months' investigation, I examined two, and both were tuberculous, their sputum teeming with tubercle bacilli. In this case neglect of carrying down winzes along with the shaft has had, no doubt, a good deal to do with the defective ventilation, and now it is the intention to sink the shaft 4,300 ft.—that is, nearly 450 ft. from the plat—before another cross-cut is driven. In the Hercules and Energetic mine the amount of carbonic acid in a drift at a depth of 480 ft., and 200 ft. from the shaft, was found to be 0.35%, and in the intermediate,

500-ft. level—not directly connected with the shaft—the percentage was 0.46. In this latter level the men were accustomed to have their crib, and much waste food was carelessly thrown about, even though the manager had provided a box for it. The bread was mouldy and rotten, giving a musty sickening odor to the place. The large percentage of carbonic acid gas resulted to a certain extent from the decaying matter, but to a greater degree was due to insufficient ventilation."

Mr. Summons states that the solid matter that constitutes the dust consists of minute particles of quartz, arising from the breaking of ore. In winzes, raises, and dead ends generally the dust is worst. It ranges from 560,000 to 800,000 particles per cubic centimetre. While the air of large cities contains dust, it is only breathed for a short time, at intervals, whereas the miners breathe it during a whole shift of eight hours. Another distinction is to be found in the character of the dust. In cities it is the carbonaceous matter from chimneys and the like, which is almost inert when breathed; whereas the dust in a quartz mine is hard silica with jagged edges that cut the tissue of the lungs, producing fibrosis. On the Rand they call it 'silicosis.' It induces tuberculosis, and on this subject Mr. Summons was also emphatic, for he lays stress on the danger to the workmen of their breathing the air of those thus afflicted.

The temperature of these deep mines is naturally high. It increases one degree for every 70 ft. of additional depth. The highest reading was obtained from water issuing from a crevice in the Victoria Quartz mine, at 4,200 ft. below surface, or 3,700 ft. below sea-level, where the thermometer registered 114° F. Heat is derived from the result of chemical action due to (a) the persons present, (b) light and explosives, (c) the exposed rock surfaces, and (d) the compression of the air as it descends the shaft, through increase in the barometric pressure. Though the temperature of the deep mines is higher than that of the shallower ones, exceptions are found, especially where the shaft is downcast and the air has not been in contact with the rock sufficiently long for a mean temperature to be attained. Nevertheless, where the air has traveled some distance in and around the workings a stationary temperature is reached, this being clearly shown in the case of the Victoria Quartz and Lansell's 180 mine. After pointing out that at deep levels air fresh from the surface has a powerful cooling effect, Mr. Summons draws attention to the fact that in time a point is reached when the gain and loss counterbalance one another. To the temperature and the humidity combined is due the languor felt by the men at work, and also the inability to perform sustained work.

In the saturated air the miners perspire continuously, but the perspiration does not evaporate, so the skin is always moist. This is not healthy and it causes the body temperature to rise. The men have a feeling of exhaustion and discomfort even when not engaged in hard work. From an economic point of view, it is a mistake to perform labor under such conditions. No additional wage should carry weight, for, apart from the inhumanity of it, such a concession does not meet the problem, which will become increasingly burdensome as the mines are deepened. "It is not knowledge," says Mr. Summons, "but performance that will rectify matters." As the properties at Bendigo are extremely small, it is impracticable to sink two shafts, but connections can be made with adjoining mines, and winzes should be sunk as the shaft is going down, with connections through cross-cuts at regular intervals of not less than 100 ft. These will not be without value in prospecting the ground between the larger saddles. In raises, the box or three-compartment system should be employed, and in dead ends the air-jet machine ought to be used.

Methods of Mining at Ely, Nevada.

Written for the MINING AND SCIENTIFIC PRESS
By C. EVERARD ARNOLD.

On account of the low content of the ore in the Nevada Consolidated Copper Co.'s property, it is imperative that the ore shall be mined and treated in large quantities and at the lowest possible cost, in order to ensure profitable working.

The white porphyritic rock which carries the copper is fortunately very much decomposed, soft, and easily mined, and in accordance with the opinion of J. Parke Channing (who reported on the company's holdings) that the methods of mining employed in working the wide hematite deposits of the Mesabi Range could not be successfully applied here, the company has decided to follow the scheme used by the Oliver Iron Mining Co. in their Pioneer mine at Ely, Minnesota. This scheme, of which a description is given later on, is being carried out under the supervision of Capt. Richard Toms, who, for many years, was mine captain at the Chandler and Pioneer properties.

As regards the present state of mine development, all operations have ceased at the Eureka property (which

by 6 ft.; this will enable the loaded timber-truck to be run onto the cage, lowered, and run right into the workings, thus avoiding the troubles incidental to lowering heavy timbers when they have to be loaded on the cage at the surface and transferred at the station to the truck.

After connecting the two shafts, a large ore-pocket will be built off the Star-Pointer shaft, under the 500-ft. level, and the level continued on the west side of the shaft far enough for the accommodation of a train of cars. Fig. 2 shows a plan of portion of the proposed workings on the 500-ft. or main level, illustrating the manner in which the orebody is to be divided up into a number of pillars, approximately 50 by 70 ft. each, by the intersections of the drifts and cross-cuts that comprise part of the main level. This level is being cut large enough to allow 8 ft. clear between cap and sill, 6 ft. 2 in. between tops, and 8 ft. between bottoms of posts.

Electric traction is to be used underground and the reason for the number of turns in the drifts and cross-cuts is that the tracks will contain as many stationary switches as possible, and with this arrangement the process of running the ore out to the station will be as follows: Suppose, for example, that there are ore-chutes at A and B, in front of which is a train of loaded cars;

Fig. 1. Plan of Timber-set for Star-Pointer Shaft.

lies six miles west of Ely), and on account of the soft nature, width, and proximity to the surface of the orebody, it is extremely probable that steam-shovels will be employed in mining it. At the Ruth mine (which is 1½ miles east of the Eureka mine) all energies are being put forward to connect the Ruth shaft with the new Star-Pointer shaft. The Ruth shaft pitches north at an angle of 42°, and the connection is being made by means of a level running west, started at a depth of 500 ft. on the incline. This level has been driven through 950 ft., and after having gone 2,300 ft. it is expected to tap the Star-Pointer shaft, which is vertical, at a depth of 342 ft. A plan of a timber set for this shaft is shown in Fig. 1; the shaft has been sunk 230 ft., striking the orebody at a depth of 150 ft. All drilling is done by hand, and working three eight-hour shifts with five men per shift, the shaft was sunk and timbered 72 ft. during the month of September, all broken rock being hoisted after every round before drilling was re-commenced. No water has been encountered as yet either in this shaft or in the 500-ft. level of the Ruth.

All the hoisting of ore is to be done through this shaft, which will be equipped with a steel head-frame and sub-structure, the railroad from the concentrator coming right up to the storage bins which are now in course of erection, their capacity for the present to be 3,742 tons. On a platform above these bins will be erected two No. 7½ Gates gyratory crushers, a 30-in. belt-conveyor distributing the crushed rock into the bins. It will be noticed in Fig. 1 that the shaft has one very large compartment, 5 ft. 6 in.

and that a train of empty cars is wanted at chutes C and D. The locomotive leaves the station with a train of empty cars behind it; running along in the direction indicated by the arrows, it couples onto the train of full cars at chutes A and B, and still pulling the empty train it pushes the full train ahead along the course shown past chutes C and D, where the chute-tender uncouples the empty cars from the locomotive. The journey is then continued, the full cars being pushed along and emptied into the pocket at the station. The locomotive next reverses and pulls the now empty cars behind it, being then ready to perform a similar cycle of operations. Thus the empty cars can be run into, and the full cars run out of, the workings without the inconvenience and loss of time which accompany such switching.

After completion of a series of pillars on the main level, vertical raises will be put up in the pillars at intervals of 25 or 30 ft., and after rising 30 ft. a sub-level will be run directly over the course of the main level below. This system of raises and sub-levels will be continued up to the next main level, thus dividing the ground between the two main levels into a system of pillars that are ready to be caved, the raises having been cribbed up and used as chutes. The caving is to be performed by carrying inclined raises, tributary to the vertical raises, from the four sides and into the centre of a pillar, thus rendering possible the caving of a pillar directly above it, the rock being blasted and caved down into the raises, where it will run straight to the chute-gates on the main level.

It will necessarily be some time before this scheme can

be put into running order, but it will doubtless be completed in time to enable the mine to keep the concentrating and smelting plant supplied, which it is estimated will be in operation by May, 1908, its initial capacity to be 5,000 tons daily, with an approximate ultimate capacity of 15,000 tons.

THE HAILE MINE in South Carolina has been worked more or less continuously since about 1830 and during all that time has been one of the most important mines of the region. In early days leases were given on sections 50 ft. square, and open-cuts were made on these claims by slave labor. This was of course disastrous to systematic, economic mining. The upper, oxidized portions of the orebodies were rich and some of them yielded lumps of gold worth from \$300 to \$500. Except during war time, open cutting was carried on until about 1880, when

Korean Mining Laws.

Among the new regulations recently promulgated are the following:

ARTICLE 4. The boundaries of mining claims shall be limited by straight surface lines extending vertically downward. Their area in the case of coal shall not be less than fifty thousand tsubo, and in the case of other minerals not less than five thousand tsubo; and in neither case shall it exceed a million tsubo. The latter limit may, however, be exceeded in case it is absolutely necessary for the protection of public mining interests or for the amalgamation or division of mining claims.

ARTICLE 7. The Minister of Agriculture, Commerce, and Industry shall have the power to refuse permission for mining, in case he considers such a step to be necessary in the public interest or for any other reason.

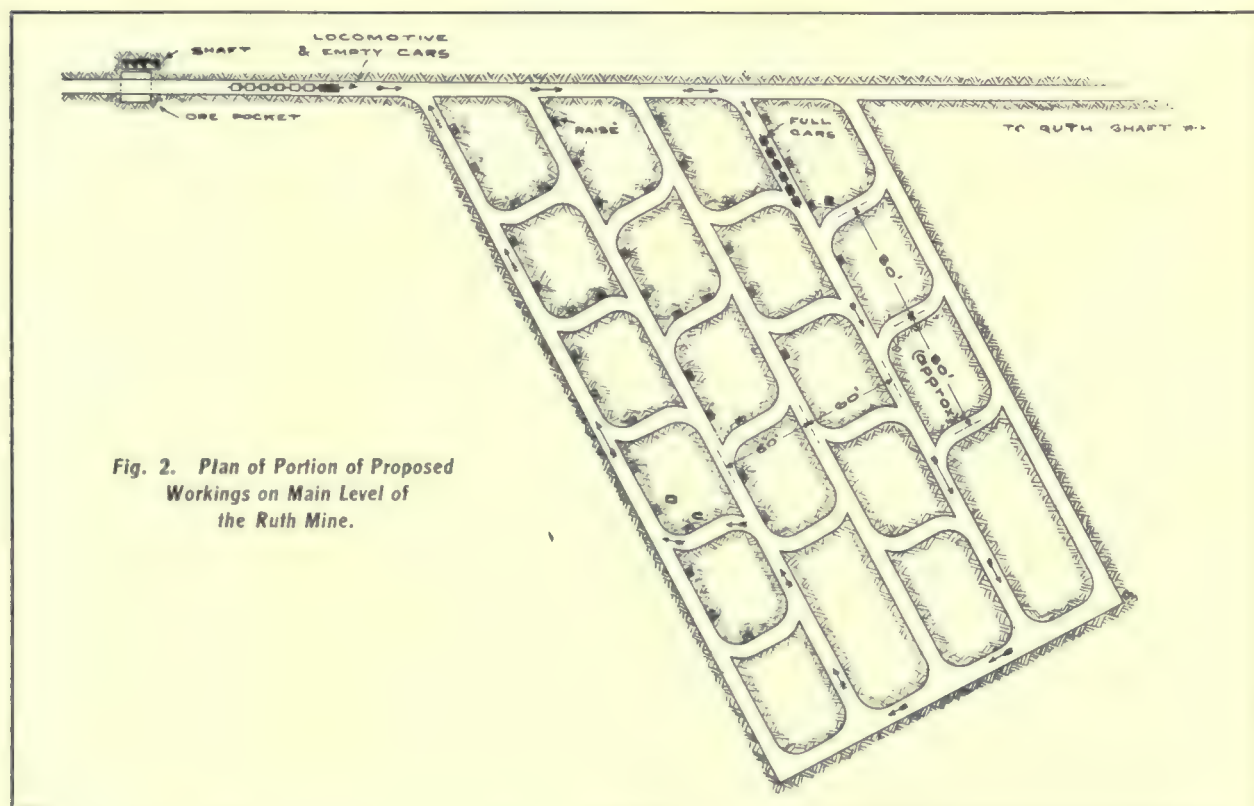

Fig. 2. Plan of Portion of Proposed Workings on Main Level of the Ruth Mine.

actual underground mining was begun and continued up to about four years ago. A return to the open-cut system has been made on a much larger scale than formerly. This mine, said to be the only steady dividend-paying gold mine in the Southern Appalachians, owes its success in recent years very largely to the intelligence and persistent efforts of Capt. Adolph Thies, who for nearly 20 years was its manager. Mr. E. A. Thies, his son and the present manager, is following the same policy.—L. C. Graton, U. S. Geological Survey.

THE London Stock Exchange does not, like the New York Exchange, require daily payment for, and delivery of, the stocks bought or sold upon its floor. Such accounts are settled once a fortnight; their settlement occupies three days, respectively known as 'ticket day,' when the names of buyers and sellers are given up, 'account day' or 'contango day,' when provision is made, if desired, to carry a speculative operation over another fortnight, and 'pay day' or 'settlement day,' when accounts are finally adjusted. What London calls the 'carry-over' is effected by payments of a 'contango' or continuation rate, which varies according to the outside discount market, and the account to be carried over.

ARTICLE 10. No mining right may be sold, assigned, or mortgaged without permission of the Minister of Agriculture, Commerce, and Industry. A mining right may be acquired by inheritance.

ARTICLE 21. The Government shall not be responsible for any damage that may be caused by any measure taken by the Minister of Agriculture, Commerce, and Industry by virtue of the present Law or of the Detailed Regulations for carrying it out.

ARTICLE 27. Inasmuch as the measures to be taken under the present Law and the Detailed Regulations for carrying out the same will in many cases concern foreigners, no such measure shall be decided upon or executed without the previous consent of the Residency General. This stipulation shall also apply with regard to the mines belonging to the Imperial Household Department.

ARTICLE 30. Foreigners who have been granted mining rights and have begun operations in connection therewith before the promulgation of the present Law and are still carrying on such operations, shall observe the provisions hereof in so far as they do not conflict with the terms of the grants made to them.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

It is wholly immaterial in which the various steps required to make a valid location of a mining claim are taken, if all such steps are completed before third persons acquire an interest; and a discovery made after staking and record will inure to the benefit of the locator as of the date of the discovery.

Healey v. Rupp, (Colo.) 86 Pac. 1015.

The notices required by the statute to be given by an applicant for a patent for a mining claim, are held to be in effect to all adverse claimants, who are thereby required to assert their rights by filing an adverse within the 60 days' publication of the application, and unless such adverse is filed within that time it will be conclusively presumed that none exist.

Healey v. Rupp, (Colo.) 86 Pac. 1015.

The dedication of a street to a city does not carry with it the title to or property in mines below the surface; and the grantor or any one purchasing from him may take the ore where the mining does not interfere with the use of the street.

City of Leadville v. Colorado Min. Co., (Colo.) 86 Pac. 1034.

City of Leadville v. Bohn Min. Co., (Colo.) 86 Pac. 1038.

In a contest by adverse claimants over the discovery and location, in a case recently decided by the Supreme Court of Utah the following propositions and points of law were decided: (1) That a discovery of a vein or lode on unoccupied and unappropriated mineral lands of the United States is a pre-requisite to a valid location of a mining claim. (2) That a location based upon a discovery within the limits of an existing and valid location is void. (3) That what has been located once under the law shall not be re-located until the first location has expired, until the rights of the former owner or locator have come to an end, and until in law he has forfeited or abandoned his claim and left the property open for another to take up. Until such abandonment or forfeiture, the ground is not subject to re-location, for it is essential that at the time of the location the ground located should be a part of the public domain. Hence, a re-location on lands actually covered at the time by another valid and subsisting location is void; and this not only against the prior locator, but all the world, because the law allows no such thing to be done. (4) That when forfeiture has been occasioned the claim or mine upon which such failure occurred shall be open to re-location in the same manner as if no location had ever been made, provided that the original locators their heirs or assigns, or legal representatives, have not resumed work upon the claims after failure and before such location. (5) That a location to be good must be good when made, and that each claimant must stand on his own location and can take only what it will give him under the law. These propositions are readily deducible from sections 2319, 2320, 2322, and 2324, Rev. St. U. S., and are supported by decisions from both Federal and State courts, and by text-writers.

Lockhart v. Farrell, (Utah) 86 Pac. 1077

In controversies over mining claims and in adverse proceedings to settle disputed questions of location each party is practically a plaintiff and the burden is on him to show his title. This rule is deduced from the United States statute which provided that if in an adverse suit title to the ground in controversy shall not be established by either party, the jury shall so find, and judgment shall be entered according to the verdict. The object of this statute was said to be, to provide, in the case of a total failure of proof of title for an adjudication, "that neither party was entitled to the property, so that the applicant could not go forward with his proceeding in the Land Office simply because the adverse claimant had failed to make out his case, if he had also failed."

Brown v. Curney, 201 U. S. 184.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The sample from Bodie, Cal. marked S. T., is reddish Quartz coated with earthy limonite.

Rocks from V. G. H. of Cripple Creek, Colo. are gray Feldspar-porphry and black Basalt.

The specimen from W. P. de R. of Coaldale, Nev. is a decomposed volcanic rock. Whether it contains value can only be determined by assay.

The sample from E. J. M. of Pasadena, Cal. is Quartz, with some calcite containing flakes of graphite. The blue crystals on the rock from F. W. P. of Quartzburg, Ida. are Vivianite, the phosphate of iron.

Specimens from Pioneerville, Ida. marked J. M. C. are: No. 1, Rhyolite; No. 2, metamorphosed Rhyolite; No. 3, Mica-diorite; No. 4 and 5, hornblende-biotite Granite; No. 6, Pitchstone; No. 7, Andesite; No. 8, Rhyolite; No. 9, Granite, metamorphosed; No. 10, Rhyolite; No. 11, 12 and 13, altered Rhyolite rocks; No. 14, Granite.

TIN IN SOUTH CAROLINA.—Tin occurs along a narrow belt extending northeastward from the centre of Cherokee county, S. C., across Cleveland and Gaston counties to the centre of Lincoln county, N. C. This belt represents the distribution of pegmatite dikes and in its position is dependent on the general geologic structure of the region. The pegmatite is closely related genetically to the granite and granitic gneiss which occur along this belt and which are sometimes cut by the dikes of pegmatite. Most of the pegmatite bodies are very irregular in extent. Tin is present as the mineral cassiterite, which occurs only as an original or primary constituent of the pegmatite. This mineral is not evenly distributed through the dikes, but is generally segregated or concentrated along certain lines. The orebodies or shoots thus formed generally pitch at a considerable angle and are of small cross-section, but extend indefinitely along the pitch. They are probably irregular in extent, somewhat after the fashion of the dikes in which they occur. The percentage of cassiterite in the ore-shoots may be high in places, but the average value will probably be under five per cent. This ore may be reduced to a concentrate of good quality. The cost of production of the metallic tin ought not to be excessive, but will certainly increase with depth. Placer deposits are unimportant. The necessity of shipping the concentrates to England for reduction is a serious handicap and may prohibit operations which would otherwise be successful. The production of the Carolina tin belt will probably always be very small as compared with the amount of tin consumed in the United States.—L. C. Graton, U. S. Geological Survey.

GARNET SAND is widely distributed throughout California, and occurs in districts altogether barren of valuable mineral, as for instance certain portions of the Coast Range and other sandstone areas. For garnet that has the hardness of the Adirondack mineral, 7.5 to 8, or nearly that of topaz, there is a good demand as an abrasive. The Adirondack garnet occurs in laminated pockets scattered through beds of a compact hornblende-feldspar rock. Sometimes the quality of a garnet may be improved by washing in wide troughs set at a slight angle, using a hoe to mix the sand with rapidly running water. A moderate export business is being done in garnet and garnet paper.

Thermal Activity in its Relation to Veins.

By JAMES PARK.

*Igneous magmas are now admitted by petrologists to contain more or less water, together with many constituents of a hydrous or gaseous character. Hence the fusion of magmas is not believed to be the result of dry heat alone but heat in the presence of water.

According to Arrhenius,¹ water renders the magma more liquid. It has been shown by experiment that magmas which require a temperature of 3,000° F. to produce dry fusion can be fused in the presence of water at 500° F. According to the same distinguished physicist, water in a rock magma acts the part of an acid, liberating free silicic acid and free bases.

The activity of water at high temperatures is very great. Barus² has shown that water heated above 185° C. attacks the silicates composing soft glass with remarkable rapidity; and Lemberg has proved experimentally that water at a temperature 210° C. slowly dissolves anhydrous powdered silicates. It is probable that at great depths the pressure will be sufficient to hold the water in the form of a liquid in a superheated condition.³

It is well known that during and after volcanic eruptions there are emitted enormous volumes of steam, with hydrogen sulphide, sulphur dioxide, carbon dioxide, as well as compounds of chlorine, fluorine, and boron. These gaseous and aqueous emanations come from the same source as the igneous magma, accompany the magma in its ascent, and may possibly be one of the contributing causes of the eruption.

Volcanic phenomena can be studied in many parts of the world, but perhaps nowhere with more advantage than in New Zealand. In the volcanic region of the North Island there are thousands of square miles in which volcanic activity can be seen in every stage and phase; there are active, intermittent, and extinct volcanoes, besides innumerable geysers, fumaroles, and hot springs, active, decadent, and dead. The active and intermittent volcanoes discharge their lavas and fragmentary matter from single pipes, or from lateral vents apparently connected with the main pipe, and from fissure rents. The volcanic eruption at Rotomahana in 1886 was from a fissure rent over six miles in length.⁴ The whole length of the rent was the scene of great activity for some weeks after the first great outburst. The geysers, hot springs, and fumaroles occur in isolated groups, or along a line of fissure which often runs along the floor of a valley or lower flanks of a range of hills. The geysers deposit silicious and calcareous sinters, mostly the former; and the fumaroles yield native sulphur. Everywhere the air is pervaded with the smell of sulphur dioxide. The solfataric action is energetic, waning, or dead. With the latter the vents are closed by crustification. Where the hot springs overflow on the surface, they form thick mushroom-shaped mounds of silica. The silica is sometimes soft and porous, but often hard and chalcedonic. In all cases the hot springs and geysers are grouped around the volcanic vents, and along fissures in lavas near the point of emission. The waters range from strongly alkaline to acid; and at Rotorua alkaline and acid springs exist side by side. The ascending deep-seated waters are strongly alkaline, while the source of the acid waters is the superficial deposit of

pumice which overlies the rhyolite. The pumice contains disseminated marcasite, and where the alkaline waters come in contact with the pyrite they are oxidized and reach the surface either neutral or acid, according to the degree of oxidation.

In the Hauraki gold-mining area, which adjoins the northern end of this volcanic region, the country rock consists of andesitic lava, tuff, and breccia of younger Tertiary age, resting on slaty shale and graywacke of probably Triassic age. The gold-bearing veins traverse both the andesite and tuff, but are only productive in the former. They are fissure-veins; but they do not conform to the usually accepted definition of a true fissure-vein, since they are generally confined to the igneous-rock formation. Near the borders of the andesites the veins are small and unimportant, and generally die out when they reach the underlying basement rock. On the other hand, the larger and more productive veins are grouped around the old vents, and there seems to be no reason why they should not descend to a great depth. In opposition to this view Professor Beck⁵ states that it is inconceivable that mineral deposits could be made from solutions at great depths. The country encasing the ore-veins is altered to a moderately hard gray rock.

In the Thames district the distance between the numerous parallel veins which traverse the goldfield seldom exceeds 200 yards, and in almost every instance the veins are separated from each other by a narrow belt of hard unaltered andesite. These hard 'bars' as the miners term them, possess the same general strike and dip as the veins, and in cross-section present the appearance of lenticular masses. They vary from a few feet to 30 yards in width. The country rock has been found to be altered or propylitized down to a depth of nearly 1,000 ft. below sea-level, which is the greatest depth reached by mining. The propylitization of the andesites is not widespread, but confined to small areas grouped around the old volcanic vents. Away from the eruptive centres the andesites have suffered surface-decomposition, but are not propylitized. The propylitization was apparently effected by the fissures, which are now veins, having served as channels for the circulation of the hot mineral waters. From these fissures the waters acted on the rock on each wall, and where the fissures were near each other the metasomatic processes operating from one fissure met those coming from the other. Where the processes of alteration did not meet, narrow irregular sheet-like masses of unaltered rock—the 'bars'—were left between.

At Waihi and surrounding districts the veins are chiefly composed of chalcedonic quartz, possessing all the characteristics of solfataric origin. Some of the larger lodes can be traced on the surface for a distance of 16,000 ft., but the length of the majority is under 5,000 ft. Besides veins having linear extension, there are many huge mushroom-shaped masses of chalcedonic quartz, closely resembling in form the silicious deposits now forming in the volcanic regions around Rotorua and Lake Taupo.

At Kuaotunu and Great Barrier island there are many mushroom-shaped deposits of chalcedonic quartz of great size, in some cases covering thousands of acres. At Kuaotunu they are more or less circular in shape, and seldom exceed 20 ft. in thickness. At Great Barrier island the largest deposit is of an unusual character.⁶ It is nearly two miles long, half a mile wide, and from 50 to 700 ft. thick. The pipe is completely filled with mineral matter. It has been intersected in four mines in a distance of a mile, and opened up by levels for many hundreds of yards. It varies from 12 to 40 ft. in width, and is filled with dense banded chalcedonic quartz, in

which iron and silver sulphides are sparingly distributed. The evidence furnished by the mine-workings implies that the overlying mushroom or umbrella of quartz was deposited on the surface from thermal water issuing from a long fissure in the andesite.

The molybdenite deposits at Jeff's Camp, in the Hodgkinson Goldfield, in Queensland, are described by W. E. Cameron⁷ as roughly circular or oval-shaped outcrops of quartz, or 'blows,' carrying wolfram and native bismuth. The 'blows,' when followed down develop into irregular pipe-shaped masses surrounded on all sides by granite, which is the country rock. When the quartz is extracted there remain only empty pipes or vents. These pipe-like orebodies possess a peculiar genetic interest. They appear to closely resemble the silicious pipes formed in rhyolite by the hot springs in the Rotorua volcanic region and the mushroom-shaped quartz 'blows' at Kuaotunu.

There are near Waihi, in New Zealand, several massive deposits of chalcidonic quartz which are stated by Rutley to be replacements of the andesitic country rock⁸. A similar replacement of andesite by silica is described by Spurr as occurring at Monte Cristo district in Washington.⁹ He mentions that the silicification has proceeded until most of the rock is made up of quartz, which, he says, varies from coarsely to finely crystalline in structure, and contains sulphides, chiefly blende, pyrite, and chalcopyrite. Spurr continues, "Thus we have a complete and gradual transition from andesite to a sulphide ore with quartz gangue, by the progressive replacement of the original materials by silica and metallic sulphides."

In 1894 and 1896 I made an exhaustive examination of the Hauraki andesites for gold and silver. The samples subjected to examination were selected by myself *in situ*. The analyses were conducted by the cyanide test, on samples ranging from two to five pounds. The pulverized material was leached in glass jars with a 0.3% aqueous solution of pure potassium cyanide for 72 hours. The solutions and washings were evaporated, fluxed with a little pure litharge and borax, and the resulting button of lead cupelled. Simultaneous tests were made so as to check the purity of the litharge and fluxes. All the andesites examined were found to contain gold at the rate of 1 to 1.5 gr. per ton, and silver varying from 3 to 30 gr. per ton of rock. The augite-andesite, at 3,000 ft. from the mouth of the Moanataiari tunnel, contained 1½ gr. gold and 3 gr. silver per ton; and the hypersthene-augite-andesite, from the waterfall in Waiotahi creek, near the Fame & Fortune mine, 1½ gr. gold and 30 gr. silver.¹⁰

A petrological examination¹¹ of the rocks showed that the feldspars and pyroxenes sometimes showed signs of alteration. The samples were selected from the least-altered rocks obtainable, and in no case did they contain visible pyrites.

The evidence is by no means conclusive that the gold and silver are primary constituents. Whatever the source of the gold may be, I am inclined to agree with Percy Morgan¹² that the quantity of gold and silver in the veins is too great to be accounted for by the traces existing in the andesite.

J. R. Don,¹³ made an interesting examination for the

presence of gold in the andesites and propylites of the Thames Goldfield. He states that his tests were made upon the concentrate obtained from large samples by the method of crucible fire-assay. His results, in the case of the unaltered andesites, were negative; from which he concluded that these rocks contained no gold. The question that will naturally suggest itself to the mind of the metallurgical chemist, accustomed to the estimation of infinitesimal quantities of gold in cyanide solutions and residues, will be, is the method of crucible or pot-assay capable of sufficient refinement to indicate the presence of gold in the proportion of a grain or two to the ton of rock?

My early tests of the Hauraki andesites in 1894 were made by the crucible-assay method. The results, however, were often discordant and unsatisfactory, chiefly on account of the many sources of possible error inherent to the method—errors that it was found impossible entirely to eliminate. Believing that trustworthy results could not be obtained by the pot-assay, I adopted a method of leaching the pulverized rock with dilute solutions of potassium cyanide. By this process larger samples could be tested than by fire assay, and the possible sources of error were reduced to a minimum. The crucible assay is clumsy, laborious, and, in my experience, incapable of the refinement required for the estimation of minute traces of gold even in the hands of the most skillful manipulator.

Luther Wagoner,¹⁴ of San Francisco, who in 1902 made a number of tests for gold and silver in sea-sediments, sandstones, syenite, granite, basalt, diabase, etc., by the cyanide method used by me in 1894 and 1896, arrived independently at the same conclusion. Discussing the assay of rocks, he says,¹⁵ "The statement of Dr. Don that country rocks can be assayed by panning down a quantity and assaying the residue has been tested, as well as the statement that pyrites must be present in order to find gold; and my experiments show that both statements are incorrect—or, at least, not in accord with my experience."

At Te Aroha, near the northern boundary of the central volcanic region, there are (in the andesites) hot springs; 25 miles distance, soda-water springs; and at the Thames, ten miles further north, gas springs which discharge enormous volumes of carbon-dioxide. In the mines at the north end of the Thames Goldfield, the CO₂ issues with great force from cracks and fissures in the rocks. The mine-shafts are situated near the foreshore, and descend to depths varying from 500 to 900 ft. below sea-level. In close muggy weather in summer, with a low barometer, the gas rises in the mines, and, flooding the workings, drives the miners before it. Sometimes the gas rises up to the top of the shafts and overflows at the surface. Notwithstanding the special precautions employed to effect ventilation and to warn the men of danger, several fatal accidents have taken place in the past thirty years.

In the Big Pump shaft, the CO₂ escapes with such force as to cause violent boiling all over the surface of the water in the well. The depth of the shaft is 640 ft., but the workings are flooded up to the 500 ft. level, in consequence of which the gas escapes against a head of 150 ft., equal to a hydraulic pressure of 65 lb. per square inch. The commotion at the surface of the water at the 500-ft. level is caused by the escape of the gas which is not dissolved by the water. The pump has been raising water from this shaft for over a quarter of a century at the rate of 750 gal. per min. The water is so highly charged with gas as often to cause trouble in working the pumps.

¹³J. R. Don, 'The Genesis of Certain Auriferous Lodes,' Trans. A. I. M. E., Vol. XXVII, p. 561.

At Waihi, Kuaotunu, and Great Barrier island there are huge veins of quartz, mostly chalcedonic, many of which are still capped with wide mushroom-shaped quartz 'blows.'

Posepny¹⁶ mentions the remarkable occurrence of tree-stems changed to galena in the Vesuvian mine, Freihung, in Bavaria. In these the fibre and annular rings can be easily recognized, being extremely plain on polished surfaces. In the tuff-beds associated with the gold-bearing andesites, masses of wood, partly or wholly silicified and spangled with nests and veins of iron pyrite, are of common occurrence throughout the Hauraki region.

The Martha Lode and its numerous ramifying branches, the Silvertown, Union, and Amaranth lodes, at Waihi, are all contained in an area of about a square mile. The huge lodes, wide zones of silicified andesite, and extensive propylitization of the andesite, prove that Waihi was an area of intense hydro-thermal activity some time prior to the eruption of the later rhyolite flows which now form the plains and wrap around the isolated outcrops of andesite containing the Martha and Silvertown veins. The propylitization has already been shown by the Waihi workings to extend to a depth of nearly 800 ft. below present water-level—that is, some 500 ft. below sea-level. Obviously, the alteration of the andesite was due to the action of ascending and laterally moving thermal waters.

At Thames and Coromandel some of the most productive veins do not reach the surface of the enclosing rock, and the mine-workings at Waihi have disclosed a similar feature in connection with a few valuable veins in the Waihi company's property.¹⁷

In 1888 Captain F. W. Hutton, as a result of a petrographical examination of the Thames mining district, concluded that the veins were of hydro-thermal action.¹⁸

T. A. Rickard, a well-known American geologist who examined the same goldfield in 1891, when discussing Professor Posepny's paper on 'The Genesis of Ore-deposits,' describes the characteristic features of the district with the view of adducing additional evidence of the association of thermal springs and later eruptive rocks.¹⁹ He states that his examination of the ore-occurrences and vein-structure, though incomplete, led him to conclude that the deposition of the gold and its associated minerals had followed certain lines of altered country rock which had been exposed to the effects of dying but lingering solfataric agencies.

SKY-SCRAPERS.—An eminent New York engineer and practical builder who has to his credit many of the finest skyscrapers of the metropolis, states that a 100-story building, built of reinforced concrete, and towering more than 1,000 ft. from the ground, may yet be seen by people who are living and even reached middle age. The 50-story buildings which are being seriously considered as a future possibility, will constitute but a stepping stone to the 75-story buildings and then to the 100-story buildings. The principal drawback which now presents itself is said to be the impossibility of providing elevator accommodations for even a 50-story building, for the reason that the weight of the cable to support a car in the numerous 30-story buildings now in commission, is enormous, and some other method of utilizing the upper floors will have to be invented and introduced before the skyscraper can be built any higher. The limits of the elevator, as understood at this time, have already been reached.

Mine and Mill Reports.

Written for the MINING AND SCIENTIFIC PRESS
By J. T. THOMPSON.

The form of many mine reports evidently assumes the work of an extensive office force and suggests that they were prepared by or for the expert accountant; the result is that they are too complicated, not elastic enough to be used or applied in a practical manner by practical men, especially in the early stages of development, when systematic accounts are seldom attempted, and in consequence many valuable data are lost.

To be effective, a form of report easily understood by the average foreman is a necessity; it should be of such construction as to be readily compared, and also capable of expansion as the work progresses, without the necessity of change. The final summing up must be done in the office, to an extent depending on the manager or book-keeper, the former with simple blank forms and a

SURFACE AND HOIST REPORT.

very simple outfit of books can have his mine accounts in excellent shape with a minimum expenditure of labor and time; from these records the accountant can elaborate to his heart's content.

The models of reports herewith submitted have stood the usage of over 12 years in nearly every form of metal mining, from Peru to Alaska, and it is surprising how well they fit every demand. It is not claimed that they are perfect and any suggestion of improvement will be gladly welcomed, but theoretical additions, it must be borne in mind, are not always improvements. Simplicity is what is desired, otherwise the value of such reports is questionable; and the same applies to them if they are filled out in perfunctory, mechanical way, or by guess. Aside from many other advantages, their value in systematizing the foreman's work is much more than the cost.

With the exception of the battery ticket, the reports are printed on paper 8½ in. wide and 14 in. long. The battery ticket is 5½ in. wide by 7 in. long. Certain omissions are intentional and in some cases it will be necessary to fill in the report at the office to make it complete. To prevent waste of the blanks, and prevent duplication as far as possible, it may be advisable to number them consecutively, requiring defaced blanks to be returned.

MINE REPORT.

This report to include all work in mine, other than track, cars, shaft repairs, pumps.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

HYDRAULIC MINING APPARATUS.—No. 832,066; John Larsen, Burntranch, California.

The combination with the nozzle of a hydraulic mining apparatus, of a tubular deflector having a swinging connection with the nozzle and provided with external projections, and a controlling handle having a loop embracing the deflector back of the projections, the loop being provided with internal seats capable of alinement with the projections to permit application and removal of the loop.

BRIQUETING MACHINE.—No. 832,553; Howard E. Marsh, Los Angeles, California.

The combination with a main shaft, of a revoluble drum thereon having peripheral molds opening at the periphery of said drum, plungers in said molds, a compressor-arm pivoted externally of said drum in proximity thereto, means eccentrically connected with said shaft for operating said compressor-arm, an eccentric on said shaft, a strap operatively connected therewith, said strap provided with a hollow rod, a compressor-plate telescopically connected with said hollow rod, a spring interposed thereabout, and ejector means.

MANUFACTURE OF FLAKE MICA FROM MICA PLATES, CRYSTALS, OR NODULES.—No. 832,494; Henry C. Mitchell, London, England.

Apparatus for the manufacture of flake mica from mica plates, comprising one or more pairs of bending-rolls, means for conducting the mica plates between said rolls, a flaking-chamber provided with an inlet-chute inclined to the length of said chamber, means for conveying loosened and partly-

opened mica plates from said rolls and introducing them into said inclined chute and flaking-chamber, means for forcing a blast of air into said flaking chamber, and a splitting and separating chamber in communication with said flaking-chamber.

FURNACE-CHARGING MECHANISM.—No. 832,536; David Baker, Wayne, Pennsylvania.

In a furnace-charging mechanism the combination with a receiving-chamber communicating with the interior of the furnace, of a distributing-bell adapted to close the lower end of said chamber and constructed to accumulate the stock delivered to the chamber to one side of the same when the bell is in closed position, means for opening the distributing-bell to discharge the contents of the chamber, and means for shifting the position of the bell to vary the point of discharge.

PROCESS OF SMELTING COPPER MATTE.—No. 832,738; William Kemp, Tucson, Arizona.

The method herein described of producing metallic copper directly from copper matte, which consists in subjecting the matte, while in hard condition, and in the presence of a flux, to the melting action of the flame of a burning mixture of oil-vapor, steam, and air.

AUTOMATICALLY-OPERATED SWITCH.—No. 832,659; Charles F. Eldridge, Herrin, Illinois.

In a device of the character described, a main line, a siding, a switch, means for automatically operating said switch, including a single tripping device positioned beyond the heel of said switch and adapted to be engaged by a wheel of a car after passing over said switch to throw the same to connect the main line and siding, and means for locking said switch in its open and closed position.

The Brothers Balanced Cableway.

What is claimed to be an important improvement in the construction of cableways is that known, from its patentee, as the Brothers Balanced Cableway, or Cable Crane.

The distinguishing feature of this engineering device is the employment of a counterweighted cable connecting shear legs free to oscillate in a vertical arc and the use of a self-propelled trolley or carrier, thus dispensing with all overhead ropes except the cable itself, which can be both shorter and lighter for a given working span and load, than that employed in the older form of cableway.

This arrangement is shown diagrammatically in Fig. 1, which illustrates the Brothers cableway successfully used in the building of the recently completed bridge across the Zambesi river in central Africa.

The Zambesi installation was used not only for transporting bridge material from the bank to its desired place in the structure, but for carrying entirely across the river all the material used in the construction of some 100 miles of track beyond the river, before the use of the bridge itself was possible. It is stated that on some days as much as 1,000 tons of material was thus transported. The working capacity of the cableway was 10 tons. The span was 870 ft., and the counterweight of the cable 144,400 lb. The counterweight

The hoisting of the load and the travel of the carrier on the cable is by an electric motor geared to the hoisting drum and to the carrier wheels, this motor being supplied with current from a generator placed at any convenient point, and transmitted from one of the towers to the carrier by a flexible copper cable. It is claimed for this system of cableway construction that a minimum of labor expense is incurred in operation, as the operator on the carrier is so situated that he can direct the work without the assistance of signalmen. On account of the lightness of the towers and the small amount of overhead rope these plants can be moved from place to place with the greatest facility.

Until recently these cableways have been installed by W. F. Brothers, the patentee. The business has now been taken over by a company for which Mr. Brothers is consulting engineer, namely, The Balanced Cable Crane Co., of 135 William St., New York City.

Notice.

The Fred. M. Prescott Steam Pump Company is the owner of several patents upon triple expansion and multiple expansion engines, invented by Fred. M. Prescott, Milwaukee, Wis. These comprise United States patents 751,997, dated Feb. 9, 1904; 751,996, dated Feb. 9, 1904; 751,995, dated Feb. 9, 1904; 719,367, dated Jan. 27, 1903; 719,136, dated Jan. 27, 1903.

This company also owns several applications pending in the patent office, upon which patents are shortly expected to issue, covering other features in triple expansion and multiple expansion engines. These patents are considered to cover all available forms of construction including arrangements of piston rods and steam cylinders, which provide the one great desideratum in pumps and engines of this

class, that is, accessibility of its parts and the ability to examine or remove any of the pistons or rods without tearing down or disturbing the steam cylinders or any of the heavier parts of the engine. Without these distinctive features the so-called triple expansion pump loses entirely its commercial utility.

There is no use, therefore, in our dilating further upon the advantages of our patented constructions, as they are fully appreciated by every engineer and user of this class of machinery. They are the product of much study and many years of experience in the development of pumping engines of these types and adapting them to various local conditions, on the part of Mr. Prescott, and are features of the utmost value to this company. It is, therefore, necessary for us to protect our rights and the exclusive ownership and control of these patents to the utmost.

We are sorry to note that certain infringements have been offered to the trade, and in all courtesy we desire to notify any would-be purchasers of the existence of our rights and that we shall be compelled to uphold and defend them wherever infringed.

FRED. M. PRESCOTT STEAM PUMP COMPANY.
Milwaukee, Nov. 6, 1906.

The Cia. Metalurgica de Michoacan, at Ocampo, Mexico, is installing a complete electrical plant, comprising apparatus from the works of the WESTINGHOUSE ELECTRIC & MFG. CO. What is called a three-wire arrangement is applied, which by an ingenious invention owned by the Westinghouse company, renders it possible to obtain 250 volts and 125 volts from the generator.

Fig. 1. The Brothers Balanced Cableway Across the Gorge of the Zambesi River.

had a vertical movement of 51 in. as the load crossed from one side of the river to the other, which movement of weight computed as horse-power, was equivalent to 17 h.p. per min., delivered at the load. That this movement of the counterweight was most effective when it was most needed, that is, just as the load was approaching the tower, was shown by noting its movement as compared to the travel of the load on the cable. With the load in the middle of the span, 435 ft. from the tower, the deflection of the cable was 43 ft. 6 in., raising the counterweight 4 ft. 3 in. The counterweight and shear leg would be lowered about 12 in. during the first 200 ft. of travel of the load, 12 in. during the next 135 ft., 12 in. during the next 50 ft., and 15 in. for the last 50 ft. of the load's movement. It is stated by the builders of the cableway that the saving in money due to this feature of balancing, and saving in maintenance of auxiliary machinery which would otherwise have been required, at the cost of power and repair work which prevailed at the Zambesi plant, was upward of \$4,000 per year.

Owing to the design of the struts supporting the cable in the Brothers system, it is possible to place the feet of these close to the edge of the ground to be worked over, and from the fact that the cable is nearly horizontal as the load approaches the towers, to make them of less height than is necessary with other cableways, so that a shorter length of cable is required, and this of lighter section for the same working capacity, thus reducing first cost, freights, and cost of erection where it is to be used. It is entirely feasible to have these cableways deliver material 'behind' the towers, this having been done in most of the installations so far.

Editorial.

THE UNITED STATES Geological Survey is publishing much invaluable material. We have just received J. E. Spurr's report on the Silver Peak district of Nevada, and N. H. Darton's work on the Bighorn Mountains of Wyoming. Both 'professional papers,' as these handsome treatises are termed, are splendidly representative of the science of the geologist and the art of the printer. No other geological survey in the world turns out such material as this in such a manner.

THE ARTICLE by Mr. Waldemar Lindgren will be appreciated by thoughtful readers. His terse summary of recent mining history is interesting and his comment on current conditions will win attention, for no one is better qualified to discuss these subjects. When will the era of new discoveries cease and when shall we have to fall back on the re-treatment of dumps and the beneficiation of low-grade ores only profitable when submitted to newer methods? We trust that uninteresting era will be after our time and we believe that there is still enough untried country to furnish discoveries for many a year. On another matter, that of the unintelligent marketing of ores, Mr. Lindgren gives good advice. People who sell their product without knowing just what it carries are likely to be misled, for it is not the business of smelting companies or sampling works to furnish gratuitous analyses. Gentlemen, utilize the services of the assayer and the chemist, to the end that you may work less in the dark and more in the ample light of ascertained fact.

THERE IS much talk in the daily press of the shipment of a million-dollar carload of ore from the Mohawk mine at Goldfield, Nevada. The fact is that the Hayes-Monette lease has yielded a carload that has been sampled already, the 35 tons having a gross value of \$490,000. This is not a million, but it is a remarkable shipment; and being a fact, it is more interesting than the current stories. The time was when a carload meant 20 tons on a broad-gauge railroad and 10 tons on a narrow gauge, but nowadays the capacity of rolling stock has been increased to a maximum of forty or fifty tons of ore. With such stuff as Goldfield produces, a 50-ton car would have to average \$20,000, or, say 1,000 ounces of gold per ton, to make a million dollars. Such a shipment is by no means improbable, if lessees or mine owners are willing to accumulate their best product in order to play to the gallery. Meanwhile, these are great days at Goldfield. An option on the Combination mine for the sum of \$4,000,000 has been given to Messrs. Nixon and Wingfield, who represent the Goldfield Consolidated, a company recently formed by the merging of the territory covered by the Mohawk, Jumbo, Red Top, and Laguna mines. The Combination ground covers 205 acres and has produced nearly \$2,000,000. If the option is ex-

exercised, the Goldfield Consolidated will become one of the great gold mines of America.

THE FARMERS in the Salt Lake valley have nearly killed the goose that gave them golden eggs. By their blackmailing suits against the smelters, they threaten to close the Murray plant of the American Smelting & Refining Company, and the smelting works of the United States Smelting, Refining & Mining Company, as well as those of the Utah Copper and Bingham Consolidated mining companies. The latest ruling is that the ore to be smelted must not contain more than 10 per cent sulphur, but it is not clear whether 4% stuff may be averaged with 16% sulphur ore. If such a mixture is not permissible, may material containing varying percentages of sulphur be mixed before delivery? It might be done at the mine or at the sampling-works. The incident illustrates the difficulty arising from unscientific applications of technical distinctions. At the present time the big lead smelter at Murray receives the galena concentrate from Park City; this material carries 12 to 15 per cent sulphur, and if the treatment of it is prohibited, the Murray plant must close down. The ranchmen of the Salt Lake valley apparently are destined to give an accentuated meaning to the term 'farmer' when used as a synonym for slow intelligence.

ON ANOTHER PAGE we publish abstracts from two reports of important mining companies. We advise the younger men—and others who are willing to learn—to read such reports, because they give valuable hints regarding the difficulties to be encountered in mining. The story of a prospectus and that of actual operations present a suggestive contrast; it is the difference between a forecast and a fact. Engineers will do well to get alongside the latter. Both at the Dolores and the Oriental mines there has been, and there is now, engineering talent of a high order, therefore the straightforward record of experience ought to be of service. At the Mexican mine the questions of transport, labor, and supplies have proved difficult, as they always are at new mines in out-of-the-way localities. Young engineers—and some old ones—are apt to minimize the importance of these factors in their relation to the earning of dividends, therefore Mr. John B. Farish's account ought to be helpful. Wide apart as the two mines are, it is interesting to note that tube-mill experiments are being made at both of them, and in Korea the testing of dredging ground is being carried out with a care that bespeaks sane management. In mining, as in other industrial enterprises, it is better to be sure than sorry.

WE PUBLISH some interesting comment by Mr. Philip Argall in regard to the report of the South African committee on the Standardization of Screens. The report will be useful, although in this case, as in other investigations of the same character, it would be more scholarly to acknowledge the efforts of those who have worked toward the same end. We have criticized the misuse of the term 'mesh' in these columns and in another place during the last four years, so that the findings of the committee are most welcome. It is to be hoped that

technical writers, including the editors of the transactions to which they contribute, in South Africa, will take note of this matter. When men write, for example, of 200 mesh and mean 200 holes per square inch, confusion is sure to arise. 'Mesh' indicates the number of holes per linear inch without reference to the size of the aperture or, in other words, the width of the wires or metal separating each hole; therefore it is a step forward in precision of speech when 'merh' is tabooed and 'aperture' is adopted. We hope that such phrases as " $\frac{1}{4}$ inch mesh," meaning $\frac{1}{4}$ inch holes, will now disappear. Accuracy of statement always aids clearness of thinking.

A Regrettable Incident.

We have received a reprint of the correspondence between Mr. John C. Branner, professor of geology in Stanford University, and the Director of the U. S. Geological Survey, which appeared in *Science* of October 26. On the face of it, a grave injustice appears to have been done to a distinguished scientific man and a veteran geologist. Professor Branner was formerly State Geologist of Arkansas, and made the first authoritative surveys of the coalfields in that State. Owing to lack of funds, the final report was never published. There is a demand now for the completion of the work, with additional surveys to bring it up to date. The Director of the Survey wrote recently asking Professor Branner to co-operate. This he was willing to do, provided he was given charge of the investigation. In reply, the Professor was told that there were a lot of men on the Survey who were available for the duty and that the original work done by him would be of no practical value to them. Thereupon Professor Branner resigned from the Survey and wrote saying that the action of the Director was "an outrage and an unwarranted personal affront to which no self-respecting geologist can tamely submit." In this we agree with him; it was in the nature of the maximum injury it was possible to inflict upon a high-minded scientific man. Then followed a final exchange of letters, the Director stating that the original Arkansas survey was marred by many serious errors, making a re-survey necessary, while the Professor retorted by asserting that the maps of the U. S. Geological Survey in Arkansas were so poor as to be practically worthless and that if the topography needed revision it could be revised as well for him as for some one else. In concluding, Professor Branner makes a vigorous attack on the tendencies of the officials at the head of the U. S. Geological Survey, claiming that this national bureau has grown into a scientific trust and that geologists are not treated with common courtesy unless they have political backing.

The episode is most regrettable. It will be taken as evidence of the desire of the Survey at Washington to encroach upon the rights of individual geologists and of the State Surveys. Certainly, it looks as if the latter were to be slowly snuffed out. The political pull behind the bureau at Washington is too strong. In the Irrigation Congress, in the Mining Congress, and in other organizations of the kind, the officers of the Survey have taken prominent part, thereby strengthening their position before those who vote for appropriations in Congress. It

is a pity that our legislators do not see the great service done to the country by the scientific investigation of its resources, without requiring the investigators to spend so much time in the lobby, and it is a greater pity that to emphasize the necessity for its existence, the Survey must invade the domain of others, just as well qualified to do geological work. This last incident is quite in line with the contention that we have made on previous occasions, that the Geological Survey is becoming an unwieldy bureau, in which the scientific spirit is being killed by too much politics and by the spreading out of its activities so that they include forestry, irrigation, reclamation, and other such matters as do not belong to a geological department.

Health Underground.

In our last issue we gave a summary of the investigation recently made into the unhealthy conditions among which the miners work in the deep mines of Bendigo. It is asserted that Bendigo miners die at the average age of 41 years. Certainly, it was time to do something. The Mine Managers' Association in that celebrated district has taken the matter to heart and there is good reason to expect that greater care will be taken to connect the deep workings, so as to stimulate natural ventilation, and also to encourage the more general use of atomizers and water sprays in raises and in the dead ends of drifts or cross-cuts. In South Africa, also, the waste of life in mines is attracting attention. It is claimed that the accident rate is abnormally high, and that it is due to preventable causes. The inspectors fail in their duty. In 1905 the average fatality rate was 7.35 per thousand, the rate being highest among the white miners. Last year it was 9.6 per thousand, as compared to 2.49 in the English metal mines. The Government Mining Engineer has complained of his inability to enforce the regulations. This is a blot on the economies of mining on the Rand, for, apart from even the commonest feeling of humanity, it is obvious that physical danger and good workmanship cannot go together. Mine managers everywhere are lacking in sense if they do not appreciate that the cost of mining is in direct ratio to the efficiency of the apparatus they employ, and of all the machinery in a mine none is affected by unfavorable conditions so greatly as is the muscular machine known as a man. This is generally appreciated nowadays; there was a time when workmen were treated like cattle, and the employment of convict labor in Europe or of colored races in other parts of the world had a bad effect in rendering superintendents careless of the physical protection of those who pursue an occupation that can be made—though it is not necessarily—hazardous by disregard of ordinary precautions. On the Rand they need labor so much that it seems reckless to squander it—in accidents. At Bendigo they endure unhealthy conditions simply because they have become used to them, until someone from the outside exposes the barbarity of it. Two such famous mining centres ought to be an example, instead of a warning, in the safe-guarding of health and life underground.

By the Way.

On the occasion of the opening of the new Engineering Building of the University of Pennsylvania, Mr. Charles W. Baker, editor of *Engineering News*, said:

It may be a new idea to many of you that the Technical Press is a school. It never has been counted in by the statisticians of the Bureau of Education. No State nor city pays taxes for its support. Not one tainted cent of anybody's money has ever been invested for its endowment. Yet I will vigorously defend the thesis that the Technical Press is a school; and a school whose influence for progress can hardly be overestimated.

The building today dedicated will shelter about 600 students; but in the world-wide class-rooms of my own institution you may find thrice as many thousands. The students of the technical school are boys, perhaps 18 to 23 years old; but the students of the Technical Press include not only these youths, but their instructors as well, and not only the instructors, but the men in active professional work, ranging all the way from the green graduate, trying to hold down his first job, to the Nestors of the profession, full of years and honors, and let us hope of dollars also.

Pardon me if I make one more comparison. The boys who receive their training in the fine building dedicated today are not, at their graduation, engineers. They have only laid a good, strong, permanent foundation. The force headed by Professor Marburg and Professor Spangler have sunk the caissons deep in those hollow skulls and filled them with concrete—facts. It is a fine foundation, clear up to the capstone on top of the pier—but the superstructure is still to be built. The boy goes out after graduation and goes to work to become an engineer, and his instructor and mentor and aid in this post-graduate course is the technical journal.

I want to emphasize the fact that it is the superstructure and not the foundation which it is the business of the Technical Press to build. Any intelligently conducted technical journal excludes from its columns elementary matter, contained in standard text-books, and also everything which is already matter of common knowledge in the profession. It seeks for the benefit of its readers the sort of information which is not yet found in the text-books nor taught in the class-rooms. Wherever a man is doing work in a new and a better way with new and better tools or machines—wherever progress is being achieved—it is the province of the Technical Press to make that progress public for the general benefit.

And now let me point out to you one radical difference between the technical school and the Technical Press School. The professors in the technical school are there to instruct their pupils; but the editors of the Technical Press are never wise enough to instruct all of their readers all of the time. The wisest attempt it least. The real teachers in the Technical Press School are not the editors, but the contributors. The technical journal is a co-operative exchange. Its business is to tell the story, week by week or month by month, of current progress. Its pages are wide open to the man with a record of progress—real progress and not mere blowing of horns—if that record will be of practical service to the readers. The editor's function is like that of a baseball umpire—to say what is a hit and what is a foul and to endure with patience the objurgations of those who object to his decisions.

AN interesting contrast between the geology of the present day and that of half a century ago, is presented by the complete emancipation of the modern geologist from the controlling and perverting influence of theology, all-powerful at the earlier date.

Special Correspondence.

Johannesburg, Transvaal.

A Bad Accident.—Gold Reserves.—Publication of This Account.—Scarcity of Labor and Cash.—Several Mines Shut Down.—J. H. Curle is Justified.—Decreased Immigration.—Fewer Chinese Outrages.

We were horrified two days ago by a skip accident on the Simmer East mine. While the man-cage containing 23 Chinamen was descending the shaft, the rope broke about 700 ft. from the surface, and the unfortunate victims fell a vertical distance of 1,200 ft. They were crushed to a pulp, and were buried in one grave, as it was impossible to identify them. An investigation no doubt will be made by the Government. The first report is to the effect that the accident is not due to a defective rope, but that a bolt in the drum on the engine worked loose, caught the rope, and caused it to snap. This is the

Map of the African Goldfields.

second serious rope accident on the Rand since the war, the other one having occurred on the Robinson Deep, when 40 or 50 Kaffirs were dashed to pieces.

During the past week two important yearly meetings were held, those of the Nourse Mines Ltd. and the Langlaagte Deep. Reference was made to the practice of keeping gold reserves on the Rand. Every mine that can do so, builds up a reserve, varying from a few hundred to several thousand ounces. Even on the Rand, where the ore is fairly constant in value, compared with other places, it is found difficult to keep up a uniform output without a reserve. It is fair to state that this reserve has never yet been used for market rigging purposes, as in other places. By careful calculation the grade of a mine is determined, and if in any month the output is too high, a few hundred ounces are put to one side. In the past the shareholders have not been told what amount of gold was held in reserve. This policy is to be changed in the future, as was intimated at the two meetings held last week. Along with the monthly output will be published a statement of the reserve gold account, so that shareholders may know exactly how they stand. It is probable that all the mines

of the Rand will follow this example of publishing the reserve account.

Many developing mines are closing down, on account of the uncertainty of the labor outlook. In the Eastern Rand the Cloverfield mines have ceased work; also the Driefontein Deep, while several other developing mines are on the verge of ceasing work. Many of the developing mines will be forced to close down on account of a shortness of cash. The market is so bad at the present time that it is nearly impossible to dispose of reserve shares at anything like a decent figure. By glancing down the list of shares quoted, one soon realizes that deep-level propositions are distinctly out of favor with the investing public. Shares that stood at 70 to 80s. a year or so ago can now be bought for 19 to 20s. None of the deep-deeps stand much above par. During the 'deep level' mania, people were paying fancy prices for these shares. The very disappointing results obtained on some of the new deep levels account for the depreciation of these shares. For a long time people spoke of Mr. J. H. Curle as a rank pessimist, when he cast doubt on the value of mines deeper than 3,000 ft., but his words are coming true to a great extent. The only hope is for reduction in working costs.

As could be expected, there is a big slump in the building trade of Johannesburg. Most artisans who could afford it have left the Rand. The incoming boats are bringing very few passengers to South Africa. The news of the severe depression seems to have traveled far and near, so that workers are afraid to come to South Africa. For farmers there is little chance in this country without capital, so farm hands leave Africa severely alone, and migrate to America or Australia. Last January the number of buildings erected was 627, valued at £173,298, while in September there were 350 buildings built, valued at £76,676.

There has been no Chinese outrages during the past fortnight. Most of the desperate characters have been sent out of the country, so that there should be much less crime than formerly.

Joplin, Missouri.

Record Production—Year's Output Worth Fifteen Millions—Several Strikes of Ore—Successful Drilling.

For the first time in the history of mining in this district, the value of a single week's shipment exceeded \$400,000, and it created less excitement locally than when a single week's value first passed the \$100,000 mark. That event was in the latter part of the year 1889, when zinc ore reached the then unprecedented value of \$32.50 per ton, and lead ore was \$57 per ton. Last week zinc ore was selling for \$49 per ton and lead ore at \$85.50 per ton. Not only was the value greater last week, but the shipment of zinc ore was 320 tons more than the largest week heretofore, which was the second week in last May. The lead shipment was 248 tons less than the big week in May. The figures for last week were: Zinc ore, 14,975,890 lb., valued at \$339,125; lead ore, 1,592,180 lb., valued at \$63,574; combined value, \$402,699. Compared with the same week last year this was an increase of 5,354,220 lb. zinc, and 335,170 lb. lead ore and an increase in value of \$133,024. Compared with the previous week this year, it was an increase of 5,136,300 lb. zinc, and a decrease of 44,400 lb. lead ore and an increase in value of \$122,059. The shipment for the 46 weeks of this year is 495,105,900 lb. zinc and 69,386,100 lb. lead ore, with a combined value of \$13,387,784, which is an increase over the same period of last year of 46,105,460 lb. zinc and 13,462,200 lb. lead ore, and an increase in value of \$1,631,459. If the remain-

ing six weeks of this year keep up, the average ore output will exceed \$15,000,000. The first touch of winter came last Sunday night with a vengeance and has continued thus far into the week; so that this week's shipment is likely to be below the average.

The Ideal Mining Co., operating on the Rex Mining & Smelting Co.'s land east of Joplin, three weeks ago, sold about 700 tons of zinc ore to the Mineral Point Zinc Co. and last week finished loading it into a train of 21 cars. The ore was an accumulation formed since they started the mill on August 9, and has all been produced from the 50-ft. level.—A big strike of lead was made last week on the Smith & Stickney lease, at what is called Four Corners, north of Joplin. The lead was found in running a drift at the 30-ft. level and 6,000 lb. was hoisted in a few hours' work. This lease has been producing zinc and lead for some time, but the lead has never been found in the quantity that this new strike shows it.—The Whitsett Mining Co., operating on the Trinity Zinc Lead & Smelting Co.'s lease at Porto Rico, made its initial turn-in last week, amounting to 61,990 lb. zinc ore. The Trinity Co. has a large tract of land lying south of the Ground & Irwin lease at Porto Rico, and in a short while there will be lively competition between the two companies for first place in the Duenweg district. The Chapel mine is also on the Trinity lease, with two or three more soon to open up.—The Alliance Land & Mining Co., operating on the Louie Stevison land north of Duenweg, made its first turn-in last week, amounting to 17,730 lb. lead ore. They have a new modern mill and will soon be classed among the regular producers.—Chapman & Lennon, owners of a lease adjoining the Underwriters' Land Co., north of Webb City, now have their shaft down to the ore, which is said to be as rich as any in that section. Their new mill, which they have been building while development work was going on, is rapidly nearing completion, and by the time the ground is thoroughly opened up, it will be ready to handle the dirt.—The Granby Mining & Smelting Co. discovered a good body of ore in the second hole they are now drilling on their land near Chitwood. This hole was put down about 180 ft. west of the first one, in which a limestone bar was encountered and no ore found. Their drilling is for the purpose of locating the lime bars, as well as the bodies of ore.

Calumet, Michigan.

Hancock Consolidated.—The Arcadian and Its Prospects.—Testing the Nonesuch.—Experiments in the Baltic and Champion Mills.—The Michigan Mill.—Activity in Keweenaw County.—Satisfactory Development in the Superior.—Mass Copper in the Michigan.

Mining operations in the Hancock Consolidated mine were started this week. The old shaft on the original Hancock mine was unwatered a few days ago; the workings are being cleaned out and other preparations made for pushing development along broad lines. It will be impossible to operate on a large scale until the shaft and workings are in fit condition. The skip-road in the shaft is being repaired and new rails laid in places. The timbering was made secure as unwatering advanced. It is uncertain when the repairs will be completed, but it is expected that everything will be in shape by the end of next week.

In barring down the loose ground in the shaft and drifts in order to render the workings safe, some copper ore has been exposed. All the ground has been stoped out in the old Hancock as far as the drifts extend, but it is expected that drift stopes will be started at the most favorable points so as to permit of immediate production.

It is the policy of the management to place the mine on an earning basis just as soon as possible. It is expected that next month the big vertical shaft that is to open the Quincy, Hancock, and other lodes in depth, will be started.

As the Hancock will be producing in a short time, it is interesting to note what its production was under the former management. The mine was first opened in 1861 and worked intermittently until 1885, when copper slumped to 10 cents per pound, forcing the suspension of operations. Between 1861 and 1885 the mine produced more than 5,750,000 lb. refined copper, and during the last eighteen months that it was active the ore averaged 20 lb. copper per ton. With the modern methods now in vogue, it is expected that a greater copper recovery will be effected so that the rock should yield at least two or three pounds of copper more to the ton. The old Hancock mine comprised only 140 acres, in which is sunk the shaft where operations were resumed recently, but the Hancock Consolidated Mining Co., the present concern, owns 860 acres. The best portion of the Quincy mine adjoins the Hancock boundary. In connection with the sale of a portion of the Arcadian lands to the Quincy company, it may be said that the organizers of the Hancock Consolidated, which secured much more valuable lands, secured them at far better terms. This was possible because the St. Mary's Mineral Land Co., which disposed of 600 acres to the Hancock company, took stock in payment and will participate in the benefits arising from their development.

There have been no developments of importance lately on the Arcadian property and no rich lode has been encountered as reported in some quarters. An examination of the burrow pile shows that both a conglomerate and an amygdaloid have been penetrated in the cross-cut on the 200-ft. level of the new shaft, but no positive value can be attached to either, nor do they furnish any positive identification of the territory. The amygdaloid is not a particularly strong formation and contains very little copper. Talk of "hidden values" in the Arcadian is unfounded. The amygdaloid that was cut in the cross-cut cannot be positively identified and few experts or engineers care to commit themselves in regard to it. By some it is believed to be a northern extension of the Baltic lode, while others say that the distance from the Great Eastern sandstone is such as to make it difficult to correlate with the Baltic. Its identity, however, is of secondary importance. The main question is its copper content, and from the limited amount of work done it would seem that the lode is far from being rich.

It is expected that the Calumet & Hecla will finish the work of erecting a stamp-mill on the Nonesuch property, in the Porcupine Mountain district of Ontonagon county, within a short time. The plant is being equipped with heads of limited capacity and the mill will be used to test the ore from the old Nonesuch mine, on which the Calumet & Hecla company holds a three years' option. The workings of the mine were pumped out some time ago and some of the openings are being extended. Diamond-drill work also is being continued and the property will be thoroughly explored.

The machinery forming part of the additions to the Baltic and Champion mills will be put in place within the next three weeks. The capacity of each addition is to be equivalent to two stamps, that is, 1,400 tons per 24 hours, making 2,800 tons altogether. The addition to the Champion mill is now occupied by an experimental graded crushing system of treating the copper ore; this has a capacity of half a stamp. Further experiments are being made.

In the Trimountain stamp-mill no changes are to be

made. The four heads which are in that plant were recently equipped with the steeple compound cylinders, increasing their capacity considerably, and no further increase in the capacity of the plant is planned for some time.

At the Michigan Co.'s millsite on Keweenaw bay the shaft has been completed; from the bottom of it a drift will be extended under Lake Superior to serve as an intake for the water supply. It was sunk to a depth of 80 ft. The foundation for the stamp-mill is completed, but it is not planned to erect the superstructure until next spring. The mill will contain only one stamp at the start; it will be of the steeple-compound type, but the building will have a capacity for two heads, so that a second one can be added.

Present indications point to important developments in Keweenaw county. A large part of the mineral area of the county is now owned by the Calumet & Hecla, Keweenaw Copper, and Tamarack companies, but a fourth

has arrived from New York and will examine the Michigan and other Lake Superior copper mines with which he is identified.

Butte, Montana.

Wages Increased.—Dealers Raise Prices.—Difficulty Adjusted.—Good News From the Snowstorm.—Operations in North Butte.—Development of the Parrot.—Silver Strike in the Eagle.—Lack of Cars.—Heinze Buys the Stewart.

The scare over rumors of a contemplated strike among the Butte miners to enforce a demand for \$4 per day of eight hours for all underground men, has been dissipated by the miners themselves. They will not enforce the demand and have decided to accept the raise of 25c. voluntarily made by the mining companies, which has placed the wages of underground miners at \$3.75. As soon as the mining companies announced that a million dollars per annum in additional wages were to be distributed among the 10,000 miners, provision dealers, fuel dealers, liverymen, and funeral directors quickly conceived the idea of getting the biggest portion of the increase. Undertakers increased their rates, the price of coal was advanced 50c. per ton, the liverymen raised the prices of their carriages \$1 per funeral. Other living and burial expenses were increased in proportion. Then the miners protested. They said the cost of living had in a few weeks advanced more than the 25c. increase would offset, and a committee was appointed by the Union to call on the managers and request an increase to \$4 per day. The miners thought the companies might be able to pay that while copper is selling at 22c. per pound, or near that price, if they could afford to pay \$3.50 per day when copper was selling at 9 and 10 cents, and pay dividends at the same time. The mine managers told the committee, however, that no further increase in pay would be granted. Then there were scares about a possible strike and a suspension of prosperity in Butte. At the next meeting of the Miners' Union the committee made its report; the report was received and the committee discharged. Then a motion was made and adopted that the raise of 25c. be accepted and the managers thanked for the voluntary concession. That ended the incident, and everybody in Butte has been praising the miners for their level-headedness and conservatism. The fact remains, however, that the miners are the poorest paid of any laborers in Butte; that they are in the hardest occupation and the most dangerous to health and life. Hod-carriers get \$6 per day, and the commonest laborer above ground gets \$3. "The rumors about a strike," said President Duffy, of the Miners' Union, "came from irresponsible sources. No strike has been in contemplation. Much dissatisfaction has been expressed over the fact that there has been a raise in the price of almost everything which we have to buy for our households. A committee was appointed to represent to the mine operators that the price of living had advanced to such an extent that it did not seem to us that the increase offered by the companies would be sufficient to cover the increased expenses of living. We want the people to know that the Miners' Union is just as conservative a body as ever and that we may be relied on to conduct matters judicially and rationally."—Frank H. Probert, of Los Angeles, consulting engineer for Thomas F. Cole and engineer for the General Electric Co., has been in Butte for a week or more. He made an examination of the mines of the East Butte Co., and expressed himself well satisfied with the condition of the property, the ore in sight, and the prospects of the company. Mr. Probert also made an examination of some mines in the Corbin district.

The Snowstorm Mining Co., operating at Mullan,

Montana.

interest is crystallizing. Others are securing options and it is expected that a public knowledge of their plans will be gained within a short time.—Work on the iron and brass foundry which the Calumet & Hecla Co. is erecting at Calumet is progressing steadily. The structural steel has been completed and work can now go forward on the interior of the plant without hindrance from inclement weather during the winter.—At the Superior mine, in Section 15, south of Houghton, the No. 1 shaft has reached the fifth level and the cross-cut at that depth has encountered the Baltic amygdaloid formation about 40 ft. from the shaft. The cross-cut has not penetrated the lode as yet, but from the limited distance already entered, it is apparent that the mineralization at that depth is equally as good as it was at the fourth level. The Calumet & Hecla Co.'s option on the remainder of the treasury stock, which, when added to that company's present holdings, will give it a controlling interest, expires December 31. In view of the favorable showing at the property, it is expected that the Calumet & Hecla will exercise its option.—A large mass of native copper is being extracted from its encasing rock at the sixth level on the Branch vein in the Michigan mine, Ontonagon county. About 28 tons of copper have been cut off from the mass and the end is not yet in sight. A piece about 14 by 18 ft. and six inches thick is now being detached for hoisting. It will weigh 30 tons. There is no way of telling how much more copper remains. The Michigan mine was famous the world over in its earliest days for the masses of native copper which it yielded and they still form a large part of the output. John R. Stanton

Idaho, in which Butte men have large interests, has installed a new air-compressor with capacity to operate 30 drills. The new Riblet aerial tramway from No. 3 adit to the mill is about ready for operation, and when in working order the company will increase its daily output. It is now mining about 250 tons, which is treated in the leaching and precipitating plant. Some first-class ore is shipped direct to various smelters. Two cars of concentrate were shipped from the mill a few days ago. The assay value of the concentrate was 400 oz. silver and 47% copper. A fine chimney of ore has been opened in the vein on the 500-ft. level. The orebody is six feet wide and has been opened a distance of 40 ft. The ore assays from 21 to 40% copper. Work is about to be resumed on No. 4 adit, which was in 554 ft. when work was stopped several months ago. About 2,550 ft. more will take the adit to the vein, which it will open at a depth of about 2,000 ft. The manager, W. D. Greenough, announces that the next dividend of the company will be paid in January, and that thereafter dividends will be paid monthly.

The Lewisohns, of New York, are sinking a shaft on the Granite Mountain mining claim in North Butte. The property lies between the Edith May and the Jessie of the North Butte Co. and the latter drove three cross-cuts at different levels through the Granite Mountain without encountering any ore. The Lewisohns, however, will sink a shaft 1,500 ft. deep.—A company, called the North Butte Extension, has taken options on six mining claims in an undeveloped part of the district northeast of the North Butte mines. The claims are not an extension of the North Butte, but they lie east of the Berlin group, owned by the North Butte. The Berlin claims are undeveloped and there is no undeveloped property near the Extension claims, although the latter are located in well-mineralized territory. The company has not yet been completely organized, but its promoters are in the East, trying to interest financial men in the project.—The Parrot mine is being vigorously developed, especially on the 1,200, 1,600, 1,700, and 1,800-ft. levels. Sinking has been stopped for the present, but some fine orebodies have been opened on the 1,800-ft. level, and also on the 1,200. Mining is confined almost entirely to the levels between the 1,200 and 1,700, and only about 200 tons of low-grade stuff are being mined daily. The Parrot, however, is looking better than it has for years, and a lot of high-class ore has been blocked out. No mining of it will be done until the development work now under way is completed. The Parrot shaft is down 1,870 ft.—The Butte & Bacorn Co. has started cross-cuts from the 300-ft. station of the Coleen Bawn shaft for the purpose of tapping the veins known to exist. The company has little expectation of finding commercial ore at that depth. No cross-cutting will be done in the Calumet and Belinda until those shafts reach a depth of 600 ft. The Belinda is now down 550 ft. and the Calumet 540 ft. Three shifts of men are working in each of the shafts, and good progress is now being made.—A shoot of high-grade silver ore has been struck in the Eagle mine in the east drift of the 200-ft. level, about 165 ft. from the shaft. The ore is 18 in. wide, and assays as high as \$340 per ton.—The mines of the Boston & Montana and several of the Anaconda mines were closed for several days because the ore-bins were full and there were no cars available for transport to the smelters. The sudden cold weather froze the ore on the cars in transit and it had to be thawed out before the unloading was possible. Wrecks both on the Great Northern, and on the Butte, Anaconda & Pacific further delayed traffic.

F. A. Heinze announces that he will take up the option he has held for some time on 620,000 shares of stock in

the Stewart mine at Wallace, Idaho, and that he has the controlling interest in the property. The Stewart is one of the most promising mines in the rich Cœur d'Alene district. He secured the stock at 40 cents per share, and it is now selling around \$3 per share.—The announcement is made that the promoters of the North Butte Mountain Copper Co. have succeeded in interesting Eastern capital in their project, and that development work will be started soon. The company owns a lot of locations in the vicinity of the Butte & Bacorn mines north of Butte.—The Amazon-Butte Co. is making good progress in sinking a shaft on the Amazon claim. A portion of the company's ground has been leased to individual operators who are mining on it.—Sinking has been resumed on the West Colusa mine by the Boston & Montana Co. The shaft is 1,600 ft. deep, and it is to be sunk 400 ft. further.

Toronto, Canada.

Work on the Gillies Tract.—A New Map of Cobalt.—The Rush Continues.—British Capital Interested.—Work on the Silver Lion.—Portage Bay District.—The Silver Leaf is Sold.—A Mistaken Rush in Saskatchewan.

Willet G. Miller has returned from the Cobalt silver district, where he has been directing Government development work on the Gillies timber limit. The first shaft will be completed this week to the depth of 75 ft. according to contract, and a drift into the silver ore will then be commenced. The shaft has been sunk to one side instead of in the vein itself. The professor gives as a reason for this, that the plan pursued in most of the mines of sinking on the vein, will make them difficult to work in the winter, owing to the accumulation of snow in the ditches and trenches. By sinking to one side of the vein it is as easy to work in winter as in summer. Though the samples of ore are rich, Prof. Miller has made no assay, considering that specimens gathered promiscuously from a mine are no criterion of its real value, and preferring to wait until two or three carloads are treated. The shaft on the second vein has just been begun and will only be sunk 25 ft., as the vein does not promise nearly so well as the first. Several other veins have been discovered on the Gillies limit, but only these two will be worked during the winter.

In addition to supervising this work Prof. Miller has been engaged in re-mapping the Cobalt area on a much larger and more detailed scale than has been hitherto done, showing the leading properties, with elevations and contours. The scale will be 400 ft. to the inch, with a horizontal contour of 10 ft. to the inch.—In spite of the advance of the season the rush of investors to Cobalt during the last few days has been greater than ever. The Grand Trunk was forced to run a special train to the north one day this week when a large party came through from New York. The hotels at Cobalt cannot accommodate the visitors.

The Temiskaming & Northern Ontario Railway Commission has advertised for tenders for the mining rights on other sections of the railway right-of-way than those already leased. Three sections are offered for completion; namely, between the 90th and 95th miles; between the 95th and 101st; and between the 105th and 108th miles. The leases will be for 999 years, a cash bonus of \$1,000 per mile must be paid, and the output will be subject to a royalty of 25% of the gross value at the mouth of the mine.

A. E. Hitchcock, of London, England, has been visiting Cobalt in company with W. K. George, president of the Foster mine, and it is anticipated that the introduc-

tion of British capital to a large amount may be the result of his inspection.—At the property of the Silver Lion Mining Co., recently organized, about a mile south of Gillies station on the Temiskaming & Northern Ontario railway, a new shaft is being sunk in the vein and buildings are being erected. John Black, consulting engineer, is superintending the work.—There is a great deal of activity in the Portage Bay district in the western part of the Cobalt area and many properties in that quarter have changed hands recently.—The first carload of ore from the Green-Meehan mine has reached the New Jersey smelter and another was shipped last week. There are eleven veins on this property within an area of five acres. No. 1 vein, which has the best showing, varying in width from 3 to 14 in., has been opened up for 350 ft. A considerable amount of ore has also been taken from No. 9 vein in a cut 42 ft. long. The other veins are still intact, as accommodation for employees

Cobalt lake is surrounded by valuable properties, including the Nipissing, La Rose, and McKinley-Darragh-Savage. It is about 50 acres in extent, and four acres have been already sold to the Nipissing Co. The remaining 46 acres is to be offered for tender. Kerr lake is also close to good properties and veins are known to underlie it. The rights to 17 acres have already been parted with to the holders of adjoining locations, leaving 23 acres to be sold. The tenders must be in by December 20.

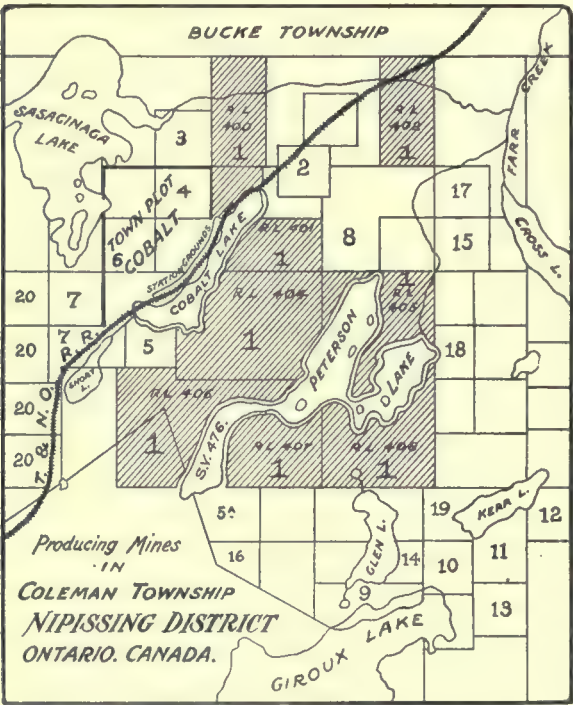

At the Northern Ontario Consolidated Copper Co.'s property near Dean lake in Algoma district a nice find of copper ore has been made at a depth of 130 ft. It assays 30% copper, together with gold and silver. The company, which now ships its ore to Illinois for treatment, has decided to build a smelter.

Cobalt, Ontario.

Great Speculative Activity.—The Green-Meehan, Temiskaming, and Evans Mines.—Wonderful Development.—New Machinery.—Rich Discoveries.—Widespread Interest in the District.

The term 'phenomenal' has been continually applied to the mining camp of Cobalt from the minute it began to attract attention; it can be truly applied to it today. From every State in the Union and from European countries men are daily coming to Cobalt. Wild speculation has begun and prospects throughout the township of Coleman (six miles square) are being sold at prices ranging from \$10,000 to \$100,000, according to their position. These in quick order are capitalized at from a quarter of a million to two and a half million dollars. Many of the rich mines cover only 20 acres. The quick transition from a mere prospect to a shipping mine and the possibility of any claim in the township proving valuable, is no doubt the cause of the willingness of investors to pay what otherwise would seem mad prices.

Take the Green-Meehan mine as an example: Two men named Green and Meehan located this 40-acre claim last year. It was then not considered favorably by any mining men in the camp and they prospected it for several months. No profitable results were forthcoming, although they did make a sufficiently good discovery to warrant the Government Inspector passing it as a valid location. When the word went out last September that they had uncovered a vein of calcite heavily shot with silver and five feet in width, the story was received with the utmost incredulity. Investigation proved its truth. An option was given a few weeks after at \$250,000, which was a fabulous price to be offered for a claim in the township of Bucke. The property consists of part of Lot 14 in the First Concession, immediately adjoining the Coleman line. The original owners were afraid to disturb the vein, fearing it would prove nothing but a blow-out. The men with the option had no such fear, and, by putting in five blasts, they got sufficient ore, running as high in value as 75% silver, to fill 250 sacks. The day their option expired they were offered \$250,000 for their bargain. They formed a company and assumed the ownership on October 23. Last week their first shipment of 20 tons of ore was made and it will run as high as \$20,000 per ton. In this short time 11 veins have been discovered and No. 1, from which this shipment was made, has been opened up 358 ft. The rich ore-shoot has been proved for a distance of over 75 ft. No. 9 has produced 12 tons of high-grade ore and this has all come from the surface; nothing but stripping has been done. The other veins are untouched and 90% of the property is still unprospected. A second shipment will be made shortly. All the veins on this and the adjoining property are in the Keewatin series of rocks and are in the same formation as the bonanza veins, No. 49 and

is limited, but since the property changed hands large camp buildings are being erected to provide for an increased force. The purchase by American capitalists of a controlling interest in the Silver Leaf mine, comprising 40 acres in the Kerr Lake district, will result in the complete reorganization of the company and its operation on a considerably more extensive scale than hitherto. The vein so far worked is an extension of the Lawson vein.

The statement that the Ontario Government had been offered \$15,000,000 by a strong financial syndicate for the mining rights of the Gillies timber limit is positively denied by Premier Whitney.—Later reports from the West state that the reported gold strike at Birling, Saskatchewan, is without foundation. There was a short-lived rush to that locality, but the only mineral found was iron pyrite.

The Provincial Government is about to offer for sale by tender the right to mine the beds of Cobalt and Kerr lakes. Two sets of claimants recently attempted to locate the bed of Cobalt lake, but their claims were disallowed.

50, on the Nipissing. New buildings are being erected. Fifty men are now employed and this force will be doubled as soon as the buildings are completed. The working shaft, which will be a double-compartment, has been started. A 200-h.p. boiler, steam, and air plant is to be installed before Christmas. Charles A. O'Connell, who has mined on the Mother Lode in California, is the new superintendent. Mr. O'Connell came to Cobalt over a year ago and was with the White Silver Co., operating the Hargreaves mines. They have 300 acres in the township of Coleman but are tied up in litigation with the Ontario Government. The Green-Meehan Co. has refused an offer of \$1,500,000 for this property for which, four months ago, no one would have given \$50,000.

Adjoining this property is the Red Rock, formerly owned by the Messrs. McMartin, Timmins & Dunlop. This is now controlled by a New York and Pittsburg syndicate, headed by Q. W. Beese. They have a continuation of the Green-Meehan vein, and a new vein has been discovered full of argentite which at surface is as much as five and six inches wide. Some sensational shipments are promised in this quarter too. Nine miles further south in the Portage Bay district a shipping mine, the Evans, has caused a great increase in the values of claims there. Cobalt and the shipping mines O'Brien, Nipissing, Silver Queen, Tretheway, Buffalo, McKinley-Darragh-Savage, and La Rose are about in the centre of a line drawn from the Evans to the furthest shipping proposition in Bucke. The extension of the camp in all directions is now an accepted fact.

The Temiskaming down below Cross Lake is another new proposition whose history while not quite as sensational as the Red Rock's or the Green-Meehan's, has nevertheless been exceedingly interesting. As far back as last May the camp was told that at a depth of 40 ft. a good vein of native silver had been found by two prospectors named Cartwright and Richardson. Their claim had passed inspection and they had a surface vein of nicolite and cobalt. Sinking their shaft right on the vein, it gradually widened and at the 40-ft. level native silver was found. These properties are mentioned by me because they afford undeniable evidences that the area of the rich mineral zone is much larger than originally considered possible. It is true that the number of shipping mines has not materially increased in the past six months. The Green-Meehan and the Evans are the two new ones of recent date. The Temiskaming and Red Rock will shortly be added and there will be a wait probably of some months before any others begin to ship. Deeper development will be necessary in the initial stages but the existence of rich ore deposits is established.

The old mines are increasing their staff and putting in more machinery and installing better plants. At the Foster three steam hoists, two boilers, and a 12-drill compressor from Allis-Chalmers are to be installed and whistles will be blowing in December. A. W. Scott is superintendent here.—At the Tretheway some extra machinery is being ordered.—The Townsite Mining Co. is adding a steam boiler, hoist, and a six-drill compressor and four drills from the Rand-Jenckes. They are sacking ore.—The Right-of-Way Mining Co. is going to make its first shipment next week and some of the ore runs as high as 5,000 oz. silver per ton.

Up the Montreal river at the Edison mine, the superintendent, Horace M. Wilson, reports that they are getting into a good body of ore. They are sinking their shaft right on the vein and are down to 60 ft. The vein is getting wider and they have riders of smaltite six inches wide. A tunnel is being driven from a point in the hillside to strike the shaft at the 60-ft. level which will enable them to run the ore right out and save that 60 ft. of hoist-

ing, as they propose to continue the shaft to a depth of 200 ft. They have a 60-h.p. boiler and an air compressor and three air-drills made by the McKiernan Drill Co., of New York. A visit has been expected from Thomas A. Edison, who owns this property, for several months but it is not likely now that he will be here until after Christmas.—The working developments at both the old and new properties in this camp will be closely followed and reported weekly.

Salt Lake City, Utah.

Local Business.—Interest in Nevada Copper Districts.—The Smelter Smoke Controversy.—Heavy Snowstorms Block Traffic.—Progress at Bingham.—Output of Tintic.—Important Transfer.

Last week's ore and bullion settlements reported through Salt Lake banks reached the total of \$741,689.—A great deal of local interest is being manifested in both the Ely and Yerington copper districts in Nevada. Several new companies have been formed here recently to operate in both camps. Samuel Newhouse and associates have formed the Western Nevada Copper Co. to operate in the Yerington district. In the same locality the Nevada Douglas, of which W. C. Orem, of Salt Lake, is manager, is planning vigorous exploration.

The application of the attorneys of the several smelting concerns, which were defendants in the smoke cases brought before the Federal Court for a re-hearing, has been denied, so an appeal to the Circuit Court of Appeals at Minneapolis has been taken. Pending the settlement of the controversy before that tribunal, the plants will continue in operation as usual, after having given bonds as a guarantee to the farmers against damage. All the smelting concerns affected by the injunction of Judge Marshall are planning to remove to some other site. It is not unlikely, however, that the Utah Consolidated will move its smelter to the camp of Bingham, following the example of the Yampa Smelting Co. —The fact that the control of the Ohio Copper Co.'s mine has passed to F. Augustus Heinze has been officially announced, but there has been no change in the management, as yet. It is rumored that Mr. Heinze has a call on the Fortuna mine, also at Bingham, yet it is hardly likely that it will be exercised pending the matter of a new site for the smelters at Bingham Junction and Murray.

The Silver King Consolidated Mining Co., at Park City, has closed a deal for the purchase of some adjoining property, which will give this company a territory of 500 acres.—The Daly-Judge Mining Co. is preparing to equip its mine with an electric-haulage system.

Heavy snowstorms at Bingham have put a stop to steam-shovel operations of the Boston Consolidated. This company, as also the Utah Copper, has been using shovels to strip the overburden from the low-grade porphyry ores.—The Utah Apex Mining Co., of Bingham, is shipping 50 tons of ore to the smelters and this tonnage will be doubled in December, at which time the new aerial tramway will be ready. The tram will bring the ore from the mine to a point in Carr Fork cañon near the entrance to the Parvenue adit, where a large ore-bin has been built. Pending the construction of the spur from the track of the Copper Belt railroad to the bin, ore will be hauled down the cañon to lower Bingham for loading onto the cars of the Rio Grande Western for shipment to the Garfield smelter.—The construction of the mill of the Markham Gulch Milling Co., in lower Bingham, which is owned jointly by the Utah Apex and Utah Development companies, is progressing, and an official of the company states that the plant will be ready within 90 days. The Utah Development Co. is shipping ore to a custom mill in the camp at the rate of 1,000 tons per month.

The United States Smelting, Refining & Mining Co. has secured an option on the West Mammoth and Golden Ray claims, adjoining the Centennial-Eureka mine at Tintic. There are thirteen claims. The development of the ground will begin at once and will be conducted through the Centennial-Eureka mine. The bond price is said to be \$162,000.—The ore shipments from the Tintic mining district last week amounted to 154 carloads, the contributing mines and amounts being: Ajax, 5; Bul-lion Beck, 6; Beck Tunnel, 9; Black Jack, 1; Centennial-Eureka, 47; Carisa, 10; Eagle & Blue Bell, 10; Eureka Hill, 6; Gemini, 10; Grand Central, 6; May Day, 2; Mammoth, 14; Sacramento, 6; Uncle Sam, 3; Victoria, 3; Yankee Con., 7; Tintic Iron, 8; Swansea, 3; other mines, 2 carloads.

London.

Record Output in the Transvaal.—Dull Share Market.—The Gold Fields Report.—The Question of Secret Reserves.—Gold Production in India.—Deep Lead Companies. More Capital Required.—Big Undertakings.—Mining on the Yukon.—Much Improved Prospects.

The Boer filibustering expedition into Cape Colony from German West Africa, has made no impression on the Kaffir market. Nothing does nowadays one way or the other. Even another record monthly output—540,609 oz.—has had no effect, except, perhaps, to produce a slightly more hopeful feeling with regard to the future. The adverse causes still existing in the Transvaal are strongly reflected in the Consolidated Gold Fields' annual report. Owing to the severe and sustained fall in South African stocks, the directors state they have had to make provision for depreciation in respect of some of the company's investments which stood in the books at a cost in excess of their market quotation. The realized net profit on the year's operations, which is largely derived from dividends received on investments, after deducting debenture interest and all outgoings, shows a balance to credit of £409,469, from which the dividend on the preference shares, income tax and French Government taxes have been provided, leaving £323,240, which, added to the sum of £934,687 brought forward from last year, produces £1,307,928. From this the directors have made provision for the depreciation referred to above, amounting to £700,000, leaving £607,928 to be carried forward to the credit of the current year's profit and loss account. Investments stand in the books at average cost or under, and all shares are taken into account at prices below those current at the date when the accounts were made up, and show on current prices a further large unrealized profit. The directors consider that had the outlook, as regards unskilled labor been free from doubt, they could have safely recommended a distribution; but until all doubts are removed as to an adequate supply of unskilled labor, more particularly in the case of companies having commitments in respect of debentures for which the Gold Fields company has assumed liability, they hesitate to recommend a course that would diminish the company's cash resources. Should, however, the policy of the Transvaal Government, as regards unskilled labor, dispel this doubt during the current fiscal year, and be authorized by the British Government, they would consider themselves fully entitled to distribute an interim dividend.

Incidentally, the 14,968 oz. included in the Transvaal output for October from mines which have abandoned the 'equalizing system' may be mentioned as a step in the right direction. The hope may be expressed that the practice of 'secret reserves' will be dropped by all self-respecting companies. All well-established mines, that is to say, those possessing ore reserves blocked

out for a recognized period in advance of the ordinary milling capacity, can afford to publish the true month's yield of precious metal and show the fluctuations inherent to the character of each mine respectively. Any other course is a proof of pandering to Stock Exchange vagaries which should not be allowed to come within the scope of a mine manager's functions. What would be thought of an executive at the head office in London who adopted the practice of locking away a large sum of cash out of sight from the company's auditors so as not to include it in the assets at the end of the financial year? This may be thought perhaps as putting the case too strongly, but what is wrong for a public company's officials at one end cannot be right for those at the other. Besides, in the event of discovery, public confidence, at best not overstable in the matter of mining, receives a shock. Not so very long ago a leading gold mine's return for a given month was found to show an important increase on the usual average. A scramble for the shares ensued, with the result that when the 'secret reserve' cat was let out of the bag much lurid language was let loose on the particular management, and mining methods in general came in for scornful denunciation.

The news from Loddon Valley Goldfields is somewhat disconcerting to stockholders who expected by this time to learn that payable wash had been reached. According to a report from the general managers it appears that the wash has been entered about 25 ft. to the west of borehole No. 67. The bedrock at this point is smooth and hard, and dips at a high inclination—upwards of 45° east. They are also opening up at borehole No. 81, and will enter there in about a fortnight; they are also driving north from borehole No. 70. The water has not given any trouble. The steep dip of the bedrock at the point entered indicates that the auriferous channel lies further to the east, and that it will not be possible to form any judgment of the value of the wash until the work in progress in this direction has been done. Immediately following on this deferring of hopes in the case of Loddon Valley, the circulars issued by the boards of the Victorian Deep Leads, and the Moorlort Goldfields, announcing reconstruction schemes with a view to the provision of further capital for the energetic conduct of pumping operations, have not been welcomed with enthusiasm by the market. In the case of the Victorian Deep Leads, the new company is to have a capital of £400,000. The shareholders in the old company are to receive 200,000 shares, or five shares in the new company for every eight shares in the old company; 100,000 further shares in the new company are to be issued at par, and shareholders have the right to subscribe *pro rata* for these shares, according to their holding. The remaining 100,000 shares are to be kept in reserve for future issue. The new Moorlort Company is to be formed with a capital of £275,000. Shareholders are to receive 100,000 shares, or five shares in the new company for every eight in the old company; 100,000 further shares in the new company are to be issued at par, and shareholders are to have the right to subscribe *pro rata*. The remaining 75,000 shares are to be kept in reserve for future issue. In both cases the issue of the new capital to be paid for in cash has been guaranteed in consideration of an option on the reserved shares. Loddon Valley Goldfields, Ltd., has itself a capital of £240,000 in £1 shares fully paid. The area owned covers 5,680 acres. Another of the Victorian deep-lead companies under the management of Messrs. Bewick, Moreing & Co. is the Australian Commonwealth Trust, with a capital of £250,000 in £1 shares, formed to undertake financial and other business and to secure co-operation in the development of deep-lead mining. Interests have been acquired in the

Berry United, Great Berry, Loddon Valley, Moorlort, Option Blocks, and Victorian Deep Leads. The company owns the Avoca and Archdale leases, comprising nearly thirty miles of lead, and the country adjoining the Victorian Deep Leads to the north for a run of about ten miles. It is entitled to 20% of the profits of the Loddon, Moorlort, and Victorian companies for about ten years and has the right to float off subsidiaries of the Victorian Deep Leads, Ltd. The Consolidated Deep Leads, Ltd., with a capital of £200,000 in 4s. shares, fully paid up, is in the same category. The area owned covers 2,500 acres, known as the Option Blocks, but the company is interested in the Loddon Valley and Moorlort companies, in both of which it has substantial holdings, as well as in the Australian Commonwealth Trust. The length of the property owned by the company is about two miles.

Cripple Creek, Colorado.

New Air Compressors.—The Drainage Adit.—Financial Support for It.—Strikes in the Aileen and Longfellow.—A Flat Vein in the Rebecca.—Aerial Tramway.—Several Interesting Developments.

The 10-drill compressor ordered from the Chicago Tool Co. by the Bull Hill Mining & Development Co. for use on the Cresson mine, on Raven hill, has arrived in the district and will shortly be ready for use. This compressor is to be run by electricity, the motor being already on the ground.—A new 30-drill compressor is soon to be put in by the El Paso Gold Mining Co. on Beacon hill. This piece of machinery is to take the place of three 10-drill compressors, which are now in use.—The Smith & Altman lease on the Doctor-Jack Pot mine is shipping a good tonnage of ore from the new strike on the 700-ft. level. Returns as high as five ounces in gold have been obtained.

The old stopes on the 100-ft. level of the Wild Horse mine, situated on Bull hill, of the late United Gold Mines Co., are being gone over by Thos. Reynolds, who has obtained them under lease. Rich ore was shipped from these stopes in the past, and Reynolds is obtaining a small tonnage of very rich stuff by picking and sweeping. On the 500-ft. level of the same mine, Oscar Fogelman & Co. is shipping ore from a 12-in. streak, which gives returns of two to three ounces.—The Colorado State Investment Co., operating the Aileen mine on Guyot hill, is shipping ore mined from the 600-ft. level. The average returns run in the neighborhood of an ounce, but the last car was of a better grade, yielding over \$40 per ton.

It has now been practically settled that the deeper bore, or Window rock scheme, will be chosen for the new drainage tunnel for unwatering the mines of the district. The Strong Gold Mining Co. is said to have come in and is willing to subscribe to the drainage project. Liberal subscriptions have also been promised by the Golden Cycle Co., representing also the United Mines Co., as well as the Stratton Estate and Ophir mine, the latter having come into much prominence of late. The water in the Gold Coin shaft of the Granite Co., where pumping was stopped not long since, is rising gradually and is now above the 1,000-ft. level, cutting off all work below this. It has also risen in several of the adjacent mines, and goes to show that a drainage adit would be of great service to such properties as cannot afford to continue their pumping operations.—A good vein has been encountered at a depth of 300 ft. in the Midnight shaft of the Longfellow claim. This claim belongs to the Stratton Estate, and is situated on the south slope of Bull hill; it is being operated by the American Leasing Co. It is supposed that this vein is an extension of that which has

produced so well of late in the Specimen and Sacramento claims, under lease to the Western Investment Co.—Promising results are being obtained by B. Von Phul and partners, who are operating on the Fairchance claim on Gold hill. These men are sub-leasing from J. C. Kellogg, who has this property under lease from the Vanderbilt Estate.

Good ore has been encountered on the Rebecca mine at the head of Poverty gulch. Brown, Hill & Winters are working at a depth of 250 ft. through the fourth level of the C. O. D. shaft. It is a flat vein, averaging nearly 3 ft. wide. This strike was quite unexpected, being made while cross-cutting for a perpendicular vein cut some months ago in a 40-ft. shaft west of the C. O. D. shaft. The latter vein should be cut within 10 ft., and it is hoped that at the junction of these two veins rich ore may be obtained.—J. W. Price has sold his interest in the Price-Waters lease on the Last Dollar mine, situated at the foot of Bull hill, to J. H. Waters. Work will be carried on as usual and regular shipments made as before. The lease is said to be making good money.—An aerial tramway is nearing completion, from the ore-

Map of Southwestern Colorado.

house at the entrance to the Moffat tunnel to the F. & C. C. Railroad, a distance of about 1,000 ft. It is to handle the output of the Little Clara claim of the Work property, and will have a capacity of approximately 160 tons per day. The siding at the terminal will accommodate eight narrow-gauge freight cars.

Operations have been resumed on the Jo Dandy mine on Raven hill. A 30-ton car of ore is being shipped every day to the Standard plant at Colorado City. J. P. Snyder, T. E. Fuller and associates, leasing between the 200 and 400-ft. levels of the Davenport shaft of the Doctor-Jack Pot Co., have struck some good ore. An 18-in. vein has been encountered on the lower levels, from which assays up to as high as five ounces have been obtained.—The Standard Development Co., operating in the South Burns of the Acacia Co. on Bull hill, has encountered some rich ore in a stope on the 800-ft. level, situated 50 ft. north of the shaft. The vein varies from one to three feet wide, showing sylvanite and rusty gold in several places. Three cars per week are being shipped from this lease, giving returns from \$20 to \$50 per ton.—Another promising strike has been made on the Black Jack property operated by the Union Leasing Co. Cross-cutting has been going on for several months at a depth of 400 ft., and the vein now cut is thought to be an extension of the Lonaconing.

Mining Summary.

ARIZONA.

COCHISE COUNTY.

The famine of sulphide ore which has handicapped operations at the Old Dominion smelter in the past, has been relieved by the arrival of eight cars of such ore from Cananea and Nacozari, Sonora. The company expects to receive a sufficient supply to enable it to continue smelting with four furnaces until the end of the month. The lack of storage for fuel-oil caused by the scarcity of tank-cars in the Southwest has made it necessary for the company to revert to coal, of which a supply is now on its way from the Dawson mines in northeastern New Mexico. The sulphides from the company's own mines have increased in quantity, shipments from the Continental averaging 65 tons daily. The development of sulphide ore on the lower levels of the Globe, the principal mine of the Old Dominion, is satisfactory. The west drift on the 14th level continues in sulphide, improved both in extent and quality, and the corresponding drift on the 13th level is also in good concentrating ore.

GRAHAM COUNTY.

A new strike has been made on the copper claims of the Gold Belt Development & Reduction Co., situated near Morenci. A tunnel is being driven into the hill above the original location, and recently ran into a three-foot vein of carbonate ore assaying 12% copper.

MOHAVE COUNTY.

Electricity is to supplant gasoline at the Gold Road mill and for the hoists at this company's mines. As soon as this change has taken place the Billy Bryan shaft will be sunk to the 1,000-ft. level, and the capacity of the big mill greatly increased. The initial station at Kingman is to have a capacity of 2,400 h.p., more than 500 h.p. of which will be used by the Gold Road Co. alone. The machinery will be on the ground within 60 days. — A mill is to be erected at the Gold Valley mines, near Silver Creek, to work ores from these properties. Some rich ore has been opened up. A big plant has been purchased, and the shafts will be sunk 500 ft. or more. — The machinery for the mill to be erected on the Tiburcio mine (formerly the Berkeley), is being fast assembled on the property. The mill is to have 25 tons daily capacity, being fitted with Cornish rolls and Standard concentrators. A big tonnage of ore is on the dumps, and as soon as the water is pumped from the mine the reserves in the old stopes will be broken down and milled. — A fine body of ore has been found at the Cupel ground, on Stockton hill. A shaft is being sunk on the orebody, which is found to increase in width as depth is gained. This ore runs high in lead, and contains a little silver.

CALIFORNIA.

AMADOR COUNTY.

Negotiations which have long been pending for the sale of the Wildman-Mahoney mines, near Sutter Creek, have resulted in the transfer of the property to W. J. Morphy from the owners, Messrs. Bishop and Spring of San Francisco, who had acquired title through the foreclosure of a mortgage a few months ago. With the purchaser are associated a number of Eastern capitalists, and it is stated that development of these mines will be undertaken on a big scale in the near future. It is not at present known what disposition is to be made of the large indebtedness standing against the mine for wages and material.

BUTTE COUNTY.

A deal has been closed whereby D. M. Shanks and D. Marsh, of Los Angeles, obtain possession of several hundred acres of mining ground along the banks of Butte creek, from 8 to 12 miles above Chico. Dredges are to be used. The endeavor to interest capital in this ground met with poor success for two years, although at one time a syndicate was in process of formation to handle the whole district. This fell through, and W. P. Hammon on investigation some years previously declared the general contour of the country too rough to work with the immense dredges in use

at Oroville. A new dredge designed to work in rough country has been found to operate successfully, costing but \$15,000. These dredges will be equipped with electrical shovels. The work of building cottages for employees will commence within a few days.

LOS ANGELES COUNTY.

T. S. Rodgers, a mining engineer of Los Angeles, has just returned from Antelope Valley and the eastern slope of the Sierra Madre mountains, in the northern part of Los Angeles county, where he has been examining mines for the Original Golden West Mining Co. He reports a heavy snowstorm, and a fall of three feet in 36 hours. He and his men were snow-bound for four days in Deadman's cañon, and barely escaped freezing to death. This is said to be the earliest storm in that part of the country for twenty years.

MONO COUNTY.

The Pittsburg group of mines situated on Masonic creek, near Bodie, has been sold to S. Brougner and E. Shaw, both of Tonopah, by Messrs. Phillips, Dorsey, and Bryan, who have held the controlling interest since the incorporation of the properties. The Tonopah purchasers have also bonded the True Friend and other claims in this district. The erection of a 10-stamp mill will be commenced immediately, and a 40-stamp mill will be built should the mines prove permanent. The water-rights on Masonic creek were purchased from Harvey Boone Jr. and associates.

NEVADA COUNTY.

(Special Correspondence).—There is much activity at Deadman's Flat, in the Rough and Ready district, $3\frac{1}{2}$ miles southwest of Grass Valley. This barren country has been known to contain auriferous deposits since the days of the early gold-seekers, but it is only recently that the camp has come into prominence. Within the past few months practically the entire district has been acquired by large financial interests, and a boom is fairly on. A number of rich strikes has intensified local interest, and it is predicted that Deadman's Flat will develop into a great mining centre. The veins, which have a northerly strike, with a westerly dip, occur in a diabase formation, in the amphibolite area between two belts of gabbro. The ore is usually of a dark color, the grain varying greatly, and inclusions of unaltered country often occur in it. The richer lodes are small, usually about two feet wide. Two large veins of white quartz about 25 ft. wide exist, but they do not carry sufficient gold to be profitably worked. The principal mines of the district are the California, Kenosha, West Point, Glendora, and Normandy, of which the California and Kenosha are the most extensively developed. Particular interest is manifested in the Glendora and Normandy groups, both of which give every indication of developing into good mines. Bullion from this district has exceeded 900 fine, which augurs well for successful milling. The Glendora Co. owns 1,500 acres, and has five highly mineralized lodes, the largest and richest being the Glendora vein, with an average breadth of two feet. This lode has a perpendicular dip, its strike being north and south. A double-compartment vertical shaft 50 ft. deep has been sunk on the Glendora claim, while five smaller shafts tap the orebodies at other points. Development work is being pressed vigorously, and it is intended to erect a modern 10-stamp mill and power plant when the mine is ready for them. The ore has an average value of \$35 per ton. The Normandy mine comprises three claims, traversed by three small highly mineralized veins, with a WSW strike and a dip about 40° west. The two lodes are 41 ft. apart and 8 in. wide. They are rich, the ore being found in a diabase. A small percentage of sulphides is found with the coarse gold. The West Normandy is a cross-vein with a northerly dip. A double-compartment shaft will be immediately sunk to a considerable depth and a large area of territory developed. A modern plant will be placed on the property as soon as the progress of the mine renders this advisable.

Grass Valley, Nov. 27.

An important deal has been closed on Deadman's Flat, the Normandy group being purchased by Chicago operators, to be worked as one of the properties of the Normandy Keystone Gold Mining Co., with Frank Dulmaine as super

intendent. Horace Jones will act as manager. Ground has already been broken for a new two-compartment shaft to be sunk on the Dulmaine claim, one of the Normandy group, at a point which will permit the development of the whole property, which has a well-defined vein with ore-shoots several hundred feet long. The indications at Normandy have always been good, the surface workings having proved rich, but the claim has never been worked below water-level. A number of other mines have been opened or resumed operations in this district lately, including the California, Kenosha, West Point, and Glendora.

SHASTA COUNTY.

Rich copper ore has been found in the Mountain Monarch mine on Clear creek, three miles west of Shasta. This discovery has necessitated a change in the plans of the management, the mine having always been regarded as a gold proposition and worked on that basis. With the advance of the adit the ore has been found to carry an increased percentage of copper, until it has become necessary to abandon a plan to erect a stamp-mill and cyanide plant. The ore will be shipped to the Kennett smelter until the Keswick plant starts up again.

TUOLUMNE COUNTY.

(Special Correspondence).—Grading for the mill to be erected on the Patterson mine, near Tuttletown, has been completed; but as the machinery is not expected for some time yet, work has been suspended. Development work is being continued, however, in the same active manner as usual.—The Atlas mine, on Jackass hill, is bonded to Ross Bros., of Copperopolis.—Work has been resumed at the Mazeppa mine, which adjoins the Jumper on the south. The shaft, which is 800 ft. deep, is being repaired by a small crew, which will be augmented shortly. The Mazeppa has been idle for a long time, although it is considered a promising mine. There is a 10-stamp mill on the property. C. T. Lillard, of Los Angeles, is having some development work done on a copper mine situated on the Mackey ranch, near Jamestown.

Tuolumne, Nov. 27.

SIERRA COUNTY.

A survey has been made for an electric line from the Rome power-house on the South Yuba river to the Alaska mine at Pike City. The track will be over ten miles long, and will take an air line from point to point, crossing the hills near Cherokee, thence to Badger hill, and down to the Middle Yuba river. The building of this line will give many properties in the district a chance to get cheaper power. The management of the Alaska mine has already made arrangements to obtain power from this line, supplanting the use of steam.

TRINITY COUNTY.

The entire group of mines on Buckeye mountain has been bonded by Lincoln Brodt, representing foreign capital. These gravel mines were owned by the Humboldt Mining Co., and the group comprises one of the largest deposits in the county. Owing to lack of water, the present company was unable to work the deposit to any advantage, but the new syndicate has secured a second water right on Stewart's Fork.

YUBA COUNTY.

The Brown's Valley and Smithville districts are experiencing a great revival of mining, extensive operations being carried on in the vicinity of Clipper Mills, while at Challenge a number of old mines are being re-opened, and new prospects developed. The American Flag group, three miles east of Camptonville, is being developed systematically, the tunnel is in more than 180 ft., and some of the ore taken out assays in the thousands. At present the owners are at work upon a new adit 1,300 ft. below the first.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—Silver Creek is enjoying a return of old-time activity by reason of the increased output from the Jo Reynolds mine, and the large amount of work now being done by the Two American Sisters Co., R. B. Morton of the Jo Reynolds Mining Co., has secured a bond on

the Commodore Tunnel Co.'s property at Lawson, on Clear Creek about a mile from his mine. There is a large steam-plant and a 15-drill compressor on the Commodore property, and from this an air-pipe will run to the Jo Reynolds to furnish power during the winter months. The pipe will be utilized in summer to convey air to the Commodore, the former having good water-power nine months in the year. The present output from the Jo Reynolds mill is three carloads of concentrate per week. The company will work some of the old producers on Elephant mountain, such as the Boulder Nest, by means of an eastern lateral from the Commodore main adit, which is in 2,600 ft. At the Two American Sisters a new shaft-house is in course of erection and grading for the foundation of a mill with a daily capacity of 50 tons is progressing rapidly, most of the machinery and lumber being on the ground. A 16-drill Rand compressor has been ordered and preparations are being made to erect it. Jack Simmer, of Georgetown, is in charge of construction. J. J. White, the well-known attorney of Georgetown, is general manager for the company. Good ore has been encountered in the lowest level from the shaft and it improves as driving progresses, a second shift having just been put to work. The mill is intended to handle the ore from the dumps of the seven adits as well as the old stope dirt; these average \$7 and \$14 per ton respectively. The machinery throughout will be operated by electric power generated by the company's plant of 600 h.p. now almost completed on the banks of Clear creek, about a mile and a half below Georgetown; there is ample water to run ten months in the year. An auxiliary steam-plant will be used to run the other two months.—On the Nabob mine higher up Silver creek a contract has been let to drive the main adit 100 ft.; it is now in 1,800 ft. with a small vein of gold stuff.—A strike of ore three feet wide has just been made in the Phillips drift 2,800 ft. from the portal of the Burleigh adit on the Dives-Pelican mine. Assays run from 50 to 70 oz. silver per ton, with 50% lead.—The old Whig property on Democrat mountain has been re-opened by Georgetown parties under lease and bond. Upon cleaning out the upper adit 10 in. of ore assaying 10 oz. silver per ton and 40% lead was disclosed. The lower adit will be driven ahead 100 ft. to cut this ore 200 ft. deeper. This property has not been worked since 1877.—A. A. Ireland, manager for the Wankeegan Mining Co., has resumed work on the mine and has sent in men and supplies for the winter. Assays of some specimens from the lower adit returned 4,200 oz. silver per ton.—Work which was suspended for a short time on the Pueblo on Griffith mountain is again going forward; the adit is in 1,000 ft. and for over 200 ft. there is 12 in. of ore showing copper pyrite, galena, and blende.—The work of cleaning out and re-timbering the adit on the Golden Eagle, adjoining the Comet mine, has been commenced.

Georgetown, Nov. 23.

(Special Correspondence).—The old Kelly tunnel property is again being operated under the name of the Democrat Mountain M. & T. Co., with Jerome Smith as manager. This company is erecting a new mill, which will have a daily capacity of 50 tons. An aerial tramway is also being built to transport ore from the Moline adit. Ore will also be brought from the Belcher and Boston lodes. Water for the mill will be supplied by a Demming triplex electric pump. The pump has a capacity of 800 gal. per minute. Water will be pumped about 600 ft. Hendrie & Bolthoff, of Denver, have charge of the construction work of the mill and also furnished the machinery, which consists of jigs and Card tables, also crushers and other machinery.

Georgetown, Nov. 24.

(Special Correspondence).—The old Mayflower mine just above Idaho Springs is under bond and lease to J. T. Keegan and Ben Stanley Revett. These well-known mining men have started systematic development work on the property. They will install a large air-compressor and boiler and small machine-drills. A new hoisting engine will be added and the shaft will be sunk 500 ft. deeper. An excellent showing has already been made in the property, and Keegan and Revett are quite elated over the prospects.

Idaho Springs, Nov. 24.

Personal.

D. A. LOUIS is in Egypt.

THEODORE DWIGHT is at Guanajuato.

BERNARD MACDONALD is visiting New York.

L. M. TERRY has returned to New York from Mexico.

ROWLAND C. FIELDING is examining mines in Colombia.

H. W. EDMONDSON is now at Aguatos, in Chihuahua, Mexico.

I. ROSKELLEY has left Johannesburg and is now at Truro, in Cornwall.

CHARLES A. GREEN visited San Francisco from Mill City, Nevada.

HENRY E. WOOD, of Denver, is on a visit to Siskiyou county, California.

R. H. CHAPMAN, of the U. S. Geological Survey, is at Las Vegas, Nevada.

WALTER H. WEED is examining mines in British Columbia and Alaska.

F. W. GREY, manager of the Hutti gold mines, in India, is in England on leave.

DAVID H. LAWRENCE, of Denver, is examining mining property in the Black Hills.

H. C. BAYLON has been appointed manager of the Troitzk gold mines, in Siberia.

HUDSON H. NICHOLSON, of Chicago, has returned to Nevada, on professional business.

JAMES W. MALCOLMSON has finished his examination of the Sirena mine, at Guanajuato, Mexico.

DONALD F. CAMPBELL is engaged in the examination of the Bighorn mine, in southern California.

C. COLCOCK JONES has returned to Los Angeles from two months' professional work in Idaho and Utah.

JOHN M. BECKWITH has arrived at Buenos Ayres, where he is manager for the General Mining Company.

F. W. BOSCO has resigned as superintendent of the Mogul mill near Silverton, Colo., and returned to Denver.

PHILIP ARGALL and JAMES A. MCCLURG, of Denver, visited San Francisco on their way from Arizona to Nevada.

ALTON L. DICKERMAN is examining mines in the San Juan region of Colorado. He will proceed shortly to Cobalt, Ontario.

C. W. MACARTHUR has returned to Denver from Silverton, where he had charge of construction work at the Gold Prince mill.

FRANK H. PROBERT is examining mines at Butte, Montana. He will return to Los Angeles during the early part of December.

VICTOR G. HILLS has been examining tungsten properties in Boulder county and doing professional work at Central City, Colorado.

E. S. WARD and W. S. BROWN have opened offices at 417 Boston Bdg., Denver, where they will do consulting and engineering work.

MARK L. REQUA has resigned as president and general manager of the Nevada Consolidated Copper Co. and POPE YEATMAN succeeds him.

FRANK P. SWINDLER has been appointed general superintendent of all the Utah mines which F. Augustus Heinze controls. This includes the Bingham Con., as well as the Western Utah Copper Co., in the Deep Creek district.

ROBERT MCF. DOBLE, of Colorado Springs, formerly of Francisco, has been retained as consulting and supervising engineer by Curtis & Hine, general managers of the recently organized Central Colorado Power Company.

W. R. WARDNER has been appointed general superintendent for the Bamberger De Lamar Gold Mines Co., at De Lamar, Nevada, succeeding GEORGE E. METZ, resigned. Mr. Wardner was formerly superintendent for the Mono Mining Co., at Yreka, California.

Obituary.

R. G. HART, one of the best known mining men and operators in California, died in the City of Mexico on Sunday morning, November 18, the body being shipped to his home in Berkeley. Mr. Hart for many years operated the Texas and Georgia mines, now known as the Texas Consolidated, at Old Diggings, Shasta county. He was the original operator of the Bullychoop and the Central mines in the same district, in which properties he is reputed to have lost a fortune. He was a brother-in-law of W. J. O'Donnell, of the Quartz Hill mine, near Redding, the two having married sisters. Deceased was a native of Cornwall, England, and a mining engineer of some repute. He was approximately 70 years old at the time of his death, and leaves a family of grown children, by his first wife.

Commercial Paragraphs.

THE LANCASTER FORGE & BLOWER Co., of Buffalo, N. Y., has issued a 20-page folder describing their blacksmith equipment.

THE WELLMAN-SEEVER-MORGAN Co. has issued an attractive booklet illustrating the scope of its business in mining and power machinery.

THE SULLIVAN MACHINERY Co. issues Bulletin 51-D, describing their pneumatic hammer-drills, as used for quarrying and contracting work.

THE main sales office of THE MIDVALE STEEL Co. is now at the corner of First and Folsom St., San Francisco. This office will be retained until the Rialto Bdg. is reconstructed.

JOHN A. TRAYLOR MACHINERY Co. is moving its offices from Blake St. to 17th & Glenarm St., opposite the Denver Club, in the building recently occupied by the C. W. Knox Machinery Company.

THE BUFFALO FORGE Co., of Buffalo, N. Y. has received a large order for a complete forge shop equipment to go to Samatra. All the forges will be equipped with the down-draft smoke-exhaust system.

THE INGERSOLL-RAND COMPANY, of New York, issues Bulletin No. 2,011, describing the Little Jap hammer drill. This machine has become widely used for the lighter work of rock excavation, both at surface and underground.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

FOR the pins used in the buckets of dredges, manganese steel has proved to be best.

POWDER should never be taken into mines on cars propelled by electricity. In case of a wreck the live wires are apt to come in contact with, and set off, the powder.

STIBNITE, the antimony sulphide, has been found deposited by the hot waters that permeate the gravel at Steamboat Springs, Nevada.

THE old mining districts of Pachuca and Real del Monte in Mexico resemble, in a geological way, the gold-fields of Tonopah and Goldfield.

THERE are grounds for believing that beneath the Tertiary volcanics of Tonopah, there is an older formation of Paleozoic limestone and intrusive granite.

THORITE, the silicate of thorium, recently found in quantity in Ceylon, is likely to replace monazite as a source of thorium. It occurs in small brown cubes resembling altered pyrite.

IT IS PROBABLE that the mineralizing agents that made the ore at Tonopah were thermal waters, such as are usual among the after-effects of volcanic action; also that they were hot and ascending.

THE custom of debiting mining machinery to capital account so as to increase apparent profits is like transferring money from one pocket to the other, in the confident belief that there has been an increase of receipts.

THE most important veins of the Tonopah district are in the early andesite and do not extend into the overlying rocks. Where the early andesite is not exposed at the surface, the later rocks form a capping to the veins.

UNDER CERTAIN CONDITIONS, the rate of dissolution of gold by chlorine and bromine is reduced by the addition of 10% of silver to the gold, and the action is almost stopped when the silver amounts to 30 or 40% of the alloy.

WHERE compressed air is carried through pipes into a mine, it should be remembered that in case of fire these pipes can be utilized to carry water. Also, in case of an explosion, it is sometimes possible for the men to secure air through the pipes.

VOLCANIC ACTIVITY lasted in Nevada from the beginning of the Tertiary period to within a few hundred years ago, but many of the hot springs which accompanied or followed the different manifestations of volcanic activity are now extinct.

KAOLIN OR CHINA CLAY is a decomposition product, particularly from orthoclase feldspar. It is obtained by washing a variety of decomposed, and often disintegrated, granite. In Cornwall, deposits of this mineral have been found to exceed 900 ft. in thickness.

THE apex law has not been repealed. A lode-locator may follow his vein downward outside of and beyond his side-boundaries within his extended end-line planes, provided, of course, the apex is found crossing his lines in such a way as to confer upon the locator that privilege.

MONAZITE is an anhydrous phosphate of the rare earths of the cerium group, but it usually contains also a variable amount of thorium, and it is this element that gives the mineral its commercial value. When separated, the thorium oxide is used to saturate the cotton mantles of incandescent gas burners.

DELICATE speed-regulating apparatus is required when a dynamo is geared direct to a windmill. In a new system, the windmill pumps water into a hydraulic accumulator, and water from this (kept by automatic valves at a pressure of 75 lb. per square inch) drives the dynamo. A storage battery saves the surplus power in the usual way.

THE ozokerite deposits of Utah occur in shales, shaly sandstone, and limestone strata at the north end of the Wasatch plateau. It is a mineral wax; it cuts easily, somewhat like hard cheese, but does not adhere to the knife. It is usually black, with yellow resinous parts. It melts between 54 and 70° C. and is completely soluble in boiling ether.

AT JOACHIMSTHAL, in Bohemia, now celebrated for its uranium ores, the best veins are in a dark, biotitic, feldspathic, rarely garnetiferous, often carbonaceous, schists, rather than in the pale muscovitic or garnetiferous rock. These mica schists are traversed by dikes of porphyritic granite. The uranium ore is mainly pitchblende, occurring in quartz and dolomite.

ASSESSMENT WORK must be done on, or for the benefit of, each claim each year. When several claims are held in common and are contiguous, work may be done on one of them on a main shaft or tunnel, provided that method obviously tends to develop all the claims in the group. As to whether a given method of working will or will not tend to develop all the claims in a group, depends upon local conditions. It is safer to do the work on each claim. Where work is done, however, on one claim for the benefit of several, the aggregate amount must be the equivalent of \$100 for each claim; for example, if the group consists of five claims, \$500 must be expended in improvements.

A GAVE permission to B to place an arastra on his ground and operate it, using water belonging to A. Subsequently B quit operations, leaving the arastra on the ground. A wishes to know if B, by placing the arastra there and using the water, acquired any right to the land or water, or if B can now resume the use of the arastra without A's consent. There was no written lease or understanding as to length of time B was to enjoy the privilege. The transaction amounted simply to a verbal license, revokable at the will of A. B acquired no permanent rights on A's land or in the water. If A notifies B that the privilege is revoked, B's rights cease. He would, however, probably have the right to remove the arastra within a reasonable time after notice.

THE tolerance of heat shown by Europeans in Central Australia appears to give some support to Sambon's theory in regard to acclimatization. Sambon holds that there is nothing to prevent Europeans living and working as well as any black race in the hottest of tropical localities. He maintains that the supposed unsuitability of the tropics for European settlement is due to disease and not to climate, and that as the special tropical diseases are due to germs, they may be cured or prevented when the life histories of the germs become known. As a matter of fact the climate of subtropical Australia, with its exceedingly low humidity (in the interior) and its wide annual range of temperature, is quite unlike that of such regions as West Africa and the Philippines.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Standardization of Screens.

The Editor:

Sir—The principal novelty in the report of the South African committee on the standardization of screens, consists in taking a series of arbitrary size apertures and an irregular number per inch, so that wires of varying diameter and varying number of apertures per inch will (in the 12 examples given under each standard aperture), give with each size wire the particular aperture called for. Secondly, ‘aperture’ is everywhere used for the obnoxious and ambiguous ‘mesh,’ this being in accordance with my article in *The Engineering & Mining Journal*, November 7, 1903.

Lastly, no mention is made of other workers in this field. You yourself have been an early writer on the subject. The Institution of Mining & Metallurgy has done some good work along these lines, although I started in to correct the evil 23 years ago. When I found in Cornwall as many standard gauges as there were battery screens, I took the most rational gauge, which happened to be that of J. & F. Poole, of Hayle; measured it, and published the results in the *Proceedings* of the Mining Institute of Cornwall, 1883, page 344. This Poole standard Cornish gauge for perforated plate was numbered from 1 to 40. No. 1 aperture was 0.25 in. diam.; No. 10, 0.70; No. 20, 0.105; No. 30, 0.055, and No. 40, 0.01 in., the last being the finest perforation then attainable. The wire gauge used in the published tables of the South African committee is the Imperial Standard, and for illustration one cannot do better than re-produce the complete table for 0.030 aperture:

APERTURE 0.030 IN. 0.762 MM.				
Wire.		Apertures per inch.		Per cent discharge area.
Imperial gauge	Diameter in decimals of an inch.	Linear	Square	
21	0.032	16.13	260.11	23.41
22	0.028	17.24	297.22	26.75
23	0.024	18.52	342.92	30.86
24	0.022	19.23	369.83	33.285
25	0.020	20.00	400.00	36.00
26	0.018	20.83	434.02	39.06
27	0.0164	21.55	464.49	41.80
28	0.0148	22.32	498.23	44.84
29	0.0136	22.94	526.06	47.34
30	0.0124	23.59	556.25	50.06
31	0.0116	24.04	577.83	52.01
32	0.0108	24.51	600.74	54.07

No.	Inch.	No.	Inch.	No.	Inch.
1	0.250	15	0.128	28	0.060
2	0.230	16	0.123	29	0.058
3	0.225	17	0.117	30	0.055
4	0.220	18	0.114	31	0.050
5	0.210	19	0.110	32	0.040
6	0.200	20	0.105	33	0.035
7	0.185	21	0.100	34	0.032
8	0.180	22	0.095	35	0.030
9	0.175	23	0.090	36	0.028
10	0.170	24	0.085	37	0.025
11	0.160	25	0.075	38	0.020
12	0.150	26	0.070	39	0.015
13	0.140	27	0.065	40	0.010
14	0.135				

From which it will be seen that 12 wires of different gauge varying from 0.032 in. diam. to 0.0108 in., will each when spaced give from 16.13 to 24.51 apertures per linear inch (depending on the gauge used), and leave apertures of 0.03 inch. It will be further noticed that in the whole table for the 0.03 inch aperture there is but one even division of the inch, namely, No. 25 wire, with 20 apertures per linear inch. The arbitrary division of the inch into an irregular number of apertures, nearly all carrying two places of decimals, does not look practical nor is it necessary. A slight variation in the exact

size of aperture is of no particular moment except in testing screens.

The Washburn & Moen gauge, the American standard, with an even number of apertures to the linear inch, for example, gives the following:

Number of wire	Apertures per inch.	Size of aperture.
21	16	0.0308 in.
23	18	0.0288 "
25	20	0.0266 "
29	22	0.0304 "
33	24	0.0299 "

All of which are sufficiently close for any practical purpose. Great exactness in battery-screen apertures is an unnecessary refinement, inasmuch as screens are subject to continuous wear, thus a standard 0.02-in. aperture screen may become 0.03 in. after a few days' run, and the average aperture for the period may approximate 0.025 in. For what are called laboratory screens, however, the greatest possible exactness attainable should be insisted upon, and all weekly or monthly battery samples should be treated wet in these standard screens and so reported; by this means the exact work of the batteries can be closely approximated and the reduction of the ore determined with scientific precision, not alone for the maximum aperture, but also for the intermediate sizes; thus, a battery crushing approximately through 0.02-in. aperture might be reported

0.02 %	0.0025 %
0.01 "	0.002 "
0.005 "	0.002 "

I have called attention to the use of these standard testing screens, which I invariably use as standards, in my paper on ‘Dry Crushing,’ read before the Institution of Mining and Metallurgy, London.

PHILIP ARGALL.

Denver, November 2.

The Need of Experience.

The Editor:

Sir—There were three mining graduates—one each from three of the best mining schools in the country—who were employed at the B mill in M county, Arizona. One was acting as consulting engineer, and at the time of the incident was the superintendent also. Another was running the mill, and the third the cyanide plant. The millman was off for a few days, and Mr. N., one of the men at the mine, who claimed to be a millman of some experience from Douglas Island, came down to run the mill. He made some changes, some of them for the better; and he talked so well that he got the complete confidence of the superintendent.

At clean-up time the regular millman was back, and Mr. N. remained to help in the clean-up and give what pointers he could. After the plates had been given their regular cleaning, he did not think they were cleaned close enough and stated that he could get 200 oz. more off the plates. The superintendent (and consulting engineer) finally agreed to give him so much per ounce after the first 100 ounces.

He sent for his partner, who was at the mine, and both went to work at the plates with blocks of wood, sand, and quick. They cleaned up the 200 oz. and then some more, and made good wages that day. The amalgam was fine-looking, and the superintendent was jubilant. That night the retorting was done by the cyanide man, and when it was opened, there was scarcely anything left. The cyanide man was accused of heating it too hot, and boiling it over with the quick. The quick was then squeezed, but there was nothing there. Next morning the consulting engineer and millman retorted some more of it with the same result. It was then tested and found to be mostly copper. It is needless to say that the plates

were pretty well scoured to the bare copper and in pretty bad condition.

Of the three mining graduates, not one of them knew enough about the care of plates to know that anything was wrong until it was too late. It simply shows the need of experience for the mining graduate as much as the non-graduate.

E. D. C.

Terry, S. D., November 11.

[The young men mentioned must have been unintelligent. Any course of lectures on the metallurgy of gold would include a description of amalgamating plates and the care of them. Graduates or non-graduates who go into a stamp-mill without reading the books available on that subject are just plain chumps.—EDITOR.]

Debris Dams for Conserving the Water Supply.

The Editor:

Sir—In taking a trip up one of the narrow southern California cañons one cannot but observe the enormous erosion that is taking place during the rainy seasons, and especially after the frequent summer rains that often assume the dimensions of a waterspout. Perhaps the latter have a more scouring or eroding effect than the winter rains on account of the lack of protection that is naturally given by the immense snowfields, and the fact that the winter rains, while the aggregate volume is great, the precipitation is so gentle that comparatively there is little erosion in the higher altitudes.

Before the wholesale destruction of the timber in the mountains, this erosion did not take place to any such great extent, though of course even then immense quantities of debris swept out of the mountains after every heavy rainfall.

There is no need in this letter to bring out the usual points in favor of the preservation of our forest area, except to call attention to the great importance that accumulations of debris had in the matter of conserving the water supply by the storage furnished by immense gravel beds that allowed the water to percolate out gradually, averaging the flow and to a certain extent lessening the destructiveness of the annual floods that sweep down the mountain streams. This was naturally brought about by the accumulations of fallen timber, roots, etc., which in their turn held boulders, gravel, sand, and silt, checking the top flow by the area of the underflow and thus again aiding in the accumulation of debris until a mean was reached proportionate to the heaviness of the timber growth. The writer is of the opinion that this natural result from a heavy growth of timber has a greater effect in conserving and regulating the water flow than any other feature to be considered in favor of forest growth as of paramount importance to the irrigationist.

Many causes aided nature in the accumulation of debris, fallen trees, limbs, etc.; snowslides, windstorms, and landslides all added to the accumulations in the narrow cañons of our lofty mountains. Nor can it be said that this effect was merely local, as would be the case were the debris held back as water is behind a dam; rather, the debris would assume practically the grade of the cañon, except where the fall was precipitous. This will explain the anomaly why heavy growths of brush on the mountain-sides do not conserve the water in anything like a proportionate ratio to a growth of heavy timber, although undergrowth possibly furnishes a better protection to the soil underneath than a heavier growth of trees.

The flow of water through gravel beds is known to be very slow. In some places, as in the San Fernando cañon, near Los Angeles, tests show the travel to be no more than a mile per year, thus providing a flow that is

scarcely affected by years of drought, at the same time reducing the amount in seasons of flood by taking the excess and holding it in suspension in the beds of gravel. The importance of these immense deposits of gravel, in favorable situations, is well known in the irrigation problem; the only point we wish to consider is the practicability of adding to and conserving our water supply by means that are within our reach, the expense of which would not be prohibitive.

This brings us to the debris dam. By this I mean the dam that is commonly used by the hydraulic miner in the northern parts of the State for the purpose of impounding the debris with the object of preventing the filling up of navigable streams and the causing of overflows by the blocking of the channel. It is claimed by some that they have but a minimum effect in this regard, but even this does not lessen their importance as a means of providing an artificial substitute for previous natural conditions in restraining debris and insuring a better and more regular water supply. It is generally conceded that our present water supply is only going from bad to worse, and that the scouring that is taking place will ultimately result in its being limited to the melting snows and the storage capacity of our reservoirs. Hence the importance of this subject.

The ordinary debris dam, of which numerous illustrations have from time to time been published in the MINING AND SCIENTIFIC PRESS, is possible of being constructed cheaply, yet owing to the interlocking nature of the filling that takes place behind, it becomes practically indestructible, and can be added to as the conditions require. It is usually built of logs or poles, the small end of the tree being placed up-stream so as to be first buried in debris, thus locking it in position. These are usually nested in the cañon, all lying one way, no means being taken to tie them together, and usually with a slight slope on the lower end to break the overflow and prevent cutting by the waterfall. Where timber is scarce these could be built in a modified crib shape, yet it would be necessary to have a sufficient number of trees of full length extending up-stream to insure holding. Not having the advantage of a hydraulic stream, it would be necessary to use a layer of heavy boulders to hold these until the natural flow of debris had filled in behind and over them.

Favorable sites could be selected for such debris dams. Nor is it essential to secure great height; rather, it would be more practicable and cheaper to make as large a number of these dams as the conditions justify, of a moderate height, with the intention of adding to them or interspersing more dams between them from year to year.

Where a road runs up these cañons it would be necessary to build a new one over or around the dam, changing the road from time to time as the conditions demanded, with possibly less annual expense than where the cañon is allowed to cut out at will.

Power companies would certainly co-operate in a matter so vitally affecting their interests and in most cases could be expected to take the initiative.

This field offers a possible practical solution of the question of conserving our water supply for the future; or if carried out in a thorough manner to go even further and increase the water supply in years of drought, speaking conservatively, 25, 50, or 100 per cent.

A. E. CHAPMAN.

Redlands, Cal., October 31.

MEXICO is trying to solve the labor problem by importing Japanese. About 1,000 have been brought in, and 2,000 more are to come. Most of those who have been in the country some time marry Mexican women.

Devices for Shaft-Sinking.

Written for the MINING AND SCIENTIFIC PRESS
By DONALD F. CAMPBELL.

A convenient arrangement of doors to protect the top of a shaft in sinking is shown in the accompanying illustrations (Fig. 1, 2 and 3). By this simple system of levers and counter-balances, one man can easily raise both doors simultaneously, and lower them immediately the bucket reaches the surface. The car is then run over the doors, and the bucket emptied. By this means extraction of

Fig. 1.

waste is facilitated and the safety of the miners increased.

In the case of deep shafts, a great deal of time is unnecessarily wasted owing to the slow speed of winding. A big saving can be made by the use of a system of guides (Fig. 4). Wire ropes are made to pass over two pulleys at the top of the shaft, parallel to the winding

ceive the guides. This rider descends with the bucket to the stage, which is usually ten yards from the bottom, and below this it continues unguided. As the bucket is again wound up, the rider is caught up again on a collar at the bottom of the rope, to which a rubber buffer is attached to reduce the shock.

GOLD DEPOSITS OF THE SOUTH.—One great cause of the lack of success which has attended gold mining in the Southern Appalachians lies in the fact that instead of one recognized and well-defined type of gold deposit, as is the case in most mining districts, there are various types exhibiting a very wide range in character, and individual mines present more and greater differences than sim-

Fig. 4.

ilarities. Such conditions, whether they are appreciated or not, mean expensive mining. Advantage can be taken of past experience to reduce the cost of exploitation. If methods which have proved successful in one mine are employed in another the chance is that they will be unsuccessful because they are not adapted to the dissimilar

Fig. 2.

pulley, and are attached to a platform, which serves as a timbering stage and is raised or lowered as required. The guiding apparatus consists of a cross-bar having a round hole in the centre, through which the rope passes. It has two legs with holes at the top and bottom to re-

Fig. 3.

conditions of the second mine. Accordingly the owner is loath to apply to a new mine methods which have proved successful elsewhere, and is inclined instead to try new methods which may miss the mark as widely as those already in use.—L. C. Graton, U. S. Geol. Survey.

A Simple Solution Meter.

Written for the MINING AND SCIENTIFIC PRESS
By E. H. NUTTER.

In the operation of cyanide plants, it is nearly always important to have a means of correctly determining the amount of gold-bearing solution entering the precipitating boxes. In some plants this is done by alternately filling and discharging sump-vats of fairly good size, and recording the height of solution each time a sump is filled. This is a clumsy, though accurate enough, method, but has the objection that it requires nearly constant attendance. Various water meters are manufactured which can be used for solution work, except that those of sufficient capacity are expensive, and are open to the objection that the lime which is used in practically all cyanide-plant solutions, soon deposits a scale in the working parts of the meters, which renders them inaccurate or puts them out of business altogether.

To meet these objections I adapted the familiar sampl-

Fig. 1.

ing box illustrated herewith, to the requirements of the case, and one was installed as a meter at the Liberty Bell mill. The device is simple and cheap, and as others may find it useful, a description of it is not out of place.

The arrangement can be seen by reference to Fig. 1. (Fig. 2 is a view of the meter as installed.) The compartments *B B'* alternately take the solution flow from the feed-pipe. As a compartment fills, the weight of solution overbalances the empty compartment and the box turns through a short arc, discharging as it turns, until it is stopped by the springs *SS'*. Each time *B'* discharges the counter registers. The meter at the Liberty Bell is set up over a vat, and the pans shown in the diagram are always submerged. Their retarding effect is necessary to avoid excessive jar. A dash-pot would probably do as well, or else the box could be made of metal with a pear-shaped cross-section, and hung close up to its centre of gravity. The latter form would not need the springs or pans.

At the Liberty Bell, the constant of the meter was determined by filling the vat under it and dividing by the number of double discharges registered. In this way leakage, splash, and all other irregular factors are averaged, and determined. The constant so determined was

0.32275 tons for each unit registered. This meter handles the flow from an 80-stamp mill crushing in cyanide solution. For this size of meter the pans should be at least 36 in. diam., and the springs made of not less than $\frac{1}{4}$ -in. rod. A four-inch hole in the bottom of each pan tends to steady its motion through the solution.

DISTRIBUTION OF GOLD.—At the Haile mine in South Carolina the ore values are distributed as follows: The uppermost portion of the deposits, which was worked as placer ground, was rich. Below this surface mantle the values have decreased, as far as known, rather steadily, although pockets of sulphide ore of better than average grade have been encountered, probably most commonly near the boundary of general decomposition. The limit to which economic mining can be carried appears to bear a pretty definite relation to distance from the surface, and that distance is not great and reaches not very far—usually less than 200 ft.—below the limit of complete oxidation. Moreover, thin films and scales of pyrite and of free gold have been found in joint cracks which give every appearance of having been formed since the silicification of the rock and the attendant ore deposition.

Fig. 2. A Solution Meter.

Thin films of free gold are commonly found on molybdenite associated with heavy pyrite bands. Finally, it is certain that the comparatively plentiful gold which was found at the surface of these deposits and which was derived from higher portions of the deposits now eroded away has remained in that place undisturbed for a long period—in fact, ever since the peneplanation of the region, which probably took place as early as Tertiary time. Erosion at these places has been almost at a standstill and the process of secondary enrichment of the deposits, slow as it is, has had time to be effective. The writer does not undertake to say that secondary enrichment has had much to do with the vertical distribution of the gold, but it certainly seems possible that it has. If such a process has gone on, the action has differed from that common in copper deposits, inasmuch as the copper is derived largely from the upper portion of the deposit *in situ*, while the gold is supposed to have been dissolved mainly from gold which rested upon what was then the surface of the deposits and which had been previously concentrated by mechanical means virtually as placers. L. C. Graton, U. S. Geological Survey.

THERE appears to be some natural law governing the proportions of uranium and radium in rock samples, inasmuch as when the percentage of uranium is known, the amount of radium can be predicted with certainty.

Zinc Resources of British Columbia.

A comprehensive report by the Commission appointed to investigate the zinc resources of British Columbia and the conditions affecting their exploitation has just been issued by the Mines Branch of the Canadian Department of the Interior. The Commission, which was appointed as a result of petitions from the Silver-Lead Association and Associated Boards of Trade of British Columbia, consisted of Walter R. Ingalls, editor of *The Engineering & Mining Journal*, New York, as chief, with Philip Argall, of Denver, Colo., and A. C. Gardé, of Nelson, B. C., as his associates. They had the assistance of A. E. Barlow and Joseph Keele, of the Dominion Geological Survey, who were detailed to investigate the undeveloped zinc ore deposits. The result of their labor is a volume of 399 pages, giving full details concerning the zinc mines and deposits of British Columbia and the processes of production, in addition to much general information concerning the zinc industry and others with which it is associated. The volume contains a large number of excellent maps and illustrations.

The beginning of the zinc industry of British Columbia was practically contemporaneous with its origin in Colorado, the first shipments having been made in 1899. These were chiefly from the Lucky Jim mine near Sandon. A period of inactivity followed, but in 1902 the Lanyon Zinc Co. of Iola, Kansas, began purchasing freely, and other smelters shortly afterward furnished a market. Mr. Ingalls estimates the shipments for the last three years as follows: 1903, 2,567 tons; 1904, 2,828 tons; 1905, 8,561 tons. According to W. F. Robertson, Provincial Mineralogist, the production of zinc ore in 1905 was 11,623 tons. The report of the Commission says that the actual production for that year was possibly 3,000 to 4,000 tons more than the shipments, but this is largely ore held for treatment by magnetic separation, so as to enrich the grade in zinc, which will correspondingly reduce the weight.

The zinc ore hitherto produced in British Columbia has been marketed chiefly in the United States, the smelters at Pueblo, Colorado, and at several points in Kansas, having been the principal buyers. A comparatively small quantity has been exported to Europe. Since the end of November, 1905, a smelter at Frank in Alberta has been in the market. All the ore sent out of the Province in 1905 went to the United States. The ore produced has been blende. No calamine has been shipped and the existence of any important supply of this class of ore has not been reported. The blende has been shipped partly as hand-sorted lump ore comprising the higher grade in zinc, and partly as mill-concentrate. The grade of the latter is reduced by the intermixture of siderite (spathic iron ore) and pyrites (pyrite and pyrrhotite), which occur commonly with the blende of the Slocan and cannot be satisfactorily separated by ordinary mechanical concentration. The blende of the Slocan is 'black jack' and generally of bright lustre, but it is not high in iron.

There are some mines in the West Kootenay that are essentially zinc mines, the best examples being the Lucky Jim and Blue Bell. In each case these were worked originally as silver-lead mines with results that were not encouraging. The proportion of galena to the remainder of the ore was small and it was poor in silver. The Lucky Jim has recently produced upward of 5,000 tons of zinc-blende, assaying 50% or more in zinc, broken to a considerable extent from solid bodies of the mineral and shipped in lump form without cutting. The Blue Bell also shows rich faces of blende ore, which, although mostly of a concentrating grade, will afford a large pro-

portion that selected by hand-sorting is of comparatively high grade. The majority of the West Kootenay mines, however, are essentially silver-lead mines in which zinc-blende occurs as a by-product. In this respect they are similar to many other mines in the Rocky Mountains in which zinc-blende occurs in association with galena, pyrite, and other argentiferous and auriferous minerals. The increased demand for zinc ore during the last few years, which is likely to continue, has made zinc a valuable by-product. While comparatively few of the Slocan mines can be worked profitably as zinc mines, there are many that are worked for silver-lead ore, such as the Slocan Star, in which the zinc ore will be an important item. The yield of silver-lead ore will always be the dominating factor in the operation of these mines.

The method of developing the mines of the Slocan has been such that at the present time there is comparatively little ore that can be estimated as blocked out. The lack of development, and the irregularity of the orebodies, render it difficult to formulate any reliable estimate of their zinc-producing capacity. A calculation based on the production of lead ore in the Slocan during the nine years from 1895 to 1903, indicates the possible production of 30,000 tons of blende per annum provided all the zinkiferous ore were concentrated. This is obviously an improbable result and all things considered, Mr. Ingalls regards 15,000 tons of zinc ore of 50% grade as a liberal estimate for the productive capacity of the Slocan. Mr. Argall considers that the mines of Ainsworth camp can, from present developments, produce about 54 tons daily of zinc ore of 50% grade and might be able to attain an output of 100 tons daily of 45 to 50% stuff in a year or two, if the deposits were mined and milled on a scale commensurate with their magnitude. This estimate is liberal. The conclusion is that the tonnage of ore to be expected is too small to warrant the erection of independent zinc-enrichment plants at the several mines.

The possibility of enriching the zinc ores by magnetic separation, says the report, has been thoroughly demonstrated by the tests conducted by the Commission. The ore tested was of wide variety, representing all the classes now produced in the British Columbia mines. In every case it had been possible to produce a zinc concentrate assaying upward of 40% zinc, in many cases a concentrate assaying about 50% zinc and in a few cases as high as 57% zinc.

These results compare favorably with those attained by the concentration of similar ores in the United States, Australia, and Europe. It must be remembered, however, that a good technical result is not necessarily a good commercial result, owing to the remoteness of the Province and the long railway carriage to markets. Ore assaying only 40% zinc, unless it also contains important silver value, will not be a profitable product in British Columbia on the basis of 5c. spelter. With the exception of a few specially difficult ores, the tests made by the Commission showed remarkably high percentages of extraction, rising in one case to nearly 99% and being upward of 90% in many cases.

The productive districts are fairly well served with transport facilities by existing railway lines. The Canadian Pacific and Great Northern railroads combined with the splendid system of water transportation provided in the Arrow, Slocan, and Kootenay lakes afford good communication through all the districts. The most serious feature is the cost of carriage from the mine to railway or lake, because of the position of many mines on steep mountain sides, in many cases remote. This condition is a bar to the working of many properties.

The Development of the Metal Mining Industry in the Western States.

By WALDEMAR LINDGREN.

*The development of metal mining in the Western States is really a story of the gold and silver mining of the United States, worthy of the genius of a historian; it is a magnificent drama of human endeavor, full of romance and tragedy, of pathos, and even of humor; a story of the valiant struggle of a race of pioneers to conquer the wilderness. And this drama has been enacted in a worthy and ever changing setting; from the vine-clad foothills of the Sierras it reaches to the sagebrush plains of Nevada and to the crests of the Rockies; from the tundras of Cape Nome it extends to the forests of the Cœur d'Alene and to Arizona deserts, where the mirage plays with purple mountain ranges.

The most wonderful feature of this drama is that the main part of it has been enacted within the memory and experience of men now living—within the short space of fifty-eight years. There was a prelude to it, however; where the northernmost waves of Spanish civilization broke against the ranges of New Mexico, dim records exist of gold, silver, and copper mining as far back as the seventeenth century. And much more recently—in 1828, and following years—gold was washed by New Mexican placer miners in the Ortiz and San Pedro mountains almost simultaneously with the beginning of the gold mining industry of Georgia and the Carolinas.

Western metal mining began with the application of the easiest of metallurgical processes, that of washing gold from gravel. This first epoch—that of placer mining—was initiated when Marshall discovered the yellow nuggets in his millrace at Coloma, Eldorado county, California, early in 1848. The first decade was pretty fully occupied by gulch and river mining. In the second decade two important methods of mining were developed. By hydraulic mining, carried on in California on a scale never equaled elsewhere, whole mountains were washed away while gold to the amount of a few cents per cubic yard was saved at a profit. By drift mining, the gold stored in the bedrock channels of the old Tertiary rivers was extracted by means of long tunnels in the gravel under a lava cap. Both methods are of course still practised and, transplanted by California miners, they flourish in other States, but their glory began to wane toward the end of the seventies.

Up to 1859 the gold production had been chiefly confined to California, but the following decade witnessed the first attack on the wilderness between California and Oregon. Brave bands of prospectors opened a score of new goldfields. This was the time of Auburn and Canyon City in Oregon; Florence, Elk City, Warren, Oro Fino, and the Boise Basin in Idaho; Alder Gulch, Confederate Gulch, and Last Chance in Montana; Clear Creek and California Gulch in Colorado. All of these placer camps flourished in the early sixties, but excepting the Boise Basin, most of them were shortlived, and were eventually turned over to the patient Chinamen.

The waning of placer mining was marked by a decrease of gold production from \$60,000,000 in the early fifties to a minimum of \$30,000,000 about 1883. Of a second epoch of placer mining I shall speak later.

The working of gold-quartz followed closely on the heels of placer mining, but here arose an entirely different and much more complicated problem, which first the talent of the Southern Appalachians, then that of Europe, was called upon to solve. Mistakes were many and grievous; the ores below the water-level proved a special stumbling block, and it was not until from 1870 to 1880

that the industry was placed upon a firm footing. In California this was accomplished by breaking from European practice and the invention of the heavy iron-stemmed stamp, the broad amalgamation table and the vanner, and lastly by the application of Plattner's chlorination process to the product of the concentrator. In Gilpin county, Colorado, slightly different processes were adopted. Few of the early placer districts proved rich in gold-quartz veins; this industry, though important, failed to prevent the gradual decline of the gold production. But men were now available who understood the simpler problems of mining and milling.

The exploration of the wilderness in the sixties was rewarded by the discovery of thousands of deposits, from Montana to Arizona. But most of them were not of the familiar type of gold-quartz veins. They contained strange minerals, black or brown masses that turned to silver in the forge, glittering galena, golden chalcopryrite, and deceptive blackjack—some of them unknown and most of them worthless to the pioneer far from lines of communication. The silver ores seemed most promising; to these the miner turned his attention, and so began the third great epoch—that of silver mining.

This new industry was born in Nevada about 1860, though it did not reach its maximum until many years later. Tuscarora, Austin, Bodie, and, greatest of all, Virginia City, what memories do not these names bring back to the old miner? To the north, in Idaho, flourished the Owyhee mines, the Custer and the Atlanta districts; to the south many a camp in the Mohave desert and in Arizona. Confronted by new conditions, the engineer was forced to develop new processes. It is impossible to over-estimate the importance of the Comstock as a school for mining—really the first characteristically American school in the West. Timbering by square sets, to remove large and rich orebodies, modern hoisting and pumping engines, deep sinking, the fight against the subterranean heat, all these made the Comstock a Mecca for mining men thirsting for knowledge. Another important step forward taken about this time was the substitution of dynamite for the ordinary black powder, and power-machines for hand-drilling. The pan amalgamation process—with or without roasting—and the roasting and leaching process, if not new in principle, were developed to suit local conditions.

From the palmy days of Nevada in the seventies, silver milling steadily declined until at the present time one rarely hears the dull roar of the millers in the iron pans. But in spite of the enormous production of the Comstock, it was not the silver milling of dry ores that glutted the market; it was the stream of the white metal pouring from the smelting works. In historic Gilpin county the smelting industry started in 1868, modestly enough in its beginning, and giving little evidence of the gigantic proportions it was to assume some thirty years later. It was found that the despised sulphide ores contained copper and lead which could be made useful in collecting the silver and the gold, not only in these, but in rebellious dry ores. Our teachers in copper smelting were Welshmen and Cornishmen, while Germans instructed us in the reduction of the lead ores. In the seventies several smelters were operating in Colorado, and the silver-lead mines at Eureka, Nevada, were producing richly. Soon Montana and Arizona established smelters, and from that time to the present day the history of smelting is one of almost continuous progress, during which our European teachers eventually were left behind.

About 1875 the Leadville smelting ores were discovered above the placers of California Gulch and the silver production of Colorado doubled in a year. Aspen soon

*A paper read before the American Mining Congress, at Denver.

added its masses of argentiferous lead. Idaho contributed heavily from the rich smelting ore of the Wood River district. Treasure poured in from Park City, Utah. Steadily the silver output rose and equally steadily the price sank. The maximum of production of 63,600,000 oz. was attained in 1892; since then the annual yield has averaged 55,000,000 oz., but the decline in price was not checked until ten years later, when the record read 47 cents. Nearly one-half of our present output is a by-product obtained from smelting of low-grade copper and lead ores.

The last chapter of the remarkable story of silver is familiar to us. Rapidly rising, the price has attained 70 cents, a fact which may seem surprising, but indeed is really only the logical outcome of lately prevailing conditions. The mines will respond to the demand—their ability to do so is scarcely to be doubted—and we may stand at the beginning of a second epoch of silver mining.

Let us now, just for comparison, glance back at the condition of the western country about 1883; California, yielding a decreasing amount of gold, was still the proud leader. Nevada's smelters and mills were decaying. Arizona produced a fair amount of silver from the Tombstone, Silver King, and other districts, the copper industry was in its veriest infancy at Globe, Clifton, and Bisbee, while United Verde was unknown. Colorado was going strong in silver and lead. True, its gold production was small, but it was bravely held by old Gilpin county. Cripple Creek was a cattle pasture. In the San Juan country, only discovered a decade earlier, some silver was laboriously and expensively produced, with gold as a by-product. Utah had its Park City, Horn Silver mine, and Tintic, but who dreamed of a great copper industry to rise in the dull camp of Bingham? The Mercur ores lay unheeded underneath their blanket of limestone. In Montana, much silver mining was going on. The lead smelters were active and some silver-gold mills were in operation. The first Anaconda smelter, with its wasteful concentration and its rows of Welch reverberatories, was planned; the possibility of Butte turning into an important copper camp was seriously discussed. In Idaho, prospectors were just trenching the Cœur d'Alene outcrops after the wild mid-winter rush to the Murray goldfield. As to Alaska, that Territory slumbered through Arctic storms and midnight sunshine; nobody suspected what would happen on Douglas island, at Cape Nome, or on the Tanana, twenty years later.

The world woke up one morning in the early eighties and found itself decidedly short of gold; as many know, this is a disagreeable feeling. The United States had barely produced thirty million dollars in the last year. The search for gold proved easier than expected. In the last decade of the past century the production rose rapidly; from 1893 to 1900 it more than doubled.

This condition of affairs was partly due to the engineers, but largely to the prospectors. The early nineties saw some wonderful technical improvements. First among them is the cyanide process, the practical application of an old, half-forgotten fact that gold is soluble in cyanide of potassium. Its importance cannot be overstated. Developing rapidly, it is today an art in itself, providing a cheap method for the reduction of many precious-metal ores formerly only partially tractable to pan amalgamation. But most important of all, it provided ready means of extracting the gold from the tailing of the amalgamation and concentrating mills, intractable masses which had piled up in reproachful heaps or guiltily escaped down stream. The perfection of the barrel-chlorination process also belongs to this epoch.

About this time electricity came upon the scene. Pumps and hoists and mills could now be driven at reasonable cost from distant waterfalls or coalfields. Mining methods improved and new ways of extracting great orebodies—such as the filling and caving systems—often replaced the expensive square sets. The invention of the small drills for stoping was another step forward. When steam was used, compound engines replaced wasteful single cylinders. The catalogue of improvements could be easily extended. As a consequence, hundreds of deposits abandoned by the early miners at water-level were re-opened and made productive.

But all this technical progress would not have doubled the production. The second factor was the prospector, who succeeded in demonstrating the fallacy of the belief that all the gold deposits of this country were known. In Cripple Creek, at Creede, in the Black Hills, and in the many recently discovered rich districts of Nevada, we see the results of his work.

The third factor is what may be called the revival of placer mining. Since 1897 the old scenes of 1849 have been re-enacted with modern modifications in Alaska, raising the placer production of the Territory to about \$12,000,000 in 1905. New conditions led to new inventions—among them the mining of frozen ground by steam. Nor can it be said with assurance that the epoch of discovery in Alaska is past; that frosty Territory may have further surprises in store for us. Meanwhile the gold dredge began to add to the production of the old diggings in California and elsewhere. In 1904, California produced \$2,000,000 from this source. Nevertheless, the dredge and the dredging deposits have their limitations, and the yield from this source is not beyond calculation.

From 1900 to 1904 gold production remained stationary, except for a decided decline in 1903. But 1905 saw a sharp increase to about eighty-seven million dollars, and it is more than probable that the present year will surpass this record. Will the gold production reach the hundred million mark? Who can say it will not, while the pioneers are still exploring Alaska and while the gold camps are multiplying in Nevada? But one fact that should be borne in mind by the enthusiasts who predict a flood of gold is that the heavy increases do not, as a rule, come from the old camps, but from the new discoveries. New orebodies will always be opened, but new camps will not always be discovered at the recent rate.

The interests of good mining are not always served by the finding of rich ore. True progress in the art is more apt to be recorded at the low-grade mines, especially those containing copper and lead, where small economies may make the difference between profit and loss, and so it comes that the best practice and the most modern inventions may be found at our base-metal mines.

Previous to 1880 the West yielded less than a fifth of our total copper production—small as it was—and that fifth was really only smelted for its property of collecting gold and silver. The copper production of the Western States had grown from 5,000 tons in 1880 to about 300,000 tons in 1906, and it has doubled since 1893. A flood of copper is coming from Arizona and Montana, and in its production all the resources of modern mining and smelting are employed. Compare, if you will, the concentration mills and giant blast-furnaces, the converting plants, the electrolytic refineries, in short, the industry based on a 2 or 3% ore with the laborious roasting, smelting, re-smelting, and refining of the 15% ore of twenty years ago. The leaching of copper ores, of which much was expected, remains a subordinate process. The world's appetite for copper is growing at a rate difficult for the

producer to follow. In spite of the incentive of sensational increases in price, the present outlook is not favorable for an increase of production at the rate of the last ten years. The copper industry still maintains a healthy independence, the output being scattered among a large number of producers. The western industry centres in Arizona and Montana, but Utah, Alaska, and California may soon become their rivals.

The lead industry, whose Western centres are situated in Colorado, Utah, and Idaho, has progressed in a similar way. In 1880 only about 80,000 tons of lead was contributed by the West; in 1904 the amount had grown to 220,000 tons, but the production has failed to advance at the same rate as the copper output.

Less conspicuous are also the improvements in mining and smelting. It may be doubted whether the lead resources of the Western States are equal to keep the task of maintaining the present rate of increase, although the price of lead has recently left its time-honored position at four cents per pound and moved up near six. The most notable event in this industry is its recent consolidation into the hands of one strong corporation, which practically controls the output and the price.

The year 1903 witnessed the beginning of the zinc mining industry in the Cordilleran States, and in three years the once anathemized zinc ores were turned into an unexpected source of revenue. It is not difficult to predict a wonderful future for this industry, the technique of which is yet in its infancy. Chief among the problems is the separation of zinc-blende from pyrite and chalcopyrite; this will perhaps be effected by the new electro-magnetic and electro-static machines. Another problem is the utilization of the precious metals contained in the zinc ores. At present they are often wasted. Colorado is the largest producer of zinc ores, chiefly from Leadville, but also from Aspen, Creede, and Clear Creek. The output from New Mexico and Utah is also increasing rapidly.

A monopoly in mining is fortunately a condition that seems very far from us. But there exists unquestionably a tendency in the smelting and reduction industries toward concentration in a few hands. Doubtless this is attended by some advantage. the miner in the way of a ready market for his ore, and often also in a diminution of reduction costs due to operation on a large scale, but this dependence upon large concerns also carries with it certain disadvantages. One point relating to the marketing of ores may be emphasized. The miner of complex ores is apt to sell his ore—containing copper, lead, silver, or gold—like so much coal at so much per ton as per smelting schedule, and at the end of the year he is totally in the dark as to how much of each metal his ore contained, how much he got paid for, what he failed to obtain pay for, what he could have saved by changing his mining practices in certain ways. This unfortunate habit prevails in a most astonishing degree today in Colorado, and that not only among the small producers, but among many large companies.

We would be ungrateful not to recognize our debt to Europe, Germany, and England above others, for guiding the first steps of our metal industry. We owe much to them, even if their advice, because of a radically differing situation, sometimes resulted in failure. But we should recognize with pride that in the face of many discouragements we have worked out our problems in an independent spirit and always with consideration of actual conditions rather than of authority and pattern. It is this quality, as well as their enterprise and energy, that has placed American mining engineers at the head of their profession. It should be emphasized that it is largely the American mining schools in their

rapid development of the last twenty years that have supplied the material for the profession. Young men now come out of these schools with an adequate foundation of elementary knowledge upon which practice can rear a safe structure.

To look backward upon the magnificent achievements of the past is useful only as an incentive for further steps in advance. That such steps are being taken every day of the year in every State of the West is a fact with which all of us are familiar. In Colorado, Utah, Montana, Nevada, and California, mining is at a high tide, and the best promise lies in the fact that so many new mines and districts are coming to the front. We know that the West can produce more silver, perhaps it can produce more gold, possibly more copper and lead. But shall we be able to maintain the terrific pace set? And to this the Western Spirit, in calm confidence, answers that it can try. It has already accomplished things once thought impossible.

IDENTIFICATION OF STREAM TIN.—Let us suppose the prospector in the act of panning off a dish of gravel. He has thrown out the larger pebbles, and the material remaining in the pan is clean washed gravel. Perhaps as his washing continues, and he rids the pan of the bulk of the lighter sand, he may find in the diminishing residue a number of pretty stones, crystals of different colors and of varying transparency. These may be crystals of topaz, garnet, zircon, tourmaline, or sapphire, and if the prospector has any skill in applying the test for hardness he will be able to identify these crystals fairly well. If he is a judge of their other properties, so much the better; he can then make confirmatory tests. The sapphire will scratch a topaz, and they will both scratch a quartz crystal—the sapphire, quite easily, and the topaz less so. The other crystals will also scratch quartz if a sharp edge or point is used with a fairly heavy pressure. The presence in the pan of the above minerals is a good indication of the possible presence of stream tin. As the panning off continues, black sand will perhaps begin to appear. This black sand may consist of magnetite, ilmenite, wolframite, tourmaline, or of stream tin alone, or associated with any or all of these minerals, some of them perhaps in the state of fine sand, and some in pieces large enough to be easily picked out with the fingers. When the operator has reduced the material in his pan to a good concentrate clear of the lighter sand, the pan should be held over a fire and the contents dried. Then if a magnet will not attract any of the particles, he knows there is no magnetic iron present. If the larger pieces which may remain in the pan show no disposition to be easily separated from the fine they should be picked out and laid aside until some way can be found of testing them. If they are not attracted by the magnet, they are likely to be either tin or wolframite, but the latter mineral may easily be scratched by a quartz crystal. Stream tin varies in size. It may be found from the state of fine sand up to pieces of several pounds weight. It also occurs in many colors, the more common being black, brown, red, and yellow. A sapphire will easily scratch the smooth surface of a pebble or crystal of tin oxide, but a quartz crystal will only make a scratch when a heavy pressure is applied. Tin ore may, owing to its heaviness, be easily separated by panning from almost any other mineral. Where stream tin occurs it may be panned off in quantities varying from a few grains to as high as several pounds weight to the pan, according to the richness of the gravel. With a good body of tin-bearing gravel and facilities for economic working an average prospect of an ounce or less to the pan would give large profits.—Charles F. Walker.

Two Interesting Reports.

The Oriental Consolidated Mining Company, working in the Wunsan district of Korea, issues its reports for the year ending June 30, 1906. The operating profit was \$367,882, and after putting back \$140,637 into new construction, development, etc., there remains a net profit of \$227,245. The after-effects of the Russo-Japanese war hindered production, so that 21,230 tons less were milled than in the previous year. The total output was 236,417 tons, containing \$1,197,637, or at the rate of \$5.065 per ton. To mine this ore it cost \$1.14 per ton, inclusive of all underground development. In the mills the total extraction averaged \$3.89 per ton, a net saving of 76.8%. Of this, \$2.30 was secured as bullion and \$1.59 from the concentrate.

The cost of milling was 62½ cents per ton. Cordwood accounts for 6½ cents. For an average of 266 days, 220 stamps were in operation, crushing 236,417 tons or 4 tons per stamp per day; 19,363 tons of concentrate were separated. The tailing averaged 79½c. per ton. An experimental plant for re-grinding the coarse concentrate was built. This was described in our issue of September 22. The two cyanide plants treated 31,611 tons with an average

the inadequacy of the working capital. It appears that the promoters were in a dilemma; in order to make a successful flotation, it was necessary to maintain a certain parity between the net value of the ore and the total capitalization; to increase the working capital would have destroyed this uncertain equilibrium, therefore the company started with a fund of \$145,000, which proved totally insufficient. The mine is in the Sierra Madre mountains of western Chihuahua, Mexico. It is difficult of access, being a hundred miles from the nearest railroad. Communication and transport are effected over a rough mule-trail. All supplies and machinery must be broken in packages of from 150 to 300 lb. each. During the construction of the mill \$25 was paid for packing a cam-shaft weighing 485 lb., while \$37.50 was paid on a piece of a Cameron pump weighing 630 lb. Owing to the scarcity of mules and the needs of neighboring mine operators, the rates of transport have since been advanced 25 to 30 per cent. The average time for a mule-train to the mine is 10 to 12 days, the journey back without a load requiring 5 to 6 days; the animals need an interval of rest, bad weather makes travel slow, and often stops it for weeks. These facts are worthy of emphasis in connection with the time and money required to equip the mine and put it on a productive basis.

Soon after the property was taken over it was found that the streams near the mill could not furnish enough water during the dry season, therefore a water-right was secured three miles distant and a pump was erected. Mr. Farish speaks of this piece of engineering with proper pride: "This pump is the finest piece of sectionalized machinery of the sort that I have ever seen. It has a capacity of 100,000 gal. daily, pumping through 6,000 ft. of pipe against a head of 1,450 ft. Such conditions impose a severe test on the pumping plant, but this has been met by a Riedler pumping-engine. The plunger of this pump is differential, having 2¾-in. and 3¼-in. bore with 28-in. stroke, actuated by a

Cornbliss condensing-engine. The ease with which it works and the fact that it is a sectionalized machine, surprises all who see it. The tank into which the water is thrown by the pump through 3,000 ft. of 3 in. and 3,000 ft. of 3½-in. pipe, is of solid masonry. From this intermediate tank it flows by gravity through 10,000 ft. of 4-in. pipe to a second tank, also of solid masonry, located on a hill above the mill, and having a capacity of 200,000 gal. The building of these tanks in a country where there is practically no lime was an expensive item."

The report proceeds to give valuable information concerning timber and fuel, mules and pasture, and labor conditions. In regard to the last, it appears that Col. W. C. Greene tried to secure laborers and to do so he increased wages 25%, disturbing the operating costs of all his neighbors—as neighbors go in the Sierra Madre, where the matter of a few miles does not count.

The mill is illustrated herewith. It does credit to Mr. J. Gordon Hardy, the late manager. Rock-breakers deliver to three batteries of five stamps each that crush 60 tons per day through a four-mesh screen. They deliver to three Bryan mills for preliminary re-grinding. Then comes a Gates tube-mill, which slimes the ore to 200-mesh. The capacity is 35 tons per 24 hours and even this is lessened by interruptions, so that the results have

The Dolores Mill, Chihuahua, Mexico.

extraction of 64.6%. On fresh concentrate the extraction was 75.4%, on dump stuff it was as low as 32%. A profit of \$7,793 was made by re-treating the old cyanide dump.

In order to test the gravel deposits included within the concession, a Keystone traction drill was employed and 67 holes were put down. The average yield was 6 cents per yard, that is, it proved too low-grade to be dredged. In another locality the occurrence of a narrow channel about one mile long, averaging 12 cents per yard, was ascertained. The gravel deposits on the concession that may possibly be worth dredging consist of 40 or 50 miles of river valleys, varying in width from a few hundred feet to a mile. Evidently a great deal of testing is required.

The report gives an interesting list of the cost of supplies, of general expenses, of construction expenditure, of milling costs, and a great amount of useful information, not only to shareholders but to the mining profession. It is to be credited to H. F. Meserve, the general manager.

The Dolores Mines Co. issues an annual statement covering the business up to September 30, 1906. It is accompanied by the report of Mr. John B. Farish, until recently consulting engineer to this company. The early history of the undertaking is related, stress being laid on

been disappointing. It is proposed to erect another tubemill and to use the pans, of which there are four, as a reserve, for fine grinding. The pans were used for a long time for direct amalgamation, in association with two settlers. The cyanide plant itself proved a "heat-breaking affair," owing to the difficulty of getting lumber. Four agitation vats of 22 ft. diam. and 15 ft. depth are followed by three decanting vats of the same size, delivering to two settling tanks of 30 ft. diam. It is proposed to use a mechanical Dorr classifier to remedy the present imperfect classification.

The ore is a high-grade product, containing both silver and gold in the ratio of 40.6 to 59.4, taking silver at 65c. per ounce. The 9,793 tons of ore treated have yielded \$488,021, leaving \$309,066 in the tailing, which is to be

Richard Tangye.

Richard Tangye.

We are in receipt of an excellent portrait of Sir Richard Tangye, who died on October 14. By his achievements in mechanical engineering as applied to mining he won a position and a fame that were rendered illustrious by his striking personality. Born 73 years ago in the parish of Illogan, Cornwall, he came of a stock already distinguished by the possession of mechanical ability. As a youth he was first a clerk in an engineering works at Birmingham, the establishment becoming celebrated by reason of the fact that it made the first railroad car for the London & North Western Railway. In 1852 Birmingham had no such educational facilities as it now possesses, but young Tangye, and the two brothers who joined him shortly afterward, made the most of them. The brothers decided to go into business on their own account; Joseph Tangye designed a lathe; and in a room that was rented for four shillings per week and into which a revolving shaft projected, there was laid the foundation of a great engineering works. The Crimean war came, a schoolfellow was under contract with the Government to supply lint, and he wanted a machine that could do it rapidly and well. The Tangye brothers constructed one which served the purpose and thus they made their first step forward. But their great opportunity came when the *Great Eastern* was built. Sir Richard Tangye often remarked: "We launched the *Great Eastern*, and she launched us." The great Brunel had seen their hydraulic press for covering safety fuse with gutta-percha and when the monster white elephant of the seas was about to be launched, he remembered this fact, for everyone supposed that it would be necessary to moderate, not to accelerate, the descent of the big vessel into the water. Brunel's agent surprised them with a visit in 1856 and brought several of the machines, thinking that they would be of service in sending the *Great Eastern* down the slips. But the launching proved far otherwise; it became necessary to help the descent of the vessel, and it took three months to do it. A large order for jacks was placed with the Tangyes and their finances were put on a healthy basis. Then they moved to larger premises and secured independent motive power by the purchase of an old engine and boiler. They were joined by another brother who returned from America and soon afterward they engaged their first workman. The latter is still with the firm. They made a practical success of the differential pulley-block, got into a lawsuit and won it. In 1866 a warehouse was opened in London. Branch offices were established at Newcastle, Manchester, and Glasgow, and thus the business of the firm grew until it ramified into every quarter of the globe. In 1896 Richard Tangye was knighted in recognition of "services rendered to art education in Birmingham," but the reason for the honor lay deeper; it was due to the energetic man who had created a new branch of commerce founded on the mechanical arts, to the generous employer who was ever mindful of the best interests of those he employed, and to the public-spirited citizen who knew how to face poverty with courage and to wear riches without ostentation.

re-treated. There are remaining in the mine and on the dump 30,518 tons valued at \$1,431,021. A dump of tailing from amalgamation is estimated to contain 9,500 tons, worth gross \$309,066, so that the total reserve of all kinds amounts to 40,018 tons of a gross value of \$1,740,087. The net profit on the year's operations is \$267,621, but all this has been consumed in meeting sundry payments, in equipment, New York and London expenses, etc., so that the Company still owed \$173,374 on June 30. Mr. Farish outlines an additional expenditure on machinery, equipment, and improvements absolutely necessary, of \$78,500. Thus \$250,000 is needed. When this is done, he considers that the Company can maintain a profit in excess of \$20,000 per month, the present earning at the mine.

THE study of the earth indicates the continuation of processes of natural causation for a period of time as great, in relation to human history, as the distance of the heavenly bodies from us are, in relation to terrestrial standards of measurement. The abyss of time looms large as the abyss of space.

A NEW PROCESS of making quartz-glass in much larger quantities than has hitherto been possible has been discovered by the employment of high temperatures and pressures. In a quartz-glass vessel, gold, copper, or silver may be melted or even vaporized without injuring the receptacle. Quartz-glass expands scarcely at all; hence cold water will not break it, if poured over it even while hot. It transmits freely the ultra-violet rays of light, to which ordinary glass is almost opaque.

Diamond Mines in South Africa.

*Volcanic pipes in which diamonds are found are not peculiar to South Africa; similar formations have been discovered in New Zealand and quite recently in Connecticut; but it is only in South Africa that the diamond deposits have attained any economic importance. The so-called pipes in which the diamonds are found may be considered to be the material filling the craters of extinct mud volcanoes; this is not a very scientific description, but it will perhaps give, in a few words, an idea of the nature of the deposits.

For a long time it was supposed that diamond mines were only to be found in the neighborhood of Kimberley and in the district further to the east in the Orange River Colony, where the Jagersfontein and Koffyfontein pipes are situated. Within the last few years, however, diamond pipes have been found in many other parts of the country, and among them may be mentioned the Premier, Montrose, and Schuller pipes near Pretoria, in the Transvaal; the Lace and New Randfontein Reef pipes, near Kroonstad; and the Victor pipe, near Boshof, in the Orange River Colony; while the Peizer, New Weltevrede, and Frank Smith have been discovered to the northwest of Kimberley.

The price of diamonds has been controlled for some years by a powerful combination of diamond merchants in London; no difficulty has been found in maintaining the price, and since the Boer war, more particularly, the value per carat has been steadily rising. The question as to the possibility of keeping up the price of diamonds with a largely increased supply in prospect is one that is frequently asked, and leading authorities are agreed that at least twice the present annual supply could be absorbed without affecting the price per carat. It is considered, however, that as regards only the better class stones there will always be a demand. The value per carat of the diamonds recovered from the principal producing mines according to their latest report ranges from 23s. at the Premier to 69s. at the Dutoitspan. These figures are merely averages, and do not imply that there are no good stones found in the Premier mine or no poor ones at Dutoitspan. Every mine produces a certain amount of rubbish, worth about 9s. per carat, and the percentage of these poor stones found determines the average value of the yield. Thus at the last Premier meeting one of the directors pointed out that 75% of the total money value produced was represented by diamonds worth 52s. 6d. per carat, and the balance of 25% was made up of diamonds worth 9s. per carat.

Similar variations in value occur in the stones found in all diamond mines. As showing the gradual increase in the value per carat during the last twenty years, the following figures taken from the report of the New Jagersfontein mine may be of interest:

Year.	Average price realized per carat.	Year.	Average price realized per carat.
1887	28s. 4d.	1899	34s. 6.3d.
1891	37s. 2.3d.	1903	54s. 2.6d.
1895	31s. 1.0d.	1905	57s. 9.9d.

Since the issue of the report for 1905 the average price per carat has risen a further 5 per cent.

According to their annual report for 1890, the combined output from the De Beers mines and New Jagersfontein was about 1,550,000 carats, while for the corresponding period ending in 1889 the two companies produced together some 3,130,000 carats. At the outbreak of the Boer war, however, the diamond-mining industry became completely disorganized, and the mines have apparently hardly yet returned to the 1899 rate of production. Thus, according to the latest report of De Beers and New Jagersfontein

issued in 1905, it appears that the total number of carats won by these companies for the year was about 2,166,000 carats, or a decrease of 960,000 carats as compared with the figures for 1899. It should be understood that the figures are merely approximate, as it is impossible to find from the De Beers report for 1905 the number of carats actually recovered. As a set-off to the shortage in the output of these older companies, the Premier mine during 1905 won 845,652 carats, so that the total output from South Africa is at present very nearly what it was at the period just before the war. The other South African producers have been of little importance, but there are at least three mines which are expected one day to turn out large quantities of diamonds at a handsome profit. These are the Lace, the Roberts Victor and the New Randfontein Reefs mines. Of these, the Lace mine has already produced over 60,000 carats, is fully equipped with a washing plant, and has some 750,000 loads of blue ground on the floors. It will very shortly enter the regular producing stage, and a grade of from 14 to 20 carats per 100 loads washed is anticipated. The Roberts Victor and the New Randfontein Reefs are little more than prospecting ventures at present. In each case, however, a pipe has been found, and preliminary trials with a small washing plant point to a return of rather over 20 carats to the 100 loads, the average quality of the stones being very satisfactory.

Any estimate of the probable future annual production of diamonds must necessarily be a rough one, but it is apparent that there will be a large increase, even if no further new discoveries are made. By the year 1908, it may be assumed that the new mines discovered will be equipped and will have become regular producers. The probable increase in the output of diamonds for that year compared with the 1905 returns may be estimated as follows:

	Carats.
Premier Diamond Mine.....	1,200,000
Lace Diamond Mine.....	80,000
Roberts Victor Mine.....	100,000
New Randfontein Reefs Mine.....	200,000
Total increase.....	1,580,000

The returns from De Beers and Jagersfontein will be assumed to be the same as in 1905 (that is, 2,166,000 carats).

The Premier is by far the largest and most valuable individual diamond mine ever found in South Africa, and it is probably not an exaggeration to say that it is one of the most valuable mines of any kind ever discovered in the world. It is estimated that when its full plant is at work, it will make profit at the rate of £2,000,000 per year, the life of the mine on this basis being well over 50 years. Considerable interest will be taken in the attempt which is to be made at the Schuller mine to treat blue ground in tube-mills. The diamondiferous ground at this mine will not decompose when subjected to atmospheric agencies, so that it is necessary to disintegrate it by mechanical means. If crushers or rolls be used for this purpose the diamonds, which are brittle, although extremely hard, are broken as well as the matrix, but in the grinding action which takes place in a tube-mill it is thought that the diamonds will be separated from their enclosing minerals without being fractured. Experiments carried out on a small scale point to the feasibility of this arrangement, and if further experiments prove successful the adoption of tube-mills will revolutionize the treatment of blue ground on diamond mines by doing away with the expensive and tedious process of flooring, which adds both to the cost and the capital expenditure.

According to the new Transvaal diamond law, the Government has a right to take up 60% of the profits of any diamond mines found in the colony, after allowing for all capital expenditure necessary to equip the mine.

*From The Times, London, re-published and abstracted from South African Mines.

A New Application of Hydraulicking.

Written for the MINING AND SCIENTIFIC PRESS
By ETIENNE A. RITTER.

In the operation of a hydraulic placer mine it is often found necessary to drive a long cut through solid rock, in order to bring the head of the sluice-box at the lowest point of the bedrock.

This summer it was found necessary to make a cut of

Making a Cut for the Sluice-boxes.

this nature at the Bear mine, in the Cariboo mining district, British Columbia. The cut was to be 800 ft. long and 27 ft. deep at the deepest point; it was to be 10 ft. wide at the bottom. The cut had to be driven through partly disintegrated crystalline schist. The schist dipped

complish this work. One No. 6 monitor was set at the low end on stulls six feet above the ground, so as to leave room for the gravel—as it was washed away—to pass below it. Another monitor, No. 2, was used to wash away the schist as it was broken up.

From the elevation of the pen-stock, the water leaves the monitors with a pressure of 80 lb. per sq. in. The work was done in a series of cuts 100 ft. long, both monitors being advanced that distance and set again before starting to make the next cut.

The lower monitor literally lifted the schist, breaking the rock into fragments, while the upper giant was washing it away, offering continuously a new surface to the action of the lower monitor.

The minimum amount of powder was used in blasting and bulldozing, and only as a last resort to straighten the sides of the cut and to square the bottom. The shots were used mainly to loosen the ground so as to give the stream of water from the monitors a chance to be effective.

The 800 ft. of cut were driven between June 14 and August 20, at the rate of 5.88 ft. per shift, in including all the delays, such as the moving of the monitors, the relaying of the pipes, etc. At times, when the cut was already more than 20 ft. deep, the advance reached 8 ft. per shift for a week at a time. One monitor man and two Chinese for bulldozing and for working in the ground-sluice with rock-hooks, were employed on each shift.

The total cost of the work, without putting in the sluice-box, but graded and ready to lay down the sills in place, was \$3.30 per running foot. That same cut made by drilling, blasting, and mucking would have cost at least three times as much and taken twice as long.

A SENSITIVE direct reading level, called the Shaftometer, has been brought out by a Halifax company for lining up shafting, machinery, etc. It has a rigid gun-metal base 16 in. long, a glass tube 12 in. long, and a

Working at Both Ends, Making the Cut.

at 30° toward the upper end of the cut, breaking into layers from a quarter to three inches thick.

Messrs. B. A. Lasalle and John Wendle, who manage the property, decided to use the power of the water from their monitors to make that cut, taking advantage of the dip of the schist and of their stratification to ac-

complish this work. One No. 6 monitor was set at the low end on stulls six feet above the ground, so as to leave room for the gravel—as it was washed away—to pass below it. Another monitor, No. 2, was used to wash away the schist as it was broken up.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

A mortgage described the real estate as "the mineral land described in said deed," but the deed referred to gave no particular description of land as mineral lands but the court decided that the description in the mortgage would be construed as meaning the lands described in the deed that were in fact mineral lands.

Smith v. Vary, (Ala.) 41 South, 941.

The East Itasca Mining Co. was the owner of several lease hold terms of 30 years in properties located in Minnesota upon which it had made explorations for iron ore. The company thereafter assigned certain of the leases to the Cleveland Iron Co. under an agreement by which the iron company was to pay the mining company within six months from the date of the contract seven cents for each ton of ore averaging 56% of iron found and the work was to be conducted with reasonable diligence during a period of six months; the contract lease required the iron company to thoroughly develop the land for the purpose of determining the character and extent of the deposit of iron ore. In an action by the iron company against the mining company to recover an amount alleged to have been paid in mistake the court decided that the contract bound the iron company to pay the mining company seven cents per gross ton for all iron ore discovered or shown to exist by the completed explorations reasonably and fairly made within the specified time and that the contract did not contemplate the estimate of the actual quantity of ore existing within the premises, and it was further decided that explorations reasonably and fairly made based on a customary assumption that a drill-hole would properly disclose the condition of the earth within a radius of 100 ft., but therein subsequently developed that such assumption was erroneous, or other assumed facts on which the exploration was based were false, yet the iron company was not entitled to recover any part of the money paid on the theory that the payment was made by a mistake of fact.

Cleveland Cliffs Iron Co. v. Itasca Mining Co., 146 Fed. 232.

A mining lease provided that if any difference should arise between the lessor and the lessee as to any matter relating to the agreement, it should let it be referred to three disinterested persons. But it was decided that this agreement did not apply to a clause in the lease providing for an examination by three mining engineers to determine whether all the coal on the land capable of being mined had been paid for, so that the lease should not thereafter be required to make further payments on account of coal mined.

Henry v. Lehigh Valley Coal Company, (Pa.) 64 Atl. 635.

Where an applicant applies for a patent to a mining claim located by him, the Land Office, in the absence of the filing of an adverse claim, will indulge the presumption that no conflicting claims exist to the premises described in the application, but when an adverse claim is filed such presumption does not arise.

And in a controversy arising out of conflicting claims the court will presume that the location which is prior in time has prima facie the better right and that the burden of rebutting such presumption rests upon the party whose claim is subsequent in point of time. But the party whose claim is subsequent in point of time may show that at the time of the alleged location of the other party's claim the discovered point was located within the limits of an existing and valid location of another party, so that the ground was not at such time subject to location.

Lockhart v. Farrell (Utah) 86 Pac. 1077.

The statutes of Minnesota providing for the issuance of mineral leases have been held to be constitutional.

State v. Evans, (Minn.) 108 N. W. 958.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The black metallic mineral in quartz from Geiser, Oregon, marked A. G., is Graphite.

The two minerals from Yerington, Nev., marked A. J. T., are No. 1, Limonite; No. 2, specular Hematite.

The two rocks from Kingman, Ariz., marked F. C. S., are: No. 1, Feldspar, porphyry; No. 2, Augite diabase.

Rocks from Villa Grove, Colo., marked K. M. D., are No. 1, 2 and 3, Andesitic rocks, essentially alike; No. 4, Melanconite with malachite; No. 5, Granite.

The rock samples from J. L. H., of Isabella, Cal., are: No. 1, Slate; No. 2, decomposed Granite; No. 3, Gneiss, containing bornite and a little chalcopyrite.

Rocks from Palisade, Nev., marked S. F. P., are: No. 1, decomposed volcanic rock; No. 2, also altered volcanic. The green coloration is due to ferrous iron and not to copper.

Specimens from A. P., of Placerville, Cal., are: No. 1, Tale-schist, containing some manganese di-oxide; No. 2, Hematite; No. 3, brown Limonite; No. 4, earthy Limonite; No. 5, Serpentine; No. 6, Chlorite. There are no indications of tellurides or tungstates.

PLATINUM.—The price of ingot platinum per ounce increased from \$18.50 in December, 1904, to \$34 in September, 1906. In March, 1906, quotations of platinum were about 20% higher. The most promising fields for the production of the metal in the United States are southern Oregon and northern California, but in addition it is found in a number of other Western States and in Alaska, besides which "isolated occurrences of single nuggets or mere traces of the metal have been found" in a few Eastern States. The total production of platinum in the United States in 1905 is reported as 318 oz., valued at \$5,320, as compared with 200 oz. valued at \$4,160 in 1904. The imports of platinum in the United States during 1905 were valued at \$2,173,263, and in 1904 at \$1,879,155; 1903, \$2,055,933; 1902, \$1,987,980; 1901, \$1,695,895. It will be understood, of course, that these figures include both nuggets and manufactured products in various forms.—F. W. Horton in *Mineral Resources*.

THE MINERAL OUTPUT OF GREAT BRITAIN.—The Home Office has issued Part III of the Annual Report on the Mines and Quarries in the United Kingdom. It shows that the total value of the minerals raised during the year amounted to £95,870,723, a decrease of £1,606,916 as compared with 1904. This decrease is to be accounted for by a further fall in the average price of coal from 7s. 2.58d. per ton in 1904 to 6s. 11.38d. in 1905. The total output of coal was the highest hitherto recorded, namely, 236,128,936 tons, but the value was only £82,038,553, as against £83,851,784 in 1904 and £88,227,547 in 1903, when the output was less by more than 3½ and 5½ million tons respectively. The amount of coal available for home consumption was 168,968,291 tons, or 3.910 tons per head of the population, and 19,255,555 tons were used in the blast-furnaces for the manufacture of pig-iron, as against 17,535,337 tons in the previous year. Among the smaller items of production there is mention of 14 tons of silver ore, worth £306, and 15,981 tons of gold ore, worth £17,787. In 1904 the output of gold was valued at £68,576.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

PROCESS OF SEPARATING METALS FROM THEIR ORES.—No. 832,563; George H. Waterbury, Denver, Colorado.

The herein-described leaching process consisting in placing suitably pulverized ore in a tank containing a solution composed of water, common salt, alkali-metal nitrate and sulphurous acid, and subjecting the pulp thus formed to the action of air and steam simultaneously introduced.

MEANS FOR DISTRIBUTING MINE RESIDUES, &c.—832,714; August L. E. Bergert, Johannesburg, Transvaal.

In apparatus of the nature specified the combination of a carriage, a vertical rectangular frame having its top and bottom pivoted to said carriage, a shaft in said frame extending at right angles to the axis thereof and a boom having its rear end connected to said shaft.

APPARATUS FOR CONVERTING MATTES AND SPEISSES AND OTHER METALLIC COMPOUNDS.—No. 832,665; Herbert Haas, San Francisco, California.

A converter for converting copper and other mattes and the like having formed in the lining thereof conduits arranged about a central axis, and opening upwardly through said lining and in a direction oblique to the plane through

the orifice of the conduit and said axis and in the same angular direction therefrom, whereby the momentum imparted to the mass in the converter by the blast of air through each conduit is in the same direction of rotation, substantially as described.

METHOD OF EXTRACTING METAL VALUES FROM ORES.—No. 832,833; Ralph Baggaley, Pittsburg, Pennsylvania.

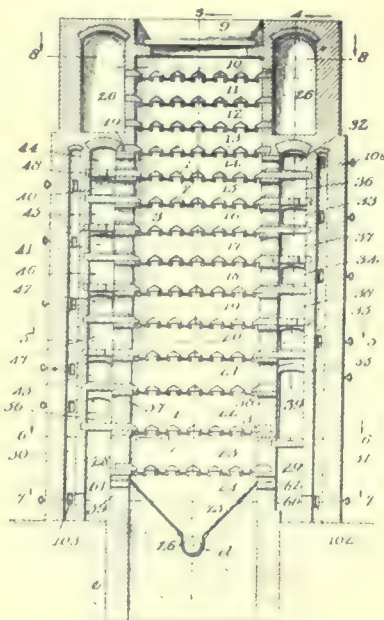

The method of extracting metal values from ores through liqation without carbonaceous fuel, which consists in feeding silicious ore to a bath of molten matte in excess of the amount that will flux with the constituents of the bath, and causing the excess portions of the ore to yield their values to the bath by liqation; substantially as described.

ROCK-DRILLING MACHINE OR ENGINE.—No. 832,791; Henry Hellman and Lewis C. Bayles, Johannesburg, Transvaal.

In a rock-drilling machine or engine, a rotatable power-cylinder having a side port at its forward end, a drill-steel slidably and non-rotatably held at said forward end of the power-cylinder, and having a passage extending longitudinally of said steel and communicating with the side port aforesaid, and a liquid-supply swivel loosely surrounding the forward end of the power-cylinder and having a port in communication with the side port aforesaid.

PROCESS OF TREATING SUBSTANCES BY THE AID OF HEAT.—No. 833,679; William B. Dennis, Blackbutte, Oregon.

The process of treating materials by the aid of heat, which consists in causing the material and the heating medium to travel from the cooler part of the apparatus to a hotter part thereof at rates of travel independent of each other, substantially as described.

Engineering Building of the University of Pennsylvania.

On October 19, the University of Pennsylvania opened the new building devoted to engineering education. The completion of this large and fully equipped structure marks the growing importance of the engineering profession in America.

The new building is the largest of the 70 buildings comprising the present university group and has a frontage of 300 ft. and a depth of 210 ft. at one end and 160 ft. at the other. Including equipment the building has cost upward of \$800,000. It is fireproof, three stories high, in addition to which there is a basement covering about a third of the entire site, bringing the total floor area to about 128,000 sq. ft. It is heated by a direct steam system, each room being heated by steam coils supplied with low-pressure steam exhausted from the university's light and heat station. Electrically driven fans, placed in the basement, force air into all the living rooms, and other fans in the attic exhaust it from the toilets. By sub-dividing the system into sections, each independent in itself, it is possible to operate only those associated with any part of the building which may be occupied at one time. The motors are controlled from points convenient to the instructors in charge of the departments served. The building is lighted by electricity and the scheme for illumination has been very carefully worked out, first with respect to securing the best lighting and second to providing a pleasing effect in the illumination.

UNIVERSITY OF PENNSYLVANIA, NEW BUILDING FOR THE ENGINEERING DEPARTMENTS, 1906.

Current is supplied during times of small demand directly from the central station, and when the demand is large from the local plant in the centre of the basement. This plant consists of one 25-h.p. and two 75-h.p. Westinghouse standard engines directly connected to General Electric generators. Steam for the engines is supplied from the central station and after being used by the engines is sent into the heating system of the building. The lighting of the halls and library is by 50-c.p. Meridian lamps. The classrooms are lit by clusters near the ceiling. The drawing rooms and laboratories are lit generally by five-ampere enclosed arc lamps placed about 15 ft. apart, each provided with opaque bottom shade and concentric diffuser.

The east end of the building is devoted to the civil engineering department and the west end to the mechanical engineering. In the basement are locker rooms, lavatories, machinery for heating and ventilating, storage battery rooms, laboratories for geodetic and hydraulic work, and testing materials for construction. At the front of the first floor, between the two main entrances, are the offices of the heads of the departments. The remainder of this floor is taken up by the various laboratories and testing rooms. Two large light wells terminate in skylights over the ground floor, and in this central space, which is about 50 by 200 ft., are the various workshops.

On the second floor a reference library and reading room occupy the central space at the front of the building. The

library and stack at one end will hold 20,000 volumes. The latter is flanked on either side by a series of recitation and lecture rooms, which are continued along both sides of this floor. Between the light wells at the centre of the building is a students' assembly room with about 2,500 sq. ft. of floor space. There are also a number of rooms for instructors along the south side of the light wells. The rear portion of this floor for nearly the entire length of the building is assigned to drawing rooms. A separate room will be allotted to each class and an individual desk to each student. In the extension on the west side is an alternating current laboratory, with facilities for two and three phase work and photometric work. An instrument repair-shop is adjacent to this laboratory.

On the third floor is a large room for the use of the engineering societies, and the general supply store and the library extend through the middle of the centre of the building, the space along the front being otherwise assigned to classrooms and to instructors' rooms along the south of the light wells. In the east and west wings spacious rooms have been set aside for engineering museums. The rear of this floor is also devoted to drawing rooms, which, like the drawing rooms on the second floor, will have the full advantage of north light through windows of ample dimensions.

Books Received.

A booklet entitled *ESTUDIOS DE MINERIA PRACTICA*, by M. Aurelio Denegri of the Lima School of Mines, has been received; it describes the practice at the mines at Collaraca, Peru.

THE DESIGN OF STEEL MILL BUILDINGS and calculation of stresses in framed structures by Milo S. Ketchum. Published by The Engineering News Co., New York. This is the second edition of a book that is intended to provide a short course in the calculation of stresses in framed structures, and to give a brief description of mill-building construction. In the discussion of the latter the aim has been to describe the methods and the material, together with a brief treatment of the design, and the estimates of weight and cost. The first edition proved most successful and to this one there is added a good deal of valuable material. The price of the book is \$4 and it

can be purchased through the MINING AND SCIENTIFIC PRESS.

THE COPPER HANDBOOK. A Manual of the Copper Industry of the World. Vol. VI. By Horace J. Stevens, Houghton, Mich. This valuable annual publication is a little late this year by reason of the illness of the author. Nevertheless, as heretofore, the volume is full of good matter and will strengthen the excellent reputation won by its predecessors. At a time like the present, when copper mining is in the ascendant, a statistical and technical compilation such as this ought to be on the desk of every mining man and investor. We have frequently had reason to test the data given concerning particular mining companies and it is not too much to say that Mr. Stevens has been proved to be invariably accurate and fair in his appraisal. The book is honestly and carefully done.

Publications Received.

CALIFORNIA MINERS' ASSOCIATION ANNUAL, 1905. This volume of proceedings is not less welcome for being late. The publication was about complete when the earthquake-fire in San Francisco destroyed the page proofs and the original copy. It was only with much difficulty that the matter now published was secured from various members. It is a creditable volume and contains much that is of interest.

Editorial.

THE CALIFORNIA MINERS' ASSOCIATION has been in session during the past week, but the California miners were not there. The attendance was restricted largely to the little coterie that has been keeping the Association alive during the last few years. As there was no definite program announced nor any papers of special interest, it was hardly to be expected that a representative attendance would be secured. The Association came into being and maintained its vitality for many years on an issue which is now dead; the question of hydraulic mining has been settled by the logic of events and more good can be done by dropping it for a while, until the test case, still pending, has been passed upon. In the meanwhile it is hopeless to expect the maintenance of general interest in a dead issue. Mining in California is not confined to hydraulicking, and the association will serve no particular usefulness until it manages to enlist the support of those who are mining vein gold and developing our important copper resources, not to mention a dozen other metals. Another matter of much greater importance to the Association than to us, is the refusal to permit publication of the papers that are read. These will probably appear a year hence, when their interest will have vanished. It is a small idea and defeats its purpose. Under existing conditions the Association is not likely to get papers of any moment. In fact, the Association needs a broader spirit, and a policy worthy of its proud title.

A GOOD WINE needs no bush, and a contribution such as that on 'West Australian Gold Mining Costs,' requires no endorsement in the editorial columns. It is one of the most useful papers on the economics of mining that this, or any other technical paper, has been enabled to publish. The personal equation in this case is splendidly confirmatory, for Mr. H. C. Hoover and the experienced mine managers who contributed the data, are among those who write with authority, and not as the scribes.

AMONG MINING enterprises none compare in interest with the excavating of Herculaneum, an undertaking about to be started by the Italian Government. This ancient city was buried under eighty feet of volcanic mud, which is now rock. Under this vast blanket lie buried the treasures of Greek art and literature of nearly two thousand years ago. The neighboring town of Pompeii was only a commercial town and a cheap place of amusement; it was to Herculaneum as Long Branch is to Newport. Pompeii was greatly damaged by earthquake long before its burial and it had been flimsily rebuilt, while Herculaneum when it was sealed to silence was a real centre of Greek civilization. Already one villa that has been unearthed has yielded a whole library

of papyri. The operations about to be systematically started ought to be as exciting as pocket mining in Calaveras county.

The Greatest Loss.

We have dwelt upon many features of the earthquake-fire that turned the sympathies of the world toward San Francisco in April. There remains one lesson and the chiefest of all, which we have reserved for special consideration. We refer to the loss of information in notes and manuscripts belonging to our engineer friends that, being written on perishable paper, without a duplicate, were consumed irretrievably in the flames. One family of engineers, a father and two sons, possessing a large stock of data gathered during two generations of intelligent activity, lost every scrap of the knowledge that they had expected to perpetuate in writing, for their own use and for other members of the family. Two engineers who were specialists in dredging and placer mining, possessed of a fine collection of drawings of machinery and records of practice, lost all these. Such instances could be multiplied, but it is not necessary; it requires but little imagination to appreciate the tremendous amount of individual knowledge in written form that perished utterly during the catastrophe. It was individual and that is why it exists no longer; had it been given to the profession, in the form of literary contributions to technical societies or to professional periodicals, it would be available today, for the benefit of the world at large and incidentally for the use of the men who hugged it closely to themselves. There is no waste so complete as the waste of experience, there is no gift more useful than the record of professional practice. There are men who, from mere laziness, postpone the act of systematizing the data they have collected and the publication of them in such form as will render the information of service to others; for these men one has sympathy, for to be lazy, especially after hard routine work, is human enough. But what shall be said of him who, collecting the little special knowledge that every man can accumulate after a few years of work, prefers deliberately to put it away in a safe, so that the exclusive benefit, if any, of it, may be his and his alone; he makes up his mind that no competitor shall have it and as for the rest of the world, such as students and the younger fellows whom it might help, why should he give it away to them for nothing? So the greedy tongues of flame sweep through his office and shrivel the selfish manuscript to a cinder. Shall we be sorry for such a man? Yes, but not for his loss of data so much as for the narrow spirit that chooses to live and work to itself.

Sentiment aside, a big fire proves the danger of omitting to duplicate valuable manuscript or even notes and drawings, and of all the ways of multiplying the record, none is so simple as that of putting it into print. Some of us lost the notes of twenty years, but when we realized it there came the pleasant reminder that the best of it had been already put together in the form of material published in transactions and books, of which there were so many copies and so scattered that no single disaster could destroy them all. Whether they were of small or large

value mattered little, they were ours, the children of our brain, and they lived, to be a part, however unimportant, of the general reference library of the profession. But we can meet the least altruistic engineer on his own ground, for we venture to say that he who never goes beyond the note-book stage or the individual record of work that is prepared for personal use, will never go far and rarely possesses as much as he would if he took the next step, namely, that sifting of data and refining of judgment which are required for the act of publication. Any man who has ever started to put together his information on a particular subject, need not to be reminded how soon he found it was like a garment only half woven, full of holes and unready for use. No one learns as much from his writing as the author, it is an education that continues throughout life, and it is the one that best brings home the limitation of human attainment. So, gentlemen of the profession, put the best that you have into print, for fear of otherwise losing it, and with a purpose generous as the inheritance of knowledge that has come to you without money and without price.

Maps.

Among the useful publications of the United States Geological Survey none are more valuable than the maps furnished by that scientific bureau. Not only are special sheets issued, but in every report and treatise one is sure to find one or more useful maps covering the regions described in the text. Maps are to the geologist and the mining engineer no less valuable than to the intelligence department of an army, and it is a notable fact that as a rule this necessary adjunct is omitted in many books and other publications where they are required to make the descriptions intelligible. Lately we have begun to insert small maps in the pages devoted to mining news; believing that the reference to them will be serviceable. It is astonishing to find so many valuable books of travel and of general information, dealing with unfamiliar regions, that are unprovided with such guides to a clear understanding. People write about distant countries and comparatively unknown localities without affording a clue as to the whereabouts of the places mentioned. Take, for instance, so useful a book as 'The Gold Mines of the World'—there is not a map in it, although it is obvious that to many of those that read it, the geography of the goldfields of Madagascar, Burmah, Korea, and even Alaska, India, and Australia, must be painfully vague. We have known the Mt. Morgan mine to be placed in New Zealand by an editor who is usually well-informed and we have seen Bendigo debited to Queensland by an authoritative technical journal. This is due to the scarcity of those little sketch maps that tie the unknown to the known, the new district to the old city, the ephemeral mining camp to the established centre of trade. To follow the development of the mining regions of the world it is necessary to begin with a correct notion of geographic relations. We purpose contributing to this need, and we hope that our readers will help by favoring us occasionally with a sketch map of their own locality, especially if it be the scene of unusual mining activity.

By the Way.

IN a recent address delivered by Mr. James Douglas at Columbia University, he said:

In deciding where it is most economical to reduce ore to metal, the cost of transporting the raw material, the fuel, and the finished product to the most profitable market are the determining factors.

There are some strange contradictions of this rule, as, for instance, the persistency with which the copper and brass trade adhere to the Naugatuck valley in Connecticut. It has been an old industry there, for Warden in 1819 says: "Metal buttons have been manufactured at Waterbury and New Haven of which the annual amount has been estimated at \$100,000." And there are ill-suited locations of some of our large iron works which were started originally near some small iron deposits now exhausted, or on a water power, too trifling to be used today, but which survive as geographical anomalies because the necessity is not yet urgent enough to oblige the owners to wipe out the large capital invested. But our more progressive corporations are taking this radical step, as instanced by the owners of the Lackawanna Steel Co., whose owners have transferred their works from Scranton to Buffalo, while their name alone perpetuates their former prosperous existence in the heart of Pennsylvania. If we assume, for instance, that at present two tons of Lake Superior ore make one ton of pig iron, and that one ton of fuel is consumed in reducing them to one ton of pig, and this pig iron is used up in the East, then two tons of cheaply handled ore are transferred to Pittsburgh, whereas if that ore were reduced at the mine, one ton of fuel, whose transportation (owing to its bulk) is more costly than that of a ton of ore, would have to be carried from Pennsylvania or Ohio; and one ton of pig of high value, and therefore commanding a higher freight rate, would of necessity be shipped back to the Eastern market. Under either condition four tons of freight must be shipped to lay down a ton of pig in Pittsburgh—two tons from west to east, and two from east to west; but the east-bound ore can be handled with less loss and at less cost than coal and coke could be carried West and pig iron East. Therefore, up to the limit of the demand of the Eastern market for pig iron, it is cheaper to make it of Lake Superior ore in Pittsburgh than to make it on Lake Superior. But the Western market is rapidly growing, and new works are being laid out on Lake Michigan, rather than either in the heart of Pennsylvania or on Lake Erie, for both Michigan and Minnesota ore can be laid down more cheaply on the shores of Lake Michigan than at any point in Pennsylvania or Ohio; and though the great central coal basin does not yield a good coking coal, it does produce cheap fuel for converting pig into finished product. Last year the shipments of iron ore from Lake Superior amounted to 34,353,456 tons. Of this, 84.4% was transferred inland by rail to ports on Lake Erie; the balance—5,369,098—was shipped to points on Lake Michigan.

As, however, the West grows—and the West is shifting always to points still farther west—its demands for iron grow almost more rapidly than the East, and the centre of manufacturing will continue to move westward. This tendency we see in the rapid expansion of the only large iron and steel organization west of the Missouri—the Colorado Fuel & Iron Co. While in 1900 its furnaces at Pueblo made only 150,204 tons of pig iron, they made 407,774 tons in 1905. And yet these furnaces depend on long distance freight for their supply of ore! Some of it comes over a haul of 700 miles from southern New Mexico, and much of it comes from Wyoming and distant points in Colorado. But the fuel supply is near at hand in the Trinidad coalfield.

We know of no iron deposits in the West comparable in size to those on Lake Superior, but there are many which can be profitably worked. Though within our own territory west of the Great Salt Lake Basin we have no good coking coal, our neighbors to the north can supply it, or we can draw it from New South Wales, which already has shipped coal for railroad purposes to the Pacific Coast. From our other neighbor on the south, should iron and steel works be started on the west coast, we can draw ore from the large deposits said to lie on the very seashore near Acapulco, for distance is being rapidly obliterated by steam, and by it also let us hope international selfishness and commercial exclusiveness. Literature is tending to unify the race and commerce, through the railroad and steamboat, is another beneficent force working to the same end. As people come to know one another better, under a process of natural selection, they will surely imitate and adopt each other's better qualities, and, without losing their national idiosyncracies, acquire a higher cosmopolitan character.

In a recent issue of *The Outlook*, the elections are interpreted thus: Politically the country has been growing democratic; industrially it has been growing autocratic. The discovery of natural forces and the laws which govern them, the growing ability to use them in the service of men, the recently developed ability to co-operate in organized industry, the invention of division of labor, the vast increase of wealth—an increase more rapid than the increase of moral intelligence properly to value and rightly to use it—have combined to create great captains of industry, who have taken the place of the political commanders of the older epoch. We have abolished kings and substituted railway kings; have abolished lords and substituted coal barons. Our industrial systems are founded on the principles of feudalism, with this difference: The industrial overlord owes no protection to his men, and may discharge them when he will; they owe no loyalty to their overlord, and may leave his service when they will. But they have no share in the direction of the industry, and only incidentally and indirectly, if at all, any share in its profits over and above the necessary cost of production.

These overlords are sometimes high-minded, noble-spirited, generous men; they are sometimes mean, niggardly, unscrupulous men; but whatever their character, they are overlords. Their prosperity often depends on legislation. Sometimes unscrupulous politicians threaten them with unjust legislation against which they must protect themselves; sometimes they desire special legislation to promote their industries. Hence the 'boss' and the 'machine.' All political parties must have leaders; when the leader becomes a servant of the plutocracy, he is a 'boss.' All political parties must have organization. When the organization becomes tributary to the plutocracy, it is a 'machine.'

Thus there have been growing up in America simultaneously, neither really conscious of the growth of the other, two powers—Democracy and Plutocracy. There is an irrepressible controversy between them. One of them will eventually destroy the other. Shall government become autocratic, or shall industry become democratic? This is the fundamental question before the American people today.

Observe: The people do not object to kings merely when they misbehave. They object to kings good and bad. They do not object to plutocrats merely when they misbehave. They object to plutocrats good and bad. As they objected to the concentration of political power in an oligarchy, so they object to the concentration of industrial power in a plutocracy.

Special Correspondence.

London.

Old Cornish Mines Re-Opened—Wheal Buller—Rich Ore in Dolcoath—Decreased Tin Production From the Malay States—An Old Irish Copper Mine—West African Results—Half-Yearly Report From Mt. Lyell—Mt. Cattlin Copper Co.—A West Australian Lament—Mexican Returns.

Cornish mining continues decidedly on the up-grade. It is said that the capital for Botallack Mines Ltd. was largely over-subscribed. Other resuscitations are to be heard of shortly. According to *The Cornish Post*, the once famous and profitable copper and tin mine Wheal Buller, in the parish of Redruth, is about to be re-worked on the limited liability principle. It is proposed to form a company with a capital about £50,000, but it is not probable that one-half of this sum will be required to re-open the property and bring it into a producing stage. Wheal Buller, which adjoins the Basset mines, was started in October, 1848, with a capital of £1,280 in 10-shares. The company commenced to pay dividends four months later; altogether the shareholders reaped £243,392, or £1,910 per share. The first dividend was £10 per share. When the number of shares was increased to 250, they were sold at £1,000 each. In its progress, no mine of those times was so rapidly developed and placed so soon at the head of the industry. The principal lode (copper) became productive at a shallow depth, yielding 20 tons of ore per fathom, at 20 fathoms only below the adit level. Altogether 83,910 tons of copper ore were sold, realizing £484,770. Immediately under the huge bed of copper, tin was discovered and £95,195 was secured by the sale of it. The tin lodes were found in the eastern part of the sett, while the pumping-engine had been placed on the opposite side—over 200 fathoms away. This necessitated pumping by the aid of flat rods, which frequently broke down; and although the miners were actually engaged in raising tin from a productive lode, the then executive suspended operations rather than go to the cost of erecting a pumping-engine in the eastern part of the property. The pumping charges were small, owing to the shallowness of the mine and of its granite formation. The lease of Wheal Buller is most liberal. It is granted by General Sir Redvers Buller for a term of 40 years, and Cornishmen will be glad to know that dues will be paid on profits only.

At the bottom of Dolcoath, the lode is reported to be producing 1 cwt. tin per ton, and it is said that £500,000 worth of tin ground has been blocked out for stoping. These bright prospects at the bottom of the mine are considered to justify the re-sinking of Williams' shaft. Cornwall is endeavoring to do something to make up the deficiency in the Straits' supplies which has largely accounted for the rise in the price of tin. Official reports from the Federated Malay States show that in the first nine months of the current year the exports of tin, including metal contents of ore shipped, amounted to 608,381 pikuls, as compared with 636,191 pikuls in the corresponding period of last year and very much larger quantities previously. (The pikul is equal to 133½ lb.) The Irish copper concern, the Bonmahon Copper Mines Development Syndicate, whose capital is £30,000, is about to expand into a company with a capital of £200,000, of which £75,000 has been guaranteed for immediate working capital, and £40,000 in shares will be held in reserve. It is claimed that the estimates of the prospectus have been so far confirmed, and that there is an unlimited supply of ore averaging 4% copper, which can be easily mined and concentrated. At first it was feared that sea-

water might be encountered in the mine, but from a recent report it appears that the greatest trouble experienced was not in the extraction of the water, but in the extraction of the old timber in the shafts. The timbering in the days of the old company must have been executed by past-masters of their craft, and the pumping machinery, under the present conditions, could not be installed with the system of timbering adopted by the old miners. The timber, which is as hard today, if not harder, than it was at the date it was put into the mine, had not only to be cut out, but in some cases had to be blasted out.

The Abosso Gold Mining Co. occupies a unique position as regards West African properties in having reached the dividend-paying stage. During the financial year to June 30 there were crushed 44,704 tons from which 35,689 oz. fine gold were recovered, realizing £152,256. The result was a profit of £58,637, from which a dividend of 10% is to be paid. As much as 92.15% of the gold contents was extracted, and the slime is still to be treated. The average yield per ton crushed was 15.96 dwt., and the total expenditure, including maintenance of works and mine redemption, averaged £2 per ton. The ore reserves amounted to 110,376 tons, of an average value of over 18 dwt. per ton. This is 35,723 tons in excess of the ore developed a year previously, and represents two and a half years' supply for the mill at the present rate of crushing.

A cable from the head office of the Mount Lyell Mining & Railway Co. in Melbourne gives the totals of the ore treated during half-year ended September 30: Mount Lyell mine, 133,668 tons; North Mount Lyell mine, 58,564 tons; total, 192,232 tons, averaging 2.52% copper, 1.71 oz. silver, and 0.067 oz. gold. Metal-bearing fluxes, 6,450 tons. Purchased ore, 607 tons. Produced, 4,491 tons blister copper. Operations (other than chemical works) for the half-year have resulted in a net profit of £239,397. According to estimates submitted by the general manager, the position of the ore reserves at September 30 was as follows: Mount Lyell mine: Available for open-cut extraction down to No. 5 level, 1,342,000 tons. Estimated average contents: 0.6% copper, 1.92 oz. silver, 0.044 oz. gold per ton. Available by underground mining below No. 4 level, 2,614,000 tons. Estimated average contents: 0.52% copper, 1.97 oz. silver, 0.025 oz. gold per ton. North Mount Lyell mine: Taking North Mount Lyell ore reserves as inclusive of extension to Lyell Tharsis mine, the figures are as follows: Available by means of open-cuts, 5,293 tons; available for underground mining in main orebody, sub-stopes, and subsidiary bodies, 65,367 tons; in new developments, including east stopes sub-stopes No. 1 and 2 above and below 700 ft. level, 244,954 tons; Lyell Tharsis mine, 6,547 tons; total, 322,161 tons, representing an accession of 189,000 tons during the half-year less amount extracted and smelted during the period. Large portion of last figure, however, is represented by reserves estimated to exist below the 700-ft. level.

The Mount Cattlin Copper Mining Co. has been formed with a capital of £200,000 in £1 shares, which are offered for subscription at par, to acquire and work the copper mining property known as the Mount Cattlin mine, situated at Ravensthorpe, in the Phillips River district of Western Australia. The property comprises an area of about 50 acres, and prior to its acquisition by the present owners, the Phillips River Gold & Copper Co., Ltd., a considerable amount of prospecting work was done on the property. Since that date active development work has been carried out, under the direction of their mining manager, Mr. F. W. Morgan, the outlay being estimated to have been upward of £20,000. The property has been examined and reported upon by Mr. F. W. Morgan, Mr. G. C. Klug (late manager of the

Great Boulder Perseverance, who is now general manager of the Phillips River Gold & Copper Co., Ltd.), and Mr. W. H. Trewartha James. Mr. Klug states that the approximate tonnage and value of ore reserves is 21,200 tons, averaging 5% copper, 5 dwt. gold, and 9 dwt. silver per ton, and expresses the opinion that the mine will develop into a fine property; Mr. James, after carefully examining the property, cabled that on the present appearance and prospects he considers the Mount Cattlin a valuable property and a very desirable acquisition; while Mr. Morgan reports that there are three shoots of ore and estimates the tonnage of the ore reserves at 20,500 tons, containing 5.12% copper, 4 dwt. gold, 9 dwt. silver per ton, without taking into account many thousand tons of low-grade ore. Arrangements are to be made with the Phillips River Co. for treating the ore at their smelter at Ravensthorpe, and the Company is expected to

of bullion produced, \$146,858; concentrates, \$76,571; ore shipped to smelter, \$528,639; receipts from rents and other sources, \$548. Profit at the mine, \$474,713. The report of El Oro is also to hand. The No. 1 mill ran 28 days, No. 2 mill ran 29 days, and together crushed 22,100 tons of ore, producing \$171,469, less working expenses, \$95,868, and development \$11,056; profit, \$64,545; profit from the railway, \$11,797; total profit in Mexico, \$76,342. The general manager adds: "More than usual amount of precipitates remaining on hand in zinc-boxes at the end of the month."

Calumet, Michigan.

Calumet & Hecla Raises Wages.—Big Dividends From the Copper Mines.—Lake Superior Men Operating in Arizona.—Another Incorporation.—Arcadian Transfer to the Quincy.—The Mohawk Dividend.—Railroad Construction.

Announcement of a 10% increase in the wages of all employees at the mines and stamp-mills of the Calumet & Hecla Mining Co. was made a few days ago, the raise to become effective in January. This affects between 5,000 and 6,000 men and it is estimated that it will increase the payroll fully \$500,000 per annum. The Calumet & Hecla Co. has always been noted for liberality toward its employees; it is one of the most magnanimous corporations in the world; not only does it pay the highest wages in the Lake Superior Copper district, but it furnishes its employees with dwellings, hospital service, and other things at nominal prices, and provides a free library, baths, etc.

Although the Lake Superior mines are now working the largest forces in their history, and wages are the highest ever known, there is room for more men. But with the advent of winter and consequent curtailment of surface work more men will be available underground. The prosperity resulting from the present price of copper is not confined to the mining companies, nor to the employees of any single corporation, but is being shared by all alike. The Copper Range Consolidated, Wolverine, Mohawk, Tamarack, Osceola, Isle Royal, Quincy, and other mining companies have increased the wages of their men at different periods during the past few months. The Calumet & Hecla, however, always pays slightly higher wages than the other mines and its action in adding another 10% on the first of next year may eventually result in further increases by the other corporations, in which event upward of 18,000 men would be affected.

Laboring men are very prosperous in all the copper mining districts, owing to the strength of the metal, and wages have recently been advanced in the Butte and Bisbee districts. Dividend payments by the copper mines this year will break all records in the Lake Superior district. With the payment of its \$20 quarterly dividend the latter part of this month, the Calumet & Hecla's disbursements to its shareholders will have reached \$99,350,000, a record without equal in the annals of the mining industry. Dividend payments by leading mines in the next four weeks will be as follows: Calumet & Hecla, \$2,000,000; Calumet & Arizona, \$800,000; North Butte, \$800,000; Copper Range Consolidated, \$767,562; Quincy, \$250,000. These mines, with the exception of Calumet & Arizona and North Butte, are situated in the Lake Superior district, and the other two are dominated by Lake Superior capital.

The organization of the Superior & Boston Copper Co. was perfected here a few days ago. The new concern is to take over the property of the Globe & Arizona Development Co., together with 20 additional claims, making a total of 41 full and fractional claims adjoining, on the east, the Old Dominion and the Arizona-Commercial properties, at Globe, Arizona. The new company is

commence smelting operations at an early date. — The chairman of Zoroastrian Limited, at the meeting for reconstruction of the Company (for the third time) lately, in referring to their disappointments and the state of "suspended animation" observable in West Australian mining, remarked that their experience was the same as that of other companies in the Bardoc district. The reef everywhere was erratic in value; they got places exceedingly rich, which lured them on to further expenditure, and when they had embarked on that expenditure they found it would have been better to have left it alone. The conclusion to which the directors had arrived was that under the present conditions of labor the Zoroastrian would not pay to work. They had a mine admirably equipped with machinery, and they were doing a good business in public crushing and cyaniding other people's tailings. By that means they were almost paying their expenses in Western Australia. He did not want to indulge in eloquence at the expense of the Labor Party in Australia, but the trade unions there insisted upon the payment of £4 per man per week for underground labor. That was all very well for the rich mines of Kalgoorlie with 1-oz. and 1½-oz. ore, but to a struggling undertaking up-country like the Zoroastrian, and hundreds of others, such a charge was prohibitive.

For results Esperanza (Mexico) is still to the fore, as may be seen from the return for October: The mill ran 29 days and crushed 13,810 tons of dry ore; shipped to smelter, 6,401 tons of dry ore; estimated realizable value

capitalized for \$1,500,000, in 150,000 shares of \$10 each. Of this amount 15,000 shares went in part payment for the properties and the balance of 135,000 shares was sold at one dollar each, nine dollars being subject to call. The stock was heavily over-subscribed in a few days. The officers are: President, James Chynoweth, general manager of the Centennial and Allouez mines; secretary and treasurer, William G. Rice. In addition, the board of directors includes Norman W. Haire, general manager of the Bigelow mines, Henry V. Snell, general manager of the Arizona Commercial, and J. H. Rice, vice president of the Houghton National Bank. The main offices of the company will be at Houghton. Recent developments on the 400 and 500-ft. levels of the Black Hawk claim of the Arizona Commercial prove the orebody to a point within 14 ft. of the endline of the Superior & Boston ground. The new railroad, built by the Arizona Commercial to its Black Hawk shaft last summer, gives the Superior & Boston standard-gauge railroad facilities.

There has been filed in the county office at Houghton a deed transferring from Arcadian to the Quincy 800 acres of land, described as follows: The north half of Section 1, 55-33, and the north half of the southwest quarter of Section 13, 55-34. The document is dated November 19, and is signed by Albert C. Burrage, president of the Arcadian, and Charles D. Burrage, secretary of the same corporation. The consideration named is \$750,000 in hand paid by the Quincy, the receipt of which is acknowledged. The deed guaranteed the land to be free from all encumbrances except the street railway, steam and wagon-roads holding rights of way across it.

There is much speculation regarding the dividend which the directors of the Mohawk Mining Co. will declare this month and which will be paid to the shareholders in January. The Mohawk's last dividend was three dollars per share and the previous one two dollars, making \$500,000 for this year. It is intimated that the next dividend will be four dollars. The situation at the mine is quite encouraging, despite the low returns in copper secured from the Kearsarge lode. The construction next year should be light and production should be considerably increased.

Toronto, Canada.

Work at Manitou Lake.—News From Cobalt.—Several Interesting Strikes.—Copper Mining in Hastings County.—A Smelter Now in Operation.

Development work continues at the leading gold mines of the Manitou Lake district in northwestern Ontario, though no specially noteworthy strikes are reported. At the Laurentian, driving on the east vein is being done in a southerly direction and rich ore is being taken out.—Dryden Smith, manager of the Little Master, is exploring the black quartz vein with satisfactory result.—The shaft of the Paymaster mine is being put down toward the 400-ft. level under the direction of Mr. Manley, the acting manager.—At the Volcanic Reef, another contract for driving north from the shaft has been let.

Recent changes of ownership and capitalizations of Cobalt mines have in many cases resulted in large purchases of machinery to increase the production. The Cleveland-Cobalt Co., owning 114 acres on Clear Lake, has ordered \$40,000 worth of machinery from the A. R. Williams Co., Toronto, and Allis-Chalmers-Bullock, including a gas-producer plant of three units and air-compressors. They will sink three shafts on the property. A vein which showed traces of silver at 25 ft. has proved rich in native silver and argentite at 45 ft. depth and widened to over five feet.

The Clear Lake Mining Co., which recently sold

45 acres to the Cleveland-Cobalt, retains 60 acres, known as the Timmins Extension, and has ordered an air-compressor and steam plant from the A. R. Williams Co. for sinking a shaft.—At the McKinley-Darragh-Savage mine, on Cobalt lake, a coffer-dam is being built 100 ft. from the shore at the south end of the lake at a cost of \$20,000. The intervening space will then be drained to facilitate the working of the veins now under water. A vein six inches wide, rich in native silver, has been found on the 50-ft. level. The shaft on vein No. 3 is down 30 ft. and the ore is rich in sulphide.

The first carload of ore shipped from the Foster mine has yielded returns of \$26,070.—The Green-Meehan on November 27 shipped its second carload of ore to the smelter. A report received from the manager, Charles O'Connell, states that in No. 1 vein rich ore has been struck 125 ft. from the north end of the shoot now being worked, leading to the conclusion that the orebody covers the interval.—Col. A. M. Hay, an experienced miner and one of the first on the ground at Cobalt, has been chosen president of the Tretheway company, and S. A. Wickett vice-president.—A good find has been made on the Mackay property, near Cobalt, ore carrying 200 oz. silver per ton having been struck at 25 ft. depth. The vein shows a width of two feet.

At the Eldorado copper mine, in Hastings county, Ontario, owned by the Medina Gold Mining Co., of which James B. Cook is superintendent, work has been energetically pushed since the installation of the smelter this summer. The shaft, which is 40 by 8 ft. wide, is down 140 ft. The width of the vein is 7 to 8 ft., the ore being chalcopryite, and carrying an average of 7% copper. There is a daily output of 30 to 35 tons, which is reduced to matte in the smelter and shipped for further treatment to New Jersey. The plant is complete and includes an electric lighting outfit. An additional five-drill air-compressor is being put in.—Other valuable copper deposits have lately been discovered in this district. James Best has begun the development of a 3-ft. vein, which grows wider as it is followed, at Bancroft.

Another find of rich copper ore has been made at Queensboro. The successful operation of the Eldorado smelter is likely to develop an important copper-mining industry in the district, and prospectors are eagerly searching for copper ore deposits.

Leadville, Colorado.

Boston Interest in Leadville.—To Re-open Sugar Loaf.—The Dinero Adit.—More Custom Mills.—Shortage of Cars and Lack of Labor.

The possibilities and advantages of Leadville mining properties as a field for investment is attracting Boston capitalists, and an investigation of the district is now being made by representatives from the Massachusetts metropolis. Leadville, as compared with other Western mining centres, is but little known in Boston and other New England towns. But the investigations made by the Eastern representatives have proved surprising to the visitors. Boston is principally interested in copper mines, and the Boston Stock Exchange every year handles more copper stocks than any other city in the country, not excepting New York. In previous years but little interest was shown in gold and silver properties, the capitalists preferring to put their money into well-known paying copper mines in Michigan. Of late the trend of popular opinion has changed, and gold and silver mines are receiving attention as well. Messrs.

K. P. Crawford and J. F. Dearborn are the Boston representatives here at present.

A new tunnel proposition, already well under way, to develop the mines on Sugar Loaf Mtn., has been organized by D. M. Gray and associates. Mr. Gray will manage the proposition, and states that the adit will be driven 3,045 ft. as a minimum. This adit will bear the relation to Sugar Loaf that the Yak tunnel bears to Carbonate, Breece, and Fryer hills. Sugar Loaf Mtn. has produced approximately \$11,000,000 to date, and of this amount the Dinero is stated to have contributed nearly \$1,500,000 from its two principal mines, the Dinero and Buckeye State. A number of years since work on the lower levels was discontinued on account of a heavy inflow of water containing a large amount of sulphuric acid. It was found impracticable to handle the acid water and development was limited to the upper workings. The adit will be run from the northeast bore of the mountain and will cut the vein at a depth of 900 ft., which will amount to 500 ft. below the present workings. The company contemplates installing an electric plant, which will provide power for drills, hoists, and

the prospects for a large increase in tonnage seem assured.

The success that has attended the different custom mills erected in the district has induced others to come into the market. Among the new mills are the Boston & Arizona and Damascus. The buildings for the former are completed and the machinery will be installed by the middle of December. This mill will handle 100 tons daily by concentration and will treat custom ores. The Damascus mill will be equipped with magnetic separators, principally to treat products from other mills. The shortage of cars for shipping ore to the smelters appears to be of a serious nature at this writing. Not only has the dearth of cars been a serious drawback to producing mines, but the output of many important producers has been also curtailed for many weeks due alone to the fact that the smelters were not able to treat all ores offered. The explanation made is that the scarcity of labor at the Arkansas Valley smelter leaves several units of the plant idle that could otherwise be utilized.

Butte, Montana.

Sale of Barnes-King Mines—Important Transfer—Heinze and the Snow Storm—Reports From That Mine—The Goldsmith Co.—Butte & Bacorn—Encouraging Results—Jennie Dell Again—Copper in the Cable District—North Butte's Development.

The Barnes-King Development Co., organized in Butte during the past week, has purchased the Kendall mine and 22 other gold claims situated 21 miles from Lewistown, Mont., paying \$1,200,000 for the property, which includes the mines named, a ranch of several hundred acres, a cyanide mill with a capacity of about 225 tons per day, and a good surface equipment at the mine. The new company is capitalized for 400,000 shares of \$5 each. The flotation was made in Butte and New York and the entire stock over-subscribed several times. In Butte alone \$1,400,000 was subscribed, as the property and the men at the head of the new company are well known here. It is the intention of the company to enlarge and re-model the mill, develop the mine and increase the daily output to about 450 tons of ore. At present the output is about 210 tons per day. The mine has been a constant producer for five or six years and has paid monthly dividends of \$20,000 to \$25,000. It is estimated that there are more than 2,000,000 tons of ore in sight. The engineers who examined the mine, sampled the entire workings and the assays have run from \$3 to \$45, the average being about \$14 per ton. They also reported that the cost of mining has been less than \$1.50 and of milling about 75 cents, and that with the improvements to be made the entire cost of both mining and milling should not be more than \$2.25 per ton. In their opinion, with an expenditure of \$150,000 the mine could be made to produce 400 tons per day. The property is opened with a shaft 250 ft. deep, and with tunnels and drifts 15,000 ft. in length. Among the engineers and experts who have examined and reported favorably on the property are Walter Harvey Weed of the United States Geological Survey, J. Parke Channing of the Tennessee Copper Co., and several engineers of the Amalgamated Copper Co., Amalgamated and Daly Estate interests control the enterprise. The directors include H. Carroll Brown, a banker of Baltimore; J. L. Gerard and W. T. Harkness of New York; J. C. Lalor of Anaconda, manager of the Daly Estate, and W. W. Cheely, a Butte publisher. The Barnes-King mines are the biggest gold properties in Montana.

W. D. Greenough, manager of the Snow Storm mine and one of its principal owners, says that F. Augustus Heinze has been negotiating for the purchase of a controlling interest, and offered to take the stock of Mr.

Montana.

transportation. A mill for treating the low-grade ore, along with the larger portion of the mammoth dump, which is estimated to contain several million dollars worth of ore, will be erected. The company was incorporated at \$5,000,000 under the laws of Arizona, and is styled The Dinero Consolidated Mining & Tunnel Co. The general offices of the company are at Kansas City, Mo., with the mine office in this city. The adit will be the second longest in the district, and its network of laterals will ultimately be run to develop the adjoining properties. Thus it will rival the Yak tunnel in importance. The amount of territory owned and leased by the company amounts to a little less than 100 acres, and includes the Dinero placer claim, Dinero, Orinoco, Inez, Bull Dog, Pitcher, Buckeye State, Michigan Boy, and other lode claims. On the whole the Dinero is one of the strongest and most important companies that has been organized in the district for many years past, and will develop one of the most promising portions of the Leadville district.

The finding of considerable ore of shipping value in the tributary sections such as Big and Little English, French, Dutch, and Empire gulches during the present season has assisted materially in enlarging the area of the productive district. In Empire gulch the owners of the Eclipse leased—some months ago—their property to Peter Rawson. Under this lease more than 25 tons are being shipped daily to the Arkansas Valley smelter and

Greenough and his associates, amounting to more than 800,000 shares, but they could not agree on a price. Mr. Greenough adds: "There are close to 2,000,000 tons of ore blocked out in the mine, and 50,000 tons are on the dump at the mouth of No. 3 tunnel. We have developed an orebody 850 ft. long, 623 ft. high, and 40 ft. in average width, with good ore in the face of all the drifts. We now have enough ore blocked out to run continuously for 10 years, and are blocking out more daily. This great mass of ore will average 5% copper and 6 oz. silver per ton. Considerable of it is high-grade ore, and I do not believe any of it will go under 3% copper and 1 oz. silver. Taking the lowest grade of ore, at present metal prices, it would net the company about \$7 per ton. I believe that the Snow Storm has greater possibilities than any mine in the Cœur d'Alene country, and it is certain that none of them have the immense tonnage of ore blocked out where it can be measured. The Snow Storm has an intrinsic value of \$9 per share of measurable ore, which has been carefully sampled. J. C. Adams, superintendent of the Boston & Montana mines, says there is \$9.50 per share, net money, blocked out and in sight, and in his opinion the No. 4 tunnel, which will cut the orebody 550 ft. deeper than the present workings, will undoubtedly find an enriched zone of copper glance. We are working on this tunnel and expect to complete it in about a year. We are also extending our drift on the No. 3 level west, and, as all indications of the orebody are to the effect that it rakes to the west, we expect to encounter the black sulphide on this level which occurs on the upper levels. Our new air-compressor is now completed and running nicely, and we expect to start the new 750-ton tramway within another week. We will then drop all of our ore to the No. 3 tunnel and put it over the new tramway. This ore should be mined and put on the cars for not to exceed \$1.25 per ton. The Snow Storm will be able to mine and make copper at a profit when the metal price is so low as to compel many other mines to close."

James W. Neill is engaged in making an examination of the Goldsmith mines for the new Goldsmith Mining Co. If the report is favorable the company will take over the properties and proceed to develop the mine to a depth of 1,200 ft. The shaft on the Goldsmith is at present but 400 ft. deep, but to that depth the mine has yielded a great quantity of silver ore. Regular shipments are being made by the old owners to the East Helena smelter. The ore taken from the lowest level runs high in silver and about 3% copper. The Goldsmith is on the famous Rainbow lode, from which silver ore has been mined for many years, and it is the opinion of mining men that with sufficient depth the veins will be found rich in copper. Frank M. Sullivan, who floated the East Butte Mining Co. and other important mining concerns, is largely interested in the Goldsmith.

As the cross-cut continues in the Butte & Bacorn ground from the Colleen Bawn shaft, the company is growing more confident that commercial copper ore will be struck even at a depth of 300 ft. One stringer of ore 18 in. wide and another six inches in width have been cut. The value of the ore averages 31.2 oz. silver per ton and 3.15% copper. Picked samples returned 44.6 oz. silver, \$7.20 in gold, 4% copper and 4.6% lead. The company has also decided to cross-cut from the 650-ft. point of the Belinda and the 550 of the Calumet, for the purpose of ascertaining the character of the country between the two shafts. A number of Butte mining men have examined the find in the Colleen Bawn and pronounced it identical in character with that found in some of the large copper mines of the district. The vein at 300 ft. is of about the size usual at that depth in Butte.

In addition to running the long cross-cuts from the

Jessie to the Berlin claims, the North Butte has decided to sink a shaft on the Berlin claim itself. It had been the original intention to work the Berlin claims, in the event of copper ore being found, through the old shaft on the Speculator, through which all the North Butte ore is hoisted, but it has been found that that shaft will not be large enough to permit of a much greater output than the North Butte mines are now yielding. The company wants to add considerably to its production and another working shaft is necessary. Two cross-cuts are now heading from the Jessie workings toward the Berlin ground and they will connect with the proposed shaft. There is a two-compartment shaft on the Berlin 350 ft. deep; this will be enlarged and then sunk to a depth of 1,000 ft. at least. The North Butte mines have underground connections with the High Ore mine of the Anaconda Co. and connections are also being made with the Bell and Diamond mines of the same company.

Salt Lake City, Utah.

A New Smelting Company.—Exploration of the Frisco Contact.—Several Mining Deals.—The Yerington Ironsides Co.—The Ontario Adit.—Increase of Wages at Bingham.—Tintic Shipments.—The Coal-Land Investigation.

The articles of incorporation of the Tintic Smelting Co. have been prepared and will be filed within the next few days. This concern will be closely allied to the Utah Smelting Co., which has just begun the operation of a copper smelter near Ogden. Charles W. Nibley of Salt Lake will be president and Bela Kadish manager. The Tintic plant will be built with capacity for the treatment of 400 tons of lead ore daily. The site has been selected near Eureka, in the Tintic mining district. Several prominent Utah mine operators are large shareholders in the company, which appears to have the strongest kind of backing. The headquarters of the new company will be at Salt Lake.

The Talisman Mining Co., operating in Beaver county, has ordered a large mine hoist.—A vigorous campaign of exploration is in progress at the Frisco Contact property, where a drift is being run in a large body of low-grade copper ore. At the Lulu mine, in the same vicinity, a cross-cut is being run to connect with the Horn Silver mine workings as a means of perfecting the ventilation as well as safety. D. P. Rohlfing of Salt Lake is manager of both properties.—The Blue Bird group of copper claims, consisting of 300 acres of patented ground, has been optioned to G. D. B. Turner of Salt Lake, who is preparing to re-organize the company.—The Sidewinder Mining Co., with property in Stateline, has bonded its holdings to W. H. Bramel of Salt Lake and associates.

Articles of incorporation of the Yerington Ironsides Mining Co. have been filed here. The company will operate in the Yerington district of Nevada. A. Hanauer, Jr., is president; W. H. Tibballs, vice-president, and J. H. Turner, secretary. All are of Salt Lake.—The Ely Mining & Milling Co., which recently sold its property at Ely, Nev., to Salt Lake parties, has wound up its business and the proceeds from the sale have been divided among shareholders. The property formerly operated by this Ely company now belongs to the McDonald Ely Copper Co.

C. L. Rood, manager for the Ontario Silver Mining Co., at Park City, reports that the cross-cut run from the parallel drift has been cut into the main tunnel and that the avenue of timbers which have presumably drifted in from the mine are being taken out. Apparently, the last cave has been passed and the main avenue will be cleared without serious difficulty. With this accomplished, deep mining will be resumed in the mines that

have been flooded by reason of the stoppage of the adit for the past eighteen or twenty months.

The managers of the principal mines in Bingham, as well as the management of the Cactus copper mine in Beaver county, have voluntarily granted an increase of 25c. per day to their employees. The raise is to remain effective as long as copper sells at 18c. per pound or better.

Final payments have been made on the options held by Salt Lake and Boston parties on the property of the Bingham Copper Hill Mining Co., in Bingham. The group consists of 115 acres of ground which will be vigorously developed.—The Emma Copper Co., operating the old Emma mine at Alta, is driving several drifts from the Flagstaff tunnel. Some shipping ore has been found.

The ore shipments from the Tintic mining district last week amounted to 125 carloads, the contributing mines and amounts being: Centennial Eureka, 34; Eagle & Blue Bell, 10; Beck Tunnel, 9; Eureka Hill, 9; May Day, 2; Yankee Con., 2; Bullion Beck, 8; Victoria, 6; Grand Central, 3; Mammoth, 10; Carisa, 5; Ajax, 2; Gemini, 5; Scranton, 7; Tintic Iron, 8; Ridge & Valley, 2; miscellaneous, 3 carloads.—The second sitting in this city of the Interstate Commerce Commission to investigate the alleged coal-land frauds in this State and Wyoming has been concluded and resulted in bringing out much sensational evidence and placing some of the officers and agents of the Utah Fuel and Union Pacific Coal companies in a bad light. It is not improbable that criminal prosecutions will follow, in addition to the Government regaining title to valuable coal-lands.

Bisbee, Arizona.

Copper Production.—Important Discoveries in Three Mines.—Calumet & Arizona.—Superior & Pittsburgh.—The Cochise.—Enlarged Output From the Shattuck-Arizona.—Other Mining News.

It is understood from reliable authority that the production of copper at the Copper Queen and Calumet & Arizona smelters will be in the neighborhood of 13,000,000 lb. although the official figures cannot be obtained as yet. A little more than 1,000,000 lb. above the total is credited to the Shattuck-Arizona Co. The feature of the past week has been the discovery of ore in three of the local properties at places where such a development was unexpected. The largest strike of the three was in the Irish Mag shaft of the Calumet & Arizona on the 1,150-ft. level. The drift on this level was being driven in the direction of the Oliver shaft, owned by the same company, when a round of shots opened the full face of the drift into a body of oxide ore. Since the find was made, exploration work to determine its size has been going on steadily, but the proportions of the body have not as yet been determined. The new ore runs a little less than 9% copper.

The second strike was made in the Junction shaft of the Superior & Pittsburgh Co., and has added another producing shaft to the already large list of this company. Work was being prosecuted on the 1,100 level to make connection with the Briggs shaft, which lies southeast of the Junction, when the ore was broken into. It runs about 7% copper, and although the management will not state what the dimensions of the orebody are, it is understood from reliable authority that it is extensive. This is the first orebody of any size that has been encountered in the Junction, and the management feels that it will only be a short time before this shaft completely justifies the confidence which has been placed in it. The Briggs is the only shaft being operated by the Superior & Pittsburgh Co. in which a large orebody has not been encountered,

but as the strikes of the past week are in very close proximity to this section, this shaft is liable to enter the producing class at any time. The third strike of the week was on the Cochise property, which lies north of what has been termed the Dividend Fault, and in a section of the district where heretofore recognized experts have said no ore would be found. On Thursday night the Cochise shaft was sunk into black sulphide, the exact value of which cannot be stated at the present time, but it is understood to be high. It is impossible as yet to say what the extent of this body is, as the exploration work has not progressed far enough. In this same shaft early

in the week a large body of low-grade ore was encountered in the drift on the 300-ft. level. The drift has been driven 48 ft. in the ore, and a cross-cut of 24 ft. has failed to show its full width.

At the Shattuck-Arizona, ore shipments have been averaging 300 tons daily, and it is stated, on the authority of the manager, that this schedule will be greatly increased before the end of the year. The new Allis-Chalmers hoist has been in operation for the past two weeks, and has given entire satisfaction. All of the shipping ore from this property is being taken from the 700 and 800 levels. On the 700 the two oxide and two sulphide orebodies are being stoped, and exploration work is being pushed forward. On the 800 three sulphide and two oxide bodies are being opened up, and the raises from this level to the 700 are both in high-grade sulphide ore. Sinking of the shaft was resumed within the past week, and on Wednesday was driven into low-grade sulphide ore. The new office building to replace the one which was destroyed by fire, is now in course of erection. Martin Pattison, one of the heaviest

stockholders in the Shattuck and Denn-Arizona properties, has been in the city during the past week on a trip of inspection, and before leaving for home stated that he was highly pleased with developments in both properties. It is understood that Pattison, Louis Hill, Guthrie, Barden, Chisholm, Williams, and H. V. Winchell, the noted geologist, all stockholders and directors of the Shattuck, will arrive in this city about December 16, and a stockholders' meeting will be held to settle the matter of constructing a smelter for this property. It is stated on the best authority that the construction of a smelter by the Shattuck people is settled, the only matter being left to decide is the question of time. Rumors have gone the rounds to the effect that a smelter would not be built until the Denn had been developed, but these rumors are based entirely on speculation.

At the Denn-Arizona development work is being carried forward, but there has not been anything of note. Sinking of the shaft is still going on, the depth now attained being 1,075 ft. A station will be cut at the 1,100-ft., and then the work will be resumed until the 1,200 mark is reached. — At the Butte & Arizona property, in the Huachuca Mtn., there have been no new developments, the work being prosecuted along the contact. Plans have been formulated for the more extensive development of this property, but have not been made public as yet. At the Princeton property, in the same district, development work is being prosecuted, and some new machinery has been installed. — Reports from Tombstone are to the effect that everything is about the same as usual.

Cripple Creek, Colorado.

Big Output From the Work Leases.—Elkton Doing Better.—Explorations in the C. O. D.—Shipments From the Index.—Another Leasing Company.—Last Chance to be Worked.—Granite Pays a Dividend.—Lots of Interesting News.

During the period from November 10th to the 20th there were shipped by the Work Co.'s lessees ore that gave returns of over \$68,000. Of this the Work Co. received over \$11,000 in royalties, the balance being paid to the lessees. It is stated that an extra dividend will be declared in December, as well as the regular quarterly dividend in January of one cent per share. — A statement has recently been issued by the Elkton Gold Mining Co. for the three months ending October 31. The gross production for that period was approximately \$191,000 and an average of 1,150 tons was shipped per month, giving a gross value per ton of around \$55. During the above period the stock has risen from 47 to 58c., about 27%. — The suit brought some months ago by E. J. Knight against F. R. Marsh for a $1\frac{1}{2}$ interest in the famous lease of Marsh, Hodges & Co. on the Little Clara claim of the Work Co. has been decided in the District Court of El Paso county in favor of the defendant. The evidence goes to show that Knight did not lay claim to the interest in dispute until after the finding of the rich ore. The case involves the disposition of several hundred thousand dollars.

Ore is again being broken on the large vein encountered a few months ago at a depth of 440 ft. on the Arapahoe claim of the Jerry Johnson property on Ironclad hill. About 200 tons of ore giving returns of a little better than an ounce had been shipped from this depth, it then being decided to sink another 140 ft. and cross-cut for the vein at this lower level. It has been found that the vein where cut is not in pay, so that operations are again being conducted above. Frank Caley has this ground under lease from the Jerry Johnson Co. Connections were made at the lower level with the workings of the Forest Queen, producing good ventilation in both of these

properties. — Work has been resumed by Clint Tillery and partners on the 800-ft. level of the C. O. D. property in Poverty gulch. It is proposed to cross-cut at this depth for the Gold King vein, it being estimated that about 100 ft. will have to be driven for this purpose. — Some rich ore has been obtained on the 700-ft. level of the Matoa property of the Stratton Estate on Gold hill. A streak in a winze has given assays as high as 10 oz. per ton. Reiton & Warmouth, lessees, have endeavored to locate this ore from below, but up to the present they have been unsuccessful. The ore as broken gives returns when shipped of \$40 per ton.

Shipments continue to be made from the orebody recently discovered in the Index mine on Gold hill. The Aetna Leasing & Development Co. is operating this property under the management of William Foley. A car of ore was shipped to Pueblo this week, from which returns of several ounces per ton are expected. The ore is obtained at a depth of 360 ft. A similar orebody is being opened up in the Pointer Mining & Milling Co.'s property adjoining, which is thought to be an extension of that in the Index claim. Small shipments of high-grade ore have been made at times from a depth of 550 ft., but the above company, which has only been organized lately, will undertake extensive work to develop the property more thoroughly. — A leasing company has been formed to operate the old workings of the Jennie Sample mine, on Raven hill; A. E. Carlton and S. S. Bernard are at the head of the enterprise and work will be commenced at once in the 300-ft. shaft. Some good strikes have been made during the year in the Ophir and other mines in the neighborhood and promising results are expected from this leasing company.

The work of preparing the Trilby mine, on Bull hill, for active development has begun and will take about a month. James C. Stewart is general manager. This mine was purchased by a Pittsburg syndicate from the Moose Co. two weeks ago.

The Mobile Gold Mining Co., owning the Last Chance claim on the northeast slope of Gold hill, has leased it to W. A. Riley of Anaconda. This property has been idle for the last five years. Work will be commenced at once, a favorable flat royalty of 20% having been obtained from the above company by the lessees. Extensive development will be done and it is expected that some of the rich veins being worked in the Little Clara, Dolly Varden, and Colorado Boss No. 1 claims adjoining will be encountered. — The Anaconda cyanide mill, situated on the south slope of Gold hill, is running to its full capacity. Low-grade ore is being treated from the South Clara D. workings of the Lexington Co., operated by the Union Leasing Co., and also dump ore of the Lexington Co., together with other custom ore from small shippers. Arrangements are being considered for increasing the capacity of the mill, which is now 60 tons per day. The cold weather experienced lately has interfered with operations, causing the freezing up of tanks and pipes. — J. W. Dunston and associates have obtained a lease on the Alsa R. claim on Raven hill. This property is owned by the Golden Dale M. & M. Co., and is intersected by the Moose Co.'s property which cuts right across the Alsa R. claim. Work has already been started in the main tunnel by the lessees.

The ninth dividend to be paid by the Granite Gold Mining Co. this year has just been declared, amounting to \$50,000 at the rate of four cents per share. This brings the total dividends for this year to date up to \$150,000. Preceding the drowning out of the 10th level, this mine was shipping around 100 cars per month. During the month of November 39 cars were shipped from the Gold Coin shaft and 24 from the Granite shaft. The ore averages about \$35 per ton.

Mining Summary.

ARIZONA.

GRAHAM COUNTY.

(Special Correspondence).—The Gold Belt Development Co. recently cut a wide streak of free-milling ore in their mine near Morenci which assays from \$40 to \$90 per ton. On this same lode at some distance to the east, they have a shaft down 40 ft. and the ore in the bottom averages two ounces gold. Another strike in the properties of this company which has attracted attention is that of a body of manganese-copper ore which is now being exploited, giving a general average of about 30%. Several tons of this ore are being taken out daily in development work, but as yet the extent of the orebody is uncertain. The existence of this body of ore has long been known to prospectors, who were under the impression that the manganese did not carry copper in paying quantities. This ore will be shipped to the Shannon smelter as soon as the road can be put in shape. The company's new hoisting plant is in commission, and the work of sinking the main shaft progressing.—H. H. Harvey has closed a deal by which he disposed of the Pinal Mtn. group, comprising six claims situated about seven miles from Globe. The purchasers are Messrs. Davis & Howard, employees of the Old Dominion Co. The consideration is \$75,000. Considerable development work has been done on the group.

Phoenix, Dec. 1.

CALIFORNIA.

INYO COUNTY.

(Special Correspondence).—John Salesberry, of Tonopah, Nev., has purchased the Sanger copper mine in the Ube-trebe district, and has a large force of men at work. J. V. McConnell, the engineer in charge, reports that the property is looking better as work progresses. There are 14 claims in the group, which have been cross-cut in numerous places on the surface, showing the orebodies to be from 75 to 300 ft. wide. The work at present has been confined to sinking two shafts which have reached a depth of 80 and 90 ft. respectively. The ore is principally carbonate and native copper, and averages from 4½ to 7%. It is the intention of the new owner to continue sinking to the 500-ft. level. There are several other companies in the district that report excellent showings from their properties.

Big Pine, Nov. 24.

NEVADA COUNTY.

Work is being rushed on the property of the Consolidated Willow Creek Co., a bedrock tunnel being run at the Horse Valley gravel mine, 2½ miles northwest of Camptonville. The tunnel is now in 400 ft., and has 140 ft. yet to go. Additional compressors have been requisitioned, but on account of the flint-like rock encountered it will be sixty days before hydraulicking will begin. This property has yielded large returns in the past, although on account of its situation it could not be worked to a lower point than 15 ft. above bedrock. With the completion of the tunnel now in course of construction, the company will have an outlet so that it can wash the bottom strata which carries the bulk of the gold, as well as the coarsest.

SIERRA COUNTY.

A run of 1,500 lb. of ore from the Tightner mine at Alleghany recently resulted in \$90,000 in gold, an average of \$60 per pound. This mine was bonded not long ago to a San Francisco syndicate, but the corporation allowed its option to lapse, and the original owners have started working the property again with the above results.—News of a rich gold strike on the top of Pilot Peak, one of the high natural landmarks of the Sierra Nevadas, has reached Gibsonville. The lode outcrops on the peak, and carries free gold and gold-bearing sulphurets. The claim is owned by Plumas Turner and brother, of Eclipse.

SISKIYOU COUNTY.

Henry E. Wood and H. V. Hodges, of Denver, have purchased a half interest in the Advance mine, near Etna. The price has not been made public. The last crushing of 180 tons averaged over \$30 per ton. Returns from 50 lb. expressed to Denver of specimen ore brought in \$60 per

pound. There is over \$200,000 in sight in the stopes, and the face of the lode is now seven feet wide, the ore from which in the last run went over \$30 per ton.

TUOLUMNE COUNTY.

(Special Correspondence).—The Mt. Jefferson, situated in the township of Groveland, will probably be in operation again soon. The officers of the company are expected to arrive from the East shortly to inspect the property with a view to re-starting work. Should it be decided to resume operations, now that water is available, an air-compressor will be installed to run the mill and hoist.—The collar of the shaft of the Mazeppa mine, at which work was started up several days ago, has been repaired and unwatering will begin as soon as a pump is installed.—Owing to the fuel-oil supply giving out the Harvard mine has been temporarily closed down. The Jumper mill stamps have also stopped working for the same reason. It will be at least two weeks before fuel of the right description is available.—Amended articles of incorporation of the Rawhide Gold Mining Company, filed in this county last week, show that in 1892 the capital stock was reduced from 100,000 shares to 15,000 shares at \$1 each.—Lester R. Wiley, manager for the Big Creek Gold Mining Co., left this week for Bangor, Me., to attend a meeting of the stockholders. He will submit plans for at least one large electric power plant for construction on the Tuolumne river about nine miles from Groveland. Surveys for several sites have been made, one giving the water a vertical fall of 1,973 ft. It is estimated that 20,000 h.p. can be developed, which, according to present intentions, will be transmitted to coast cities. The company owns the Golden Rock ditch, which was recently re-constructed and which supplies the Groveland and Big Oak Flat sections.—E. P. Butts has been appointed superintendent of the Patterson mine, vice J. G. Davies, resigned.—A five-stamp mill will be erected on the Ellen Winton mine, situated south of Tuolumne, the machinery for which has been purchased.

Tuolumne, Dec. 4.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Linn Con. Co., operating the Mineral Chief and Smith & Wesson group on Democrat Mtn., has erected a small mill at the mine with a daily capacity of 10 tons. A wire-rope tramway 1,500 ft. long is being built to the valley below, to which a spur from the C. & S. R. R. can be run at low cost, reducing the expense of handling the concentrate to a minimum.—The Moline adit is being driven ahead and a raise will be put through to the adit above. The mine has steadily developed for the last three years, and large bodies of lead ore have been opened up in all the six adits. Should the present experimental mill prove efficient, the erection of a large mill at the foot of the mountain will follow.—In the Tobin mine of the Waldorf Co., 18 in. to two feet of lead-copper ore has been opened on the Independence lode, which assays \$150 per ton. In the raise on this vein a fine body of lead-zinc ore is exposed. Improvement in the quality of ore in the Kitty Ousley mine of the same company is reported.—The Griffith Mines Co. is now sinking the shaft from its lowest adit on a 30-in. vein of ore which assays \$300 per ton; a small streak running through the lode assays 4½ oz. gold and 9,841 oz. silver per ton with 30% copper. The company's mill is nearing completion and should be running by the first of the year with a capacity of 50 tons daily. Large bodies of ore worth \$20 per ton which have been standing untouched at the mine for many years will then be handled. W. A. Hoover, of Denver, is superintendent.—H. Butts, manager for the Silver Plume Co. operating the Aspen Promise group on Leavenworth Mtn., reports that the ore in the main adit is becoming more solid. The lower adit will be driven ahead 200 ft. to catch this ore.

Georgetown, Nov. 30.

HINSDALE COUNTY.

The Hidden Treasure mine has again started operations, after several months shutdown, on account of the damage to their plant and property by the breaking of the Ute & Ulay dam.

SAN JUAN COUNTY.

(Special Correspondence).—C. W. MacArthur, who has constructed the Gold Prince mill, has finished his contract and left for Denver. This mill was expected to be in operation some time last December or January, but, on account of the railroad to Silverton being unable to move the material for the mill and the early snow, they were obliged to abandon work for the winter. According to Mr. MacArthur, the mill is now completed, awaiting power, which will be secured from the Animas Power Co., whose station is near Rockwood. Some time during September, a large amount of pipe of the power company was washed out and they have not entirely recovered from the damage done at that time. It is hoped within a few weeks to be in a position to furnish power as before. This mill will have a daily capacity of 500 tons and is considered one of the finest in this part of the State. The foundations are of concrete and the frame is made of steel. An aerial tramway connects the mine with the mill. The machinery was furnished by the Denver Engineering Works Co., of Denver. W. Z. Kinney, who has charge of the Gold King property, will also manage the Gold Prince.

Silverton, Nov. 21.

IDAHO.

SHOSHONE COUNTY.

The cross-cut from the shaft on the Douglas mine on Pine creek, south of Wardner, has broken into a solid body of sulphide ore of the same character as that opened for a length of 600 ft. in the upper tunnel. The control of the property is under bond to the Federal company, which has equipped the mine with machinery and is doing the present development work.—Control of the Idaho Giant property south of Mullan has been formally turned over to T. L. Greenough by D. K. McDonald, president of the company. The company is capitalized for 1,000,000 shares at \$1 per share. The price paid was not less than 10 cents per share. The mine will be worked through the Central, a property recently purchased by Mr. Greenough for \$30,000.—Rich carbonate and crystalized lead has been found in the old shaft from No. 2 tunnel in the Idora mine, on Sunset peak. The Idora was examined by R. S. Marian of Wallace, who advised the unwatering of the old shaft, and this will be done.—J. F. Reddy has secured a \$250,000 bond on the Amazon-Manhattan group of mines controlled by the Barry Hillard estate. His associates are M. J. Sweeney and H. R. Allen.—Control of the North Franklin mine, near Mullan, formerly owned by Joseph Peeper, president, Walter J. Bracking, and Norman Ebbley, was transferred to C. F. Booth, acting for a syndicate of Butte mining men. The basis of the sale was 25 cents per share.

NEVADA.

ESMERALDA COUNTY.

(Special Correspondence).—The visit of the Shriners recently and the special train of visitors from San Francisco yesterday have brought this camp closely into touch with the business of the Bay. About 70 San Franciscans came and were shown the bonanza wonders of the camp.

Freight shipments continue to be delayed, due, according to the railroads, to the lack of coal to operate trains. Side tracks are crowded all along the lines with freight for Goldfield, and there seems to be no immediate relief in sight. The volume of traffic headed this way warrants better service.

This week a special train arrived, running as No. 2 of the Overland Limited and carrying a 50-h.p. electric hoist and eight drills and compressor for the Loftus Davis lease on the Combination Fraction ground. The recent strike on this lease has developed into a big body of bonanza ore rich enough to warrant such an expenditure. This vein is a continuation of the famous orebody of the Hayes Monette and Francis Mohawk leases, on the Mohawk, and bids fair to equal it in spectacular values.

The Francis Mohawk lease is operating four shifts of six hours each at \$5 per shift. Their lease expires the first of the year and every effort is being made to extract a full amount of ore. An illustration of their need of haste and the ineffectiveness of the railroad to meet conditions is the big dumps of ore this lease has accumulated, all of which

will run into hundreds of dollars. Being unable to get cars, they pile up bonanza ore.

The consolidation of mines being engineered by Wingfield and Nixon is reported to have bought the Combination. This is one of the oldest and best equipped mines of the district and has paid regular dividends for several years. The reported price is \$4,000,000.

The reports circulated in Eastern papers of the high death rate and the extreme difficulties of living in this camp are grossly exaggerated. The town is always crowded but new hotels are being rushed to completion and in the meantime every one finds accommodation somewhere.

A big rush of people and money into this camp is to be expected as soon as it becomes generally known that good ore is not confined to the Mohawk, and that one does not sign a death warrant by an entrance into this camp.

Goldfield, Dec. 3.

The official statement of the Mohawk properties, merged on November 20 as the Goldfield Consolidated Co., has been issued and shows that previous to the date mentioned the properties included in these interests produced a total income of \$1,172,327. The average freight and treatment rate on ores shipped to smelters for the year has been \$23.50 per ton with 97% extraction. Cost of treatment of oxidized ores in the Combination mill for the same period has been \$5.82 per ton with 91% extraction. The prevailing country rock in the territory controlled by the company is dacite, an eruptive porphyry. In the Mohawk No. 2, bonanza ores have been found continuously from the south end-line northward for a distance of nearly 600 ft. along the claim. Deeper work in sinking the main Mohawk shaft during the past month and the Loftus-Davis shaft on the Combination Fraction have disclosed ore lying at a depth of 300 and 430 ft. respectively, showing no oxidation, and passing through a vein in the former case 35 ft. wide assaying \$50 per ton, and in the latter cutting a vein 10 ft. wide which gives returns of approximately \$100 per ton. The ore in each instance is quartz heavily charged with sulphides of iron, copper, and bismuth. The Consolidated Co. secured an option on property of the Combination Mines Co., comprising 200 acres of valuable ground some weeks ago, and a deal was closed Dec. 1, by which the Combination properties are absorbed by the Consolidated, the consideration being stated at \$4,000,000. This makes the fifth in the group which now consists of Mohawk, Red Top, Jumbo, Laguna, and Combination. The purchase has put an end to the danger of litigation, the apex of the Mohawk and Combination being in dispute.

Articles of incorporation of the Gold Mtn. Carbonate Co. have been filed at Carson with a capitalization of \$1,500,000. J. E. Rickards, ex-Governor of Montana, is president of the new company, whose property consists of five claims, a townsite, and a water right in the Gold Mtn. district. There is a large body of ore on the property and assays have ranged from \$26 to \$82 per ton in gold and silver. The ore is free-milling. A portion of the claims will be leased to prospectors, while extensive development work will be pushed on the remainder.—A rich strike has been made recently on the Olga copper mine situated west of Mina. A large force of men is now at work uncovering an orebody that has assayed 41% copper in the bottom of the shaft. The mine is a short distance from the Sodaville-Tonopah and the Blue Light properties, the vein recently uncovered being an extension of the orebody of the Blue Light. A winze is to be sunk on the 60-ft. level of the Olga and driving started.—The Excelsior Mtn. Copper Co. is pushing work on its 14 claims situated 16 miles southeast of Hawthorne, and about 15 miles from Sodaville. Mineral indications extend for about 9,000 ft. along the strike of the contact, the company having sunk about a dozen pits all in ore. Assays of 18 samples give 8% copper, \$8 in gold, and \$6 in silver. Arrangements are being made in San Francisco for machinery, it being proposed to buy an air-compressor plant with eight drills. Work has been retarded owing to the scarcity of miners.

HUMBOLDT COUNTY.

There is a mining excitement 35 miles west of Humboldt and 30 miles from Mill City. About 250 people have

congregated and the townsite has been named Powhattan. The veins carry rich silver ore, in a porphyry. The most promising claim is in the Rosebud, on which about 30 ft. of sinking has been done.

LINCOLN COUNTY.

(Special Correspondence).—Col. C. A. Hopkins, of Boston, principal owner of the Quartette mine, returned from Los Angeles last week, where he obtained estimates for a cyanide plant to handle the tailing which has been accumulating at the mine for some years, and it is the intention of the owners to put in this plant at once, and also make other improvements. Recently, on the 800-ft. level they struck ore averaging \$150 per ton.—The Barnwell and Searchlight branch of the Santa Fe railroad will soon be built into camp. It is believed that distillate, which is used extensively here for fuel and costs 16½c. per gal. laid down in Searchlight, can be procured when the road reaches here for 6½ cents; and timber which now costs \$50 per thousand for at least \$20 less. This means that thousands of tons of low-grade ore in the Quartette and other large mines running from \$6 to \$10 per ton and costing in the neighborhood of \$6 per ton to mine and mill, with the advent of the railroad can be handled at a profit. The mines in operation at present are milling high-grade ore and a reduction of freight on lumber, fuel, machinery, and supplies will enable many properties with plenty of low-grade ore to run at a profit.—A. A. McKnight of the American Mines & Securities Co. who owns the Fortuna mine at El Dorado cañon, reports they have twenty-five tons of silver ore ready for shipment to the Selby smelter at San Francisco. The owners are considering two propositions in reference to handling their output, whether to install a mill or to build flat boats and transport the ore to the smelters at Needles on the Colorado river. The river is navigable between these points almost the entire year round. They have two shafts down 50 ft., assays running on an average of \$150.—Charles Gracey, who has charge of the Morton property, has gone to Los Angeles to purchase a new equipment for the Tchaticup mine. The shaft is now down 600 ft. The plans of the owners include further sinking and driving. They are putting in a larger air-pipe and have new machinery ordered and already have a 25-stamp mill on the Colorado river about five miles distant.

Searchlight, Nov. 30.

NYE COUNTY.

(Special Correspondence).—The old Chispa mine, now known as the Congress, will soon be re-opened and Supt. Fairchild is now on the ground gathering men for a crew. The main shaft of this company is now down 350 ft. in good milling ore.—A syndicate of California bankers has purchased the Rainbow mines and a shaft will be sunk 1,000 ft. The Mae mine, the Boone mine, and the Boston Johnnie group have been purchased by a company that intends to organize a corporation for the purpose of development.—The Frost and Bowler leases were bought and will be consolidated in a leasing and milling corporation. The Johnnie Wonder Mining Co. has purchased the Iron King and Wonder Fraction claims. The working force on this property will be increased on the first of December.—The first carload of lumber for the new mill has just arrived and construction work will be commenced immediately.—Copper excitement continues and it was further stimulated by the discovery of chalcopyrite in the southwestern portion of the district by J. M. Todd. This prospector also opened up a vein continuing seams of chloride of silver and red oxide of copper.—Coe and Hastings, who have gone to the extreme southwest, have brought in good ore in porphyry. So far they are the first to report this eruptive rock in that part of the Johnnie district. In the Johnnie Con., the drift from the 700-ft. level is being advanced in ore that averages \$24. The drifts on the 500 and 600 levels are in good milling ore. The main shaft is being driven through a vein that opens occasionally to 15 ft. wide and averages \$13.—In the Globe Johnnie the shaft is down 45 ft. in milling ore from the surface to the bottom. The lower tunnel has been forced through the step-fault recently and is now extended 110 ft. The west drift from the main shaft in the Bullfrog Johnnie is being worked in ore, some of which will bear the expense of

shipping. On the Pittsburgh Johnnie a good orebody was opened up on the Lacelle claim.

Johnnie, Nov. 21.

(Special Correspondence).—One of the newest mining flotations put out of Goldfield within the past month is that of the Keane Wonder Mining Co. of South Bullfrog. This company owns 22 claims on the Death Valley Slope of Funeral Range, 12 miles south of Rhyolite. Six or seven well-defined lodes traverse the company's holdings, and good values have been obtained from selected samples. One vein is in the neighborhood of 30 ft. wide, containing solid quartz with good walls, the vein averaging \$18.10 per ton in gold. Three adits, one above the other, have been driven into the hill and the vein encountered, with the result that \$650,000 of ore has been blocked out. A new adit has just been started at the base of the hill, which will tap the vein within a short distance, and give the company over 1,000 ft. of backs. A 20-stamp mill, with 1,200 lb. rapid drop stamps, is now under course of construction and will be in operation within 90 days. The mill is being furnished by the Risdon Iron Works of San Francisco, and will be complete in every detail, with facilities for concentration, amalgamation, and cyaniding. From tests made, 90% of the ore will be saved. A Riblet aerial tram will carry the ore from mine to mill, and within 90 days' time the Keane Wonder Mining Co. will have one of the best mine equipments in the State.

Goldfield, Dec. 1.

SOUTH DAKOTA.

CUSTER COUNTY.

(Special Correspondence).—The Southern Black Hills are enjoying a revival of mining activity and development work. The Granite Reef group, situated about two miles southeast from Custer, was sold last week to R. G. Galespie, of Pittsburg, Pa., for \$20,000, a cash payment of \$1,000 having been made, the balance payable in four months. The former owners were C. W. Robbins, Jas. Demerau, and A. T. Feay, all of Custer, the property consisting of ten full claims and two fractions. Mr. Galespie is owner of a number of wells in different oil districts, and has appointed Dan McGanagal as his local agent.—Mining for mica is on the increase in this county, and two sales of this description of property took place within the last fortnight, the Westinghouse E. & M. Co. being the purchaser in both instances. One of these mines, known as the White Spar, was owned by W. W. Olds, of Custer, while the other, situated about four miles west of the city, was the property of J. L. McKenna. Both were cash transactions, but the consideration has not been made public.—Among the varied mineral resources of Custer are veins of lithia-bearing ore, and two of these are being worked at the present time, R. Bond shipping ambligonite from his mine near this city on a contract at \$25 per ton f. o. b. at Custer. Chas. Meigs, of New Jersey, is buying the material and sending it to his home town for treatment. The consumption of lithia is said to be largely on the increase in this and other countries, and its production bids fair to become one of the important industries of this county.—The Newark group of gold mines, numbering 21 claims, including the Turk group and a placer location of 80 acres, with water rights on French creek and Crow creek, are under bond to Eastern parties, who are expected to arrive and close the deal in a few days.

Custer, Nov. 27.

UTAH.

The Boston Consolidated Mining Co. has contracted with Fairbanks, Morse & Co. for the purchase of 312 Nissen stamps to be erected at their Garfield plant. Tests with the Nissen stamps showed a crushing capacity of 10½ tons per stamp per 24 hours.

WASHINGTON.

OKANOGAN COUNTY.

Pay-ore has been found in the Capital mine near Twisp, where, in the long tunnel, a body of ore assaying \$69.47 in gold has been opened. When the permanency of the ore-shoot has been demonstrated, a mill will be built. At the Red Shirt mine, an adjoining property, more than 3,000 ft. of work has been done. The owners are arranging for additional machinery.

Personal.

H. A. TITCOMB is at St. Petersburg.

GEORGE H. EVANS is examining mines in Nevada.

H. A. KELLER has returned to New York from Alaska.

ROSS E. BROWNE has returned from London to San Francisco.

WM. L. COBB has been examining mines at Rhyolite, Nevada.

G. A. DENNY, lately at Johannesburg, is visiting Denver and Leadville.

JOHN E. ROTHWELL, of Denver, is engaged in professional work in Mexico.

CARL HOFFMAN has returned to San Francisco from Guanajuato, Mexico.

FRANK H. PROBERT is examining mines in the Tonopah and Goldfield districts of Nevada.

HOWARD D. SMITH has returned from the examination of mines near Jefferson City, Nevada.

CYRUS ROBINSON is now consulting engineer to the Balbach Smelting & Refining Company.

FREDERICK A. GOWING has returned from Guadalupe y Calvo, Mexico, and is now at Oakland.

ALGERNON DEL MAR has been appointed mining engineer to the United Cobalt Exploration Company.

CHARLES J. EAMES, JR., is consulting engineer to the Boston-Mexican Mines Co., in Sonora, Mexico.

RICHARD B. STANFORD has resigned as manager of the Siempre Vivre Mining Co., at Bluefields, Nicaragua.

JOHN H. BANKS, of Ricketts & Banks, has been to Cobalt recently in connection with metallurgical problems.

JOHN HAYS HAMMOND and A. C. BEATTY have returned to New York from a visit of inspection at Cobalt, Ontario.

STANLY A. EASTON, manager of the Bunker Hill & Sullivan mines, has been visiting New York on his wedding trip.

C. H. SCHOEMAKER is assistant mining engineer to the Minas Tecolotes y Anexas, at Santa Barbara, Chihuahua, Mexico.

A. F. MAIN, assistant manager to El Oro Mining & Railway Co., has been examining the Rosario mine at Guadalupe y Calvo, Mexico.

JOSEPH GAZZAM, late manager of the Simmer & Jack, at Johannesburg, will be local manager for the Nevada Copper Con. Co., at Ely, Nevada. POPE YEATMAN will be general manager.

Trade Treatises.

THE INGERSOLL-RAND COMPANY, of New York, issues Catalogue X36, being a description of their Imperial Type Ten air-compressors.

THE COLORADO IRON WORKS Co., of Denver, issues Bulletin No. 21, entitled 'Screening and Sizing.' The Impact screen is described in detail, as well as other specialties, such as the Dorr classifier.

THE UNITED STATES DRYING ENGINEERING Co. has sent us their catalogue, containing a description of their automatic machinery for the utilization of by-products. The styles illustrated include direct, indirect, and steam-dryers, and an automatic digester for the conversion of garbage into fertilizing products.

THE B. F. STURTEVANT Co. issue Bulltin 134 of their Engineering series. It illustrates the type of blower manufactured by this firm originally designed for supplying air to cupolas and forges, and now adapted for all purposes where pressure up to 16 oz. per square inch is to be maintained, or where air is to be forced long distances. Methods and appliances for driving these blowers are appended.

Publications Received.

HARRON, RICARD & MCCONE, of San Francisco, have issued a handsome book of views, illustrating the effect of the earthquake-fire, in the expectation within a few years of being able to issue another set of views illustrating wonderful progress in rebuilding.

ZEEHAN SCHOOL OF MINES. Annual Report, 1905. This comes to us from a useful institution on the west coast of Tasmania. It contains a general report on the doings of the School of Mines at Zeehan, a silver-lead district, and special articles on mining and smelting.

REPORT OF THE COMMISSION appointed to investigate the zinc resources of British Columbia and the conditions affecting their exploration. Mines Branch, Department of the Interior, Ottawa, Canada. This is a volume of 400 pages, handsomely illustrated, giving the results of a careful investigation made by Mr. Walter R. Ingalls, editor of *The Engineering & Mining Journal*, New York, and Mr. Philip Argall, mining engineer, Denver. The work was made by the Canadian Government at the instance of the Silver-Lead Association and Associated Boards of Trade of British Columbia. It is certainly one of the best government reports issued during recent years. There is a lot of valuable information on zinc treatment, with description of various machines, and a most excellent account, with detailed drawings, of the geology of the mines.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE cost of candles in ordinary driving underground is about 25c. per linear foot.

AN UNDERGROUND TRACK should always be well graded and equipped with fish-plates. A bad track causes incessant delays, which result in high costs and small output.

WHERE heavy trains have to be taken round sharp curves, the track should always be watered behind the locomotive drivers. This will reduce the tractive force about 100 % in some cases.

THE velocity of a stream may now be measured chemically. By the new method a certain quantity of brine is added to the water, and samples afterward taken at given points further down are analyzed.

SOMETIMES pieces of corundum and sapphires that are valueless as gem-stones, owing to their opacity and bad color, are coated with graphite and sold as carbons for diamond-drills. They accomplish a double fraud, being both heavier and less hard.

DITCHING can be done for 20c. per cu. yd. if a plow and scraper be used. If the soil be so rocky as to call for a pick and shovel, it will cost 40c. A fair price for a ditch 18 in. deep, 3 ft. wide at the bottom, and 4½ ft. wide at the top, is \$3.65 per rod.

A CHARCOAL-IRON BLAST-FURNACE at Gladstone was recently placed in blast after having been banked for 17 months and 12 days. Following this suspension of over 17 months, the drafts were opened and the plant started without re-building the fires or removing the charge.

SLIME is not altogether a matter of extreme fineness, but the manner of its creation is also a factor, since aeration in process of crushing greatly increases the visual evidence of slime. For concentration, therefore, it is plain that aeration of pulp is not desirable.

A 10 % SOLUTION of ferric chloride affords ready means for distinguishing calcite (calcium carbonate) from dolomite (magnesium carbonate). Immersed in this solution a piece of calcite soon becomes coated with a brownish deposit of hydrated ferric chloride. Dolomite does not give this reaction.

IN THE SELECTION of scrap tin for use in copper precipitation vats, care should be taken to avoid lacquered sheets, as they will only be attacked on the exposed edges, and thus their effective surface is much reduced. The use of scrap tin in preference to iron is a great economy; the product is of higher grade and the cost of handling is much less.

THE capacity of round or hexagonal revolving screens or trommels, running at 20 rev. per min. will screen approximately as follows per square foot of screen surface :

8-mesh screen, 100 lb. per hour.			
12	"	"	80
16	"	"	65
20	"	"	50

POWER generated from electricity is usually sold to the metal mines of the West at from 5 to 8 dollars per horse-power per month according to the locality, the distance

of transmission, and the quantity bought. The old contracts still fix the price by the horse-power per month, the consumer paying for a specified amount, whether consumed or not. In the new contracts, it is usual to sell by the kilo-watt hour.

AT Iron Mountain, Mich., at the Hamilton Iron mine a supposedly perpendicular diamond-drill hole 600 ft. deep was bored. Later, a perpendicular shaft was sunk so as to include the drill-hole at the southwest corner at the surface. By the time the shaft had been sunk 400 ft. that particular hole had moved over and disappeared under the north set, to come back again into the shaft, to again disappear in the northeast corner, and, from then on, it was never known what had become of it.

THE capacity of a set of rolls depends largely on its evenness of surface. If the rolls are worn so as to become corrugated, and so that they do not meet except in spots, their efficiency is reduced, often as much as 50 %. A set of well constructed 14 by 27 in. rolls, with even surfaces, and running at 100 rev. (700 ft. peripheral speed) per min., and taking ordinary quartz ore from the crusher at 0.5 in. size; will reduce it approximately as follows:

To pass 8-mesh screen 3,500 to 4,000 lb. per hr.			
"	" 12 "	" 2,500 "	" 3,000 "
"	" 15 "	" 2,000 "	" 2,500 "
"	" 20 "	" 1,500 "	" 1,800 "

ON THE MOTHER LODE, California, the cost of sinking and timbering the ordinary three-compartment shaft averages between \$30 and \$50 per foot. The Gwin shaft to a depth of 1,800 ft. cost about \$40 and the Oneida to the same depth cost \$67 per foot with hand-drilling and under exceptional difficulties. The following were the costs per foot for machine-drilling at the Centre Star mine at Rossland, B. C.:

	Sinking main shaft.	Sinking small shaft.	Raising.	Driving.
Compressed air.	\$3.48	\$3.26	\$3.07	\$1.35
Drill fittings	1.46	1.53	1.83	0.65
Labor	24.70	20.13	16.77	7.25

CHARCOAL is today manufactured in retorts so that the by-products of the wood may also be recovered. The smoke from such retorts is drawn through extensive coils of copper piping surrounded by cold water and forming an immense condenser. By this process the smoke is chilled and reduced to the liquid state carrying a heavy, coffee-colored sediment. The liquid is then put through various processes by which the solids are separated from the fluids and various by-products secured. A cord of maple wood weighing 3,500 lb., will yield 880 lb. or 44 bushels of a dense charcoal, 8 gal. wood tar; 4½ gal. wood alcohol, 208 gal. pyroligneous acid and 64 lb. acetate of lime. The charcoal is used in the blast-furnace work, the acetate of lime in the manufacture of smokeless powder.

THE rocks of the Manhattan district, in Nevada, range in geological age from Algonkian through Cambrian to, probably, Silurian; the eruptives that penetrate them are Tertiary and the gold itself was introduced in, geologically speaking, recent time. There are placers in the soil and surface wash at Manhattan (derived from the rain-erosion and weathering of the veins) in which the gold is ragged and angular—not the least water-worn. "It has all its arms and legs," as the miners say. These placer deposits overlie washed gravels deposited by the post-Neocene erosion of the region; so late has been the introduction of the gold in the veins that primitive man may have been building his fires when the fern-like crystals of gold were forming at Manhattan and Round Mountain.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Prospecting Dredging Ground.

The Editor:

Sir—In your issue of November 3, Mr. D'Arcy Weatherbe attacks the drill method of prospecting dredging properties on two grounds, namely:

- 1st. That it is not so reliable as shaft-sinking.
- 2nd. That it costs more.

Allow me to take exception to these statements. They are not borne out by the experience of men who have tried both methods. I believe we might modestly claim the credit of having, about ten years ago, introduced the present generally followed plan of testing or exploring prospective dredging ground by means of the drill. At that time I was called to Boston to consult with Mr. Charles E. Souther, president of the New England Dredging Co. about a prospect he was trying to make near Boise City, Idaho. He was attempting to do it by shafting and, after spending a small fortune and about a year's time, he had failed to get a single shaft to bedrock. He had been driven out by the water. If I remember correctly, he had sunk two or three shafts in close proximity, using the pump in one to lower the water in the other, but still failed. The inflow of the water carried with it the sand, and even if he had gotten the cribbing to bedrock he would have been wholly uncertain how much of the material excavated belonged to the area of the shaft. We furnished him a machine and in about one month his operator reported having sunk "seventeen holes to bedrock in twenty-four days." Mr. Souther was so well pleased with the results that he enclosed us a check for the price of the machine and ordered a second one shipped to Yreka, California. The machine was sent and its operation introduced to the attention of dredge-men at Oroville. There are now at Oroville more successful dredges than in any other like area in America, and we believe that the ground being worked has in every case been reliably and, as results of dredging show, successfully prospected by duplicates of the original drill furnished to Mr. Souther. If there has ever been a failure of a dredge, which followed prospects accurately made by the drill, we have not heard of it and we are in pretty close touch with every dredging field in the world.

It is practically impossible to sink a shaft, by the China method or any other, through boulders and quicksand, and take out an exact area. The inevitable influx of silt and sand from the surrounding embankment may completely vitiate the test. On the contrary, if carefully done the 7½-in. hardened steel drive-shoe usually cuts an exact area from top to bottom, and the contents of this test-tube may be taken up with exactness and certainty. Of course, some allowance must be made when the ground is entirely composed of large boulders, but even here the chances are in favor of the drill, for it will break a round hole right through them. The presence of water, quicksand, flowing silt, etc., offers no resistance whatsoever, but may and does require a little different method of handling the drill and driving the test-tube.

The question which Mr. Weatherbe raises was brought out and conclusively settled eight or nine years ago at Oroville, by a system of experiments. Drill-holes were first sunk and the values obtained were carefully computed; then, without removing the test-tube, a shaft was sunk around it to bedrock and the values from it likewise accurately computed. The two sets of values were

then compared and my informant stated that the value per surface area of the *shaft* was somewhat the larger, but the dredge afterward proved that the value determined by the drill was nearer correct.

As to the difference in cost of prospecting by these two methods, the question is perhaps an open one. No general conclusion, that will absolutely apply to all localities is possible. Shallow tests in dry clayey ground might in some instances be made by shafts at a lower cost. But in frozen ground, such as is found in Alaska and Siberia, or in submerged quicksand such as is liable to occur anywhere, the cost by the drill method has been proved by hundreds of experiments to be far lower. On one occasion, in Oregon, with the assistance of two men, in a quicksand swamp where water stood within 12 inches of the surface, the writer sunk holes 88 to 91 ft. deep at the rate of one in 16 hours. In average ground it is common to make a 35 to 40 ft. test in 10 to 12 hours with a crew of three men.

But first cost is of little significance. *Accuracy* is the thing that counts. And without going further than the complete and invariable success of the operations at Oroville, the verdict is for the drill method.

R. M. DOWNIE,
Keystone Driller Company.

Beaver Falls, Pa., November 12.

Gold Dredging.

The Editor:

Sir—Referring to Mr. D'Arcy Weatherbe's valuable contribution in your issue of November 3, I may state that the season for dredging in New Zealand has been unfavorable, especially on the Molyneux river and its tributaries. The river has successively fallen and risen in such a way as to cause suspension of work on the dredges in the gorges and a hampering by drift and silt on the others. The season is almost over and only a few days of actual operation have been possible so far this year. Outside of the gorge dredges, there are between 40 and 50 machines at work in Ontago with a total output of about 1,000 oz. of gold per week.

San Francisco, November 7.

Treatment of Copper Ore.

The Editor:

Sir—I am inclined to disagree with an item under the heading of 'Concentrates' in your issue of November 10. A process is described in which copper carbonate ore is treated at the Snowstorm Co.'s mill at Larson, Idaho, by subjecting the crushed ore to the action of a 10% solution of sulphuric acid and a solution of chloride of lime; it is inferred that the latter is added with a view to converting any silver contained in the ore into chloride, thus forming a ready means of separation between insoluble silver chloride and soluble copper sulphate. Now, while chloride of lime would certainly serve this purpose, it is hardly likely that it is added with this end only in view, for a solution of common salt would answer equally well and not only is the latter much cheaper than chloride of lime, but weight for weight it contains considerably more chlorine and therefore a given quantity is capable of converting more silver into chloride than the same quantity of chloride of lime. Without knowing the nature of the ore it is only possible to hazard an opinion, but I am inclined to think that the chloride of lime solution is added with the object of attacking small quantities of copper sulphide or native metal which may be contained in the ore. The chloride of lime coming in contact with the sulphuric acid would give off nascent chlorine which would be capable of attacking both native copper or copper sulphide, while sulphuric acid and salt,

unaccompanied by an oxidizing agent, would have comparatively little action upon either.

It may be that the silver in the ore is in such a state of combination, that while it is not attacked by sulphuric acid, the thiosulphate solution, used to leach the residue insoluble in sulphuric acid, would have no action upon it either. In this case the chloride of lime solution would be used to convert the silver into a form in which it is readily attacked by thiosulphate of soda solutions.

F. H. MASON.

Johnsville, Cal., November 16.

Milling Gold Ores.

The Editor:

Sir—There has been an interesting discussion lately in your journal in relation to 'The Position of Plates in a Mill,' and now comes an article in your last issue by Mr. Algernon Del Mar on 'Milling Gold Ores.' Such discussions are instructive and interesting to me, for they call to mind personal experiences occurring during many years of mining and milling. Being a millman of some experience, I can fully appreciate the article on 'Milling Gold Ores,' yet it appears to be a pretty large dose for the ordinary layman to digest. The article is as full of meat as an egg, and seems to be quite a treatise in a condensed form. Not being in love with inside amalgamation, I do not agree with the writer that "once caught inside the mortar, the gold is as good as coin," because very often the night millman goes to sleep, or there is a sudden change in the richness of the feed, and under such circumstances the amalgam on the inside plates gets too hard and is scoured off, or gets too soft and is sloughed off. The millman knows nothing about it till he examines his outside plates, and how long some plates go without being examined, only the Lord and the millman know; consequently, some of it is lost, for, as your contributor says, "scoured amalgam is difficult to catch on outside plates." I have often seen a thick coating of amalgam on a chuck-block that we were taking so much pains and pride to build up, as only a millman can realize, change color from a silvery white to rusty red or black; then, of course, no further amalgam could be looked for on that plate, and the only thing to do was to change plates in order to save the amalgam.

Mr. Del Mar gives the general impression in his article that inside amalgamation should be commended, and then cites his own experience as otherwise: For instance, he says, "With an ore in Nevada, a 50-mesh screen (which is conducive to inside amalgamation) gave \$12 to \$15 tailing, while a 30-mesh screen (which is less conducive to inside amalgamation) gave only \$6 to \$8 tailing," and he adds that this experience was rather puzzling. I think he has given a good reason for it, and about the only real one, when he says, "Extreme comminution causes flouing of both gold and mercury, which are then most difficult to catch. Extreme comminution would take place with the 50-mesh rather than the 30-mesh screen. Again: "In an experiment with a roller mill crushing dry, mixing with water and running over copper plates, less than 30% of the gold content was caught, while the same ore, after being reduced in a five-stamp battery over the same plates, has yielded over 80%." This experiment shows that dry-crushing allowed the gold content to become foul with air and dirt, which would prevent amalgamation; on the other hand, wet-crushing, which presumably was the case in the five-stamp battery, would protect the gold from being fouled until it came in contact with the mercury. We all know, or ought to, that when mercury is 'floured' or subdivided it is likely to become 'sickened,' that is, coated with a film of air or dirt, so that no amount of agitation will

force the globules of mercury to come together again till it has been thoroughly cleaned. Until then it is of no use as far as catching gold is concerned. The same process applies to gold; it can be crushed so small as to become floured and fouled, and then it is indeed a fight between the millman and the tailing sampler. Quite a number of mills along the Mother Lode of California have in the last few years lowered the discharge, and are using coarser screens, thereby doubling the output in some cases, in the same mill, without a corresponding increase in the value of the tailing.

It does not take much to foul both gold and mercury. Let me cite a personal experience. Some years ago I was sent to South America to take charge of a 20-stamp mill. The mortars were deep and roomy; they contained a back inside plate and a plate on the chuck-block. The outside plates were not silvered, they were the width of the mortars and eight feet long, no other plates or concentrators were used, except a few feet of plate in a launder at the lower end of the mill that apparently were forgotten. The head millman was a white man who was not from California, his help consisted of two or three natives, and the method of saving gold was to soften the plates every morning with mercury rubbed on with the bare hands. The amalgam was left on the plates from one clean-up to another, which was at the end of every month. Sulphides would foul the plates badly, and they were rubbed off with the bare hands about every three hours, with the stamps still dropping and the pulp and water running over the plates. The average saving was 35 per cent. It is needless to say that the natives were at once taught a different method. The discharge was lowered, the inside plates were taken out, as the ore was very low-grade, the screen was changed from 40 to 30-mesh brass wire, the plates were treated in California style, and the value saved was at once raised to 75 per cent. No matter how clean the hands, if they are rubbed hard on the outside of a screen while the mill is running a blotch will appear that looks like grease and for a few seconds will actually prevent the pulp from coming through that part of the screen—if the hands will do that to a screen you can imagine the effect on a sensitive plate.

At another mill in Costa Rica run entirely by natives, I saw them dressing the plates by pouring on mercury by the bottle-full; rubbing it off at the lower end with their hands, and catching the surplus in a launder. I heard afterward that this mine did not pay, but have no doubt that the creek below the mill would pay well. To summarize, every mill as well as every mine, is a problem by itself, and when the right kind of a mill is installed it requires constant attention on the part of the millman to prevent loss of gold. When the millman has time to read newspapers and novels, as some do, then he is in the wrong position. When I visit a mill and hear nuts and washers jingling around the battery-frame, I know that the millman needs 'jacking-up' or sent to the office, for he is not in the right position. He should always be where he can detect the slightest change in the sound of the stamps, see that the screens are discharging freely, the plates in proper condition, etc. His position is just as important as the grade and position of the plates. He should not only be a mechanic and machinist but a metallurgist to the extent of knowing the nature and affinities of gold, silver, copper, mercury, cyanide of potassium, and the different acids. And when the millman puts in 12 hours in a 40-stamp mill or even a small rattle-trap, and does his duty, the nervous strain is almost too much and he should receive better pay than he usually does, for he is the man who can save or lose more money for a company than any other.

H. P. GORDON.

East Oakland, November 24.

West Australian Gold Mining Costs.

Specially contributed to the MINING AND SCIENTIFIC PRESS.

[We owe this valuable paper to the courtesy of the engineers in charge of the important gold mines managed by Bewick, Moreing & Co., in Western Australia. Our thanks are specially due to Mr. H. C. Hoover. The managers of the mines in question are: H. E. Vail, at the Lake View Consols; R. B. Nicolson, at the Ivanhoe; D. P. Mitchell, at the Oroya-Brownhill; John McDermott, at the Sons of Gwalia; J. Allen, at the East Murchison; Gerard Lovell, at the Great Fingall; and C. Hope Nicolson, at the Cosmopolitan.—Editor.]

It is of some interest to have a generalized figure as to working costs in a given region. In South Africa and West Australia the mines are operated in 'groups' under one central head, which results in a similarity of accounts, and in most cases the expenditures are set out fully in annual publications and present an opportunity for collective comparison. The method of combining the costs of a number of mines into one cost sheet, as if it were one mine, is of course open to much objection from the standpoint of detail, yet a generalized figure may be of some interest to your readers, and though the data were prepared for other purposes, they may be worth publication. Seven mines have been chosen from the group of 18 associated with Messrs. Bewick, Moreing & Co., and they were chosen as being representative of the variable conditions of the larger mines as to size, transport character of ore, etc. The mines selected are:

Name.	Stamps.	Locality.	Distance by rail from coast, miles.
Lake View Consols.....	70	Kalgoorlie	390
Ivanhoe.....	100	"	390
Oroya-Brownhill.....	50	"	390
Sons of Gwalia.....	50	Mt. Leonora	490
Cosmopolitan Proprietary.....	50	Kookynie	460
Great Fingall.....	100	Day Dawn	480
East Murchison United.....	40	Lawlers	580*

*In this case it is 490 by rail and 90 miles by wagon-road from the coast.

In dealing with such deposits the difference of economic surroundings in mines a few miles separated, the variability in the size of orebodies in even adjoining mines, or the character of ore and its consequent treatment, lend justifiable cause for wide fluctuation in costs from one mine to another, even in the same district. The Oroya-Brownhill presents one extreme, in that it has the most difficult and complex of telluride ores, and the Cosmopolitan another, having clean quartz easily amenable to amalgamation and concentration with cyanidation of sand, slime, and concentrate. This group of mines employed 420 stamps during 1905, and milled 944,736 tons of ore.

METHOD OF ACCOUNTS.—The expenditures in various departments are split up into Labor & Salaries, Stores, Power, Assaying & Sampling, and Repairs & Maintenance. Obviously, the last three items are composed also of Labor and Stores, and they are first segregated separately and then spread over the various departments, the power according to steam consumed; the Assaying & Sampling as to the origin of the sample; the Repairs & Maintenance according to the locality of the work required.

In dissecting the expenditure, it was found that of the total expenditure 45% was for wages and salaries, 38% for stores, and 17% for sundries, such as insurance, taxes, shipment, and refining of bullion, etc.

Labor.—There were worked upon these mines 678,025 shifts (a maximum of 8 hours), showing the average cost per shift to be 15s. 5.51d. Of the total of £524,085. 3. 9 thus expended upon labor, the various departments bear the following ratio:

	Per cent.
Development.....	24.21
Ore extraction.....	46.63
Ore treatment.....	23.03
General expenses.....	6.13
Total.....	100.00

Stores.—The following table shows the percentage of each to the whole. The total expenditure on stores was £438,121. 6. 5.

Description.	Per cent.
Explosives.....	11.82
Fuel.....	29.69
Steel.....	1.03
Candles.....	1.63
Timber.....	4.38
Cyanide and bromo cyanide.....	13.15
Quicksilver.....	1.25
Mill spares.....	4.32
Sundries.....	3.50
Other supplies.....	27.34
*Water.....	1.89
Total.....	100.00

*This refers to water purchased only, not to water procured by the companies' own plants; nor does it include cost of distillation, all of which are included under Power.

Power.—In power generation 160,974 tons of wood and coal were consumed, and 44,669,167 gal. make-up water were used, 103,263,127 gal. water consumed in condenser cooling, and 13,632 gal. lubricating oil employed. The total amount of steam generated was 1,344,988,900 lb. The efficiency of engines varies greatly, from the triple-expansion condensing engine at 14 lb. per h.p. hr. to the sump-pump at the tailing dam, consuming 60 lb. The total expenditure debited to this department was £185,940. 1. 9, or equal to 3s. 11.27d. per ton of ore treated.

Assaying & Sampling.—The total number of assays made was 188,529; the total expenditure was £12,923. 9. 7, or 1s. 4.45d. per assay. There were 143,286 samples taken underground, at a cost of £5,966. 1. 1, or 10d. per sample.

Repairs & Maintenance.—The total expenditure under this head was £120,562. 6. 0, or a cost per ton of 2s. 6.63d., divided as follows:

	Per cent.
Labor.....	55.55
Supplies.....	42.19
Power.....	1.33
Sundries.....	0.93
Total.....	100.00

As depreciation is not taken into account in this statement, it may be well to note that all construction, except actual extensions, is charged under the above head, and it is expected that for the major part, plants are preserved in the original state of efficiency. As depreciation is really a factor of the life of the mine, and this is unknown, it is the practice in these companies to write off the original construction on their balance sheets, the same year it was installed, so that the plants are not carried as an asset at all. If it be assumed that the life is 12½ years, then the depreciation would be about 8% per annum, or in this case roughly two shillings per ton of ore treated.

EXPENDITURE ON DEPARTMENTAL BASIS.—The organization of any mine may be considered as a chain made up of many links of variable lengths, each representing a special operation. The number of links and the length of the link varies with each mine. To attempt to compare in detail results in even a group which, as the above, is under practically the same administration, would be sufficient warning to all those who love to contrast results upon one mine or another. I believe it to be quite impossible to assign any particular relative value to such links, nor is it possible to assess a value to the causes which create variation in the costs of the same links in various mines.

From the standpoint of costs, the number of links is not so important as the stress that may be laid upon a

particular link. For instance, the Oroya-Brownhill grinds all sand to slime, in order to obtain perfect extraction, while on the Ivanhoe, with an ore of only one-half

The following table gives the details of expenditure, contract work being accounted for as if it were on day's pay :

TABLE I. DEVELOPMENT.

	Shaft-sinking			Driving			Cross-cutting			Rising			Winzing			Diamond-drilling. *			Average cost per foot of all work except diamond-drilling			Cost per ton

* Cost, but not footage, included in totals.

the value, such a course is not economically advisable, and the latter mine profits in costs by the cheaper method of percolation instead of grinding and filter-pressing the whole product. Such differences might be pointed out with regard to every mine, but to describe all those differences would run into a volume of itself and obscure the main objective which is to indicate a sort of mean average of costs.

The links in the chain of operations on these mines are divided as follows, for purposes of this article:

1. DEVELOPMENT :
- a. Shaft sinking.

b. Driving.

c. Cross-cutting.

d. Rising.

e. Winzing.

f. Diamond-drilling.
2. ORE EXTRACTION :
- a. Breaking ore.

b. Supporting stopes.

c. Haulage to surface.
3. TREATMENT :
- a. Rock-breaking.

b. Transport to mill.

c. Stamp-milling.

d. Concentrating.

e. Treatment of concentrate.

f. Fine grinding of sand.

g. Cyanide treatment of sand.

h. Cyanide treatment of slime.

i. Disposal of residue.

j. Precipitation and smelting.
4. ADMINISTRATION :
5. REALIZATION OF BULLION :

DEVELOPMENT.—A total of 48,102 ft. of openings were made, omitting plat-cutting and diamond-drilling. The ore in these mines occurs as orebodies or ore-shoots in quartz lodes, and involves not only a large amount of dead work to reach the ore, but a large amount of purely prospecting work in search of new ore. That this is no inconsiderable item can be surmised from the fact that less than 40% of the total footage done was actually in ore. How far this enters into the question of development costs, as compared to mines with continuity of ore, even much narrower reefs, is indicated by the fact that nine Rand Mine, Ltd., ‘subsidiaries’ are given in 1905 as having done 50,823 ft. development work, resulting in the exposure of 2,599,000 tons ore, or about 51.1 tons per foot, as against an average of 22 tons in this West Australian group; in other words, the narrow reefs of the Rand require less than one-half the amount of development work in order to secure the same tonnage.

The total sum of £217,519. 17. 2 was expended upon development. In the system of accounts followed an amount equal to the cost of stoping the tonnage of actual ore broken in the course of development is deducted from the development charge and added to ore extraction, the remainder being considered *pro tem.* a capital outlay, and is written off either by way of redemption or by direct depreciation in the balance sheet. The net amount charged to Development Account was £199,489. 5. 7, or equal to 4s. 2.67d. per ton, on the 944,736 tons milled during the year. There was, however, actually developed during the year a total of 1,057,751 tons, so that the real cost of development would be, if redemption were done, 3s. 9.26d. per ton, and this figure is used in final summary.

ORE EXTRACTION.—The average stoping width is between seven and eight feet. The length of continuous runs of ore is usually not long, but this is a matter affecting development more largely than actual ore-breaking. A large proportion of the ore is broken with machine-drills. Under colonial law, all stopes must be supported, and as the cost of timber for this purpose is prohibitive, recourse to some method of filling is universally resorted to. The angle of dip varies considerably, and in three mines of the group it is too flat for the ore to ‘run,’ and must be shoveled from the stopes. The total expenditure on this account, including ore from development, was £390,107. 5. 9.

The following table indicates the costs:

TABLE II. ORE EXTRACTION.

TREATMENT.—The basis of treatment is stamp-milling, concentration, and the leaching of various products by cyanide. With this statement similarity ends, as a different amount of fine grinding, percolation, and sliming results on each mine. The costs of treatment on the different mines varies from 8 to 16 shillings, the higher costs being due to special treatment demanded by the

occurrence of rich tellurides in some of the mines. The following table shows the cost in some detail, upon the mill tonnage, and the supplementary tables show the cost of special operations on the tonnage actually handled in these operations:

Hydraulic Mining in Colorado.

Written for the MINING AND SCIENTIFIC PRESS
By W. E. THORNE,

In this article I will endeavor to give some of the actual

ADMINISTRATION & GENERAL.—These items include Superintendence, Taxes (except duty on dividends), Rents, and charges generally not allocatable to special departments. They do not include London Expenses.

The total of these charges was \$75,320. 8. 11, or 1s. 7.13d. per ton, of which £24,678. 5. 0 was for shipment and refining of bullion. This latter item on many mines outside of this group does not appear in cost sheets, this expense being deducted from the value of the bullion by the purchaser, the mine taking into account only the realized value.

SUMMARY.—The summary of the various items works out as follows:

	Per ton.	Percentage of total.
	s. d.	
Development	4 2.67	18.33
Ore extraction	8 3.38	35.95
Treatment	8 11.28	38.80
General expenses	1 0.86	4.65
Realization of bullion	0 6.27	2.27
Total	23 0.46	100.00

costs in this class of mining in Colorado, as conducted at a high altitude and during short seasons of from four to five months; under these conditions the matter of fixed charges becomes an important factor. The deposits are of glacial origin, most of them being lateral moraines, and as a result the material is not well rounded and does not wash through the sluices as easily as stream gravel. It is also of the heaviest specific gravity, making the duty of a miner's inch low, with a minimum grade of three inches to 12 ft. Most of our work so far has been by way of development. In our operations the duty of a miner's inch has been from 0.25 to 0.73 cu. yd. per 24 hours. This is about one-half the usual figure. In opening up this property it was necessary to drive a tunnel about 500 ft. long and raise through a shaft to open out a pit in order to get working room. The cost of this tunnel per linear foot was:

Labor, blacksmith, superintendent, etc.	\$ 9.825
Square sets	0.275
Lagging	0.880
Sluice lumber	0.533
Six-inch blocks for riffles	0.540
Powder	0.246

Total.....\$12.299

The size of the tunnel inside of timbers was 6 ft. at top, 7 ft. at bottom, and 7 ft. in the clear. The average per 24 hours (consisting of three 8-hour shifts—\$3 per shift per man, \$4 per shift for foremen) was 15.47 ft. working from four faces. The cost was high on account of very tight cemented gravel. Our sluices were double through this tunnel, 3 ft. wide in the clear, 3 ft. deep, bottoms of 1½-in. lumber, sides of 1¼-in. lumber. In laying a quantity of large slip-joint pipe on this property, the cost per foot was as follows:

Labor	\$0.0416
Cost of ties for pipe	0.0075
Cost of clearing right of way	0.0150
Hauling by team	00.050

Total cost per foot.....\$0.0691

The report for one month's work shows that it cost 38.7 cents per cubic yard to handle the material, including all expenses. This was due to the fact that we had not opened our pit in good shape for economic operations, and 10% of the boulders were too large for sluicing. The next month's operations show a cost of 26.6c. per cu. yd., or a reduction of 12.64c. per yard, as compared to the previous month. The following month was 23.5c., or a further reduction of 2.56c. per yard. In the fourth month the costs were 21.13c. per cu. yd. This shows a reduc-

tion again of 2.37c.; the boulders too large for sluicing were less than 4% of the material handled. Our best showing in the matter of costs was 11.25 cents. This low figure was only reached during a time when we had a maximum head of water and with conditions favorable as to character of gravel. In some places there are reefs of boulders of large size, and as we are working at right angles to the lateral moraines, when we strike one of

a five-ton crab for moving the crane, in place of the traction-gear, and it all works very successfully. The towers are about 300 ft. apart. Instead of using this cable-way with a standing cable, it was arranged with double block at the head-tower from the main drum, so that the whole cable-way and carrier lowers into a pit where the boat is loaded, hooked onto the carrier, the standing cable is drawn tight, the out-haul cable started, running the

carrier out where a plunger on the carrier strikes a bumper that is clamped on the main cable and automatically dumps the boat. Then the boat is returned to the pit. This arrangement (by actual test) has a capacity of over 300 loads, of $1\frac{1}{2}$ tons each, in 10 hours, making the capacity ample for all purposes.

Fig. 2 shows the double line of sluices just below where they leave the tunnel, it also shows a number of different sluices that we are compelled to use on account of shallow dump-ground. Alongside the sluices can be seen two under-currents that are in operation, each 6 ft. wide by 12 ft. long with $\frac{3}{4}$ -in. drop per foot. These under-currents are covered with cocoa matting and then 2-in. angle-iron riffles are used; these have proved effective in saving fine gold,

and from the test on the tailing we find that our losses are so small that commercially they do not count.

For this season's work we tested our gravel with the ordinary churn-drill, using a Loomis Machine Co. Clipper No. 2 with 6-in. casing. In this work we found that in our clean-up it yielded a saving of a little over 31% in our sluices above what our drill-test showed.

these reefs it reduces our capacity and increases our costs to over three times what it should be. In explanation of this working at right angles to the lateral moraines, I may state that they are deposited parallel with the hill, and in order to get grade for our sluices and dump-room for the tailing, it is necessary for us to cross these moraines, at right angles instead of following them.

On this property we found an American Hoist & Derrick Co.'s locomotive crane, 8 ft. gauge with 45 ft. boom, having a radius of 50 ft.; maximum lift, 50 ft., capacity, two tons. This had been used on a track in the pit, but it always gave trouble on account of the water splashing from giants and throwing sand on the friction brake; as a result the brake would not hold; there was also excessive cost for building track. This scheme for handling boulders was abandoned. The crane was changed by making a gravity cable-hoist of it for one season. We placed the boom vertical and with guy ropes to hold it. We used a 26-ft. post at one end of the cable, and by having a difference in elevation of some 15 ft. between the tail-post and the crane we were enabled, with 300 ft. of cable, to use this as a gravity cable-way, as shown in Fig. 1. A skeleton carrier was designed with 4-ft. wheel-base with trigger arrangement, so that by striking a block on the cable the stone-boats were discharged automatically. The next season, having moved up the gulch some distance, where the difference in elevation between a head and tail tower was very slight, we did not have room for a gravity hoist. In consequence, we built two 30-ft. towers, one at the crane and one for the tail. We took off the boom, swing-gearing and traction-gear of the crane, using one for out-haul cable and one for return cable, which enabled us to utilize this crane as a cable-hoist and keep it out of the pit altogether. We installed

Fig. 1. An Improvised Cable-way.

Fig. 2. Double Lines of Sluices.

This is something a little unusual in testing gravel by the churn-drill method. In this test we averaged about six holes per acre. The work was carefully done, as the drillman had instructions to not lead his casing with his bit.

The panner also had instructions to not amalgamate his gold and to not save the very fine flour gold. This accounts for the better saving in the sluices than the average return from drilling. Cost per foot of drill-hole, \$1.95. Cost per cubic yard of gravel developed by drill, two-tenths of a cent.

Asbestos.

*The name asbestos (from the Greek signifying 'in-quenchable'), as commercially used at present, covers at least two distinct minerals, having in common only a fibrous structure, and more or less fire-and-acid-proof qualities.

These are:

1. Amphibole or hornblende asbestos (actinolite).
2. Serpentine asbestos (chrysotile).

In external appearance and in chemical composition they are much alike, so much so, that, when the crystals occur in long slender prisms or in radiating masses, the mineral is called actinolite; but, when found in long slender flexible fibres, easily separable, it is named asbestos. The difference between the two minerals—between good and bad asbestos—will be at once perceived when the fibres, or long slender crystals, are subjected to tearing, twisting, or bending between the fingers. The good asbestos, applicable to the finer purposes of manufacture, will give up fine silky threads of great elasticity, amenable to the various spinning processes; while bad asbestos will split up into harsh, sometimes brittle, fibres, occasionally breaking up when rubbed between the fingers. The heat-resisting properties of both these varieties are approximately the same, so that, when this characteristic of asbestos is the only quality desired, the amphibole variety will give as good satisfaction as the chrysotile; but, whatever strength of fibre, as well as non-conductivity of heat is desired, the chrysotile variety is the only one that can be used satisfactorily. Chemically, the two species are much alike. Chrysotile asbestos is a hydrous silicate of magnesia, while the amphibole varieties are silicates of lime and magnesia, or compounds of silica with an earthy base, part of them hydrated. A special feature to be noted is that none of the varieties low in chemically combined water have much of the unctious feel which is so common a characteristic of the chrysotile varieties.

Chrysotile is the fibrous form of serpentine, and occurs in this rock in small veins, laces, or stringers. Its main essentials, to render it of economic value, are length, fineness and elasticity of fibre, tensile strength, flexibility, and power of fire-resistance. The Canadian chrysotile possesses all these qualities, the length of fibre being the principal factor which determines the grade. The main difference between asbestos and any other substance is its finely fibrous structure, and, at the same time, its property of fire-resistance. It may be said that, upon these two qualities, the great value of asbestos is generally based. Temperatures of 2,000 to 3,000° F. are easily withstood, while, with some varieties, a temperature of 5,000° F. has apparently produced no effect. Its property also of successfully resisting the action of acids is one of great value, and these combined qualities render asbestos of great importance in certain chemical operations, so much so that its use in laboratories and chemical factories is largely increasing. Chrysotile has great adaptability for spinning. For a long time the fibre, unlike any other, resisted attempts in this direction, the difficulty arising from the peculiar formation of the fibres, which, possessing perfectly smooth surfaces, slipped past one another when subjected to the spinning process. But all these difficulties have been overcome, and a single thread of fair tensile strength can now be made weighing not more than an ounce per 100 yards.

The hardness of Canadian chrysotile is from 3 to 3.5 Mohr's scale, and its specific gravity is 2.2 to 2.3. It has a lustre sub-resinous to greasy, pearly, wavy, and

silky. The color in mass is generally dark-green to blackish green. In most cases the fibre, when drawn out in threads, is white with a silky lustre. The fibre in nature is found arranged in parallel layers, and vertically to the bordering planes, is easily separable, and has a length from a fraction of an inch to several inches; the fibre of the great bulk of the mineral is, however, half an inch and less in length. As already indicated, chrysotile is a hydrous silicate of the following composition:

	Italian.	Canadian.
	%	%
Silica.....	40.30	40.87
Magnesia.....	43.37	41.50
Ferrous oxide.....	0.87	2.41
Alumina.....	2.27	3.67
Water.....	13.72	13.55

Chemical analysis indicates the cause of harshness of the fibre of some asbestos. The water in asbestos is combined, and may be driven off at a sufficiently high temperature. Where harsh asbestos is analyzed we find it to contain less water than the soft silky fibre. It is well known that, if soft fibre be heated to a temperature that will drive off a portion of the combined water, there results a substance so brittle that it may be crumbled between the thumb and the finger. There is evidently some connection between the consistency of fibre and the amount of water in its composition. It is probable that the harsh fibre was, as originally deposited, soft and flexible, and has been rendered harsh by having a portion of its combined water driven off by the heat, either produced by the movement of the associated rocks, or resulting from the injection of molten matter through volcanic action.

MEXICAN BELLS. — A bell of modern design is to be substituted for the old veteran which has called the faithful to prayer for the last three centuries in the church of San Juan at Aguas Calientes. *The Mexican Herald* says that since it has been decided to sell the old relic, which was set to swinging in the first church erected there after the conquest of the country by Cortez, a number of borings have been made into the bell to determine its worth. These show that it is very rich in both silver and gold, and its value has been conservatively placed at \$2,000. The weight of the bell is almost a ton, and as the assays show that it contains nearly 2% silver it holds \$800 worth of the white metal alone.

The date of the casting of the bell is shown to have been 1624, which shows how long it has been in service. At that time little or no attempt was made by workers in metals to extract gold and silver from copper ores. The precious metals were produced from the mines which carried lead as well, and as a consequence was much easier smelted. Copper ores were reduced in a crude way, and the gold and silver, if they were recognized, were allowed to remain. On account of the high values of silver and gold which the old bell has been found to carry, it is believed that large amounts of the precious metals were placed in the melting pot by church devotees, who at that time believed it a pious thing to do so. Silver was known to improve the tone of bells, and the gold may have been added as a kind of sacrifice, old records showing that in some cases the priests of that day induced the richer classes to give up their golden ornaments for that purpose.

The finding out of the worth of this bell is likely to have a far-reaching effect in the other churches here, as it is believed that all of the copper bells in this city are just as valuable as the one which has just been sold. The congregations of the other churches are ready to take the matter up.

ONE of the greatest of national assets is scientific discovery.

*Abstracted by L. S. AUSTIN from 'Asbestos, Its Occurrence, Exploitation, and Uses,' by FRIEDRICH, Mines Branch, Department of Interior, Canada.

Other Metallurgical Methods at Pachuca.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

Pachuca affords examples of other methods besides the ancient *patio*. Some of these I shall describe :
The Hacienda La Union offers much that is interesting to the metallurgist. The process is that of Kroencke, used in Chile, but modified by the manager, Francisco Narvaez, formerly a captain of artillery and graduate of the military engineering school of Chapultepec. As a military officer he visited the United States three years ago, and, becoming much interested in metallurgical practice, he resigned from the service to undertake the work for which he has since shown so much aptitude.
The scheme of milling involves first a Sturtevant roll-crusher, which reduces the ore from 3 or 4 in. to 1-in. diam. An Imperial shaking-screen sizes the material to 16-mesh ; the undersize is fed into an Abbé tube-mill of 5-ft. diam. and 22 ft. long, while the oversize passes

ton. One of these mills, for example, worked from February to June without stopping once for repairs ; and with the ordinary unskilled labor, it ground 15 to 18 tons per 24 hours from 1½-in. size to the fineness recorded in the tests just quoted. The cost per ton did not exceed one *peso*, or less than 50 cents per ton.
At the time of my visit there was one Krupp tube-mill, with other foundations ready for the Abbé tube. The Krupp tube crushed 50 tons to 100-mesh in 24 hours. It was preceded by a Krupp ball-mill, which reduced the ore from 1½-in. size to 24-mesh. It is necessary to grind dry, on account of the barrel process, which constitutes the main feature of the treatment. With the use of Chilean mills, as at the time of my visit, it was necessary to dry the product. Both ball-mill and tube work dry. Sillex linings in the tube last three years. The use of the Chilean mills yields iron which becomes oxidized by the water, while the iron, worn away from the balls in dry crushing through the Krupp mill, is in a metallic condition and in an amount suited to the later chemical reactions in the

An Old-Fashioned Chilean Mill.

through rolls, without springs, with 14 by 27 in. faces (made by the Denver Engineering Works). The amount of iron that gets into the pulp is only 2% ; this fact is important in view of the chemical treatment that follows. Capt. Narvaez was led to adopt this method by reading Richards' 'Ore Dressing.'
Later on, without stopping the regular operation of the mill, he intends to replace the barrel amalgamation process by cyanidation; as far as grinding is concerned, his results indicate that Chilean mills will more than hold their own against the competition of newer devices for pulverization. They permit of a very fine grinding at a low cost per ton. From an average of thirty sizing tests, made on the product of the Chilean mill at this *hacienda*, Capt. Narvaez obtained the following results :

	Percentage.	Assay in silver gram	Percentage of assay-value retained.
Finer than 200 mesh	80	1	33.65
Between 200 and 150 mesh	4.75		0.27
" 150 " 100 "	13.45	385	0.47
" 100 " 80 "	1.50	355	0.48
" 80 " 60 "	0.41	345	0.01

The original assay of the ore gave 1,102 grams per metric

barrel. The ball-mill is charged with four balls of 8 kilo. each per day, this representing the iron abraded from the balls themselves and the lining also. For setting the sillex lining in the tube, a common cement with two parts of sand is used ; it sets in three days. Trouble has been made by the fact that some of the sectional pieces of lining are not cut to the right curve ; but only three dropped out after being in use for a month. The flint pebbles are bought from Indians, who will not divulge the locality whence they bring them. They are paid 35 *pesos* per ton, while the imported pebbles cost 75 to 90 *pesos* per ton. The tube has no screen, the material passes through the length of it and is then discharged.
In the new plant as it will be re-arranged, the Krupp ball-mill will deliver its product to the Abbé tube, for re-grinding, and both will work wet, instead of dry. The ore that goes to the Chilean mills will be crushed to 1½-in. size in a breaker and from the Chilean machines the pulp will be pumped direct to the vats and cyanided. From the day in January that E. M. Hamilton, associated with Charles Butters, made a cyanide test on the ore at this *hacienda*, Capt. Narvaez has made more than 200 tests,

obtaining an extraction of 98.12% on the silver and 88.4% on the gold. He believes that extraction of the gold is less than that of the silver because the gold is encased in the pyrite and, to liberate it, re-grinding is imperative. But the ore contains only 5 grams gold per ton, therefore it remains yet to be proved, by further experiment, whether it will be necessary to re-grind more than 20% of the ore.

It was the custom formerly to use the *camonero* to move the product of the Chilean mills into the *patio* where it was allowed to dry in the sun, but the change to dry crushing will obviate the necessity for this practice. At the time of my visit the Chilean mills were being operated without screens, the discharge being by overflow, thus saving labor while using a great deal of water, of which there was plenty. The tires on the Chilean mills are changed so as to equalize the wear; they last two years; the dies last only about eighteen months. Each mill requires 10 h.p. The Fraser & Chalmers, or Union, type of Chilean mill, modeled after Walker's patent, gives good service, grinding 15 tons per day; those of other makers treat only 8 or 9 tons, because the runners do not maintain a vertical attitude. Seven Chilean mills ground 60 to 70 tons per day, while the Krupp ball-mill crushed 50 tons per day of 24 hours.

The product from the grinding machinery goes to the barrel room. There are 13 barrels originally made by Allis-Chalmers and since modified on the spot. Each barrel is beneath a hopper that holds a charge of 4.7 tons. As this is filled by the cars (each carrying half a ton) a grab sample is taken to determine the percentage of moisture and the richness in silver; from the aggregate of all these samples a mean of the iron assay is obtained for the week, so as to indicate if the amount be sufficient to effect precipitation; if not, zinc is added to help precipitation and because it has been observed that the gold recovery is better when zinc is employed in addition to the iron. The cuprous chloride is proportioned to the amount of silver amalgam in the barrel, decreasing from, say, 60% Cu_2Cl_2 at the beginning of the month to 22 or 24% at the end. The silver in the charge is precipitated on iron. The barrel treatment consumes eight hours; it requires four hours to charge and re-charge. Mercury is added half an hour after the treatment has begun. Salt is added in the ratio of 27 kilo. of salt per ton of ore; no more copper sulphate is added than that required when making the copper chloride solution. The loss of mercury per month is 800 grams per kilo. of silver; the loss of silver is 6.88 to 9% when treating three charges per day.

The barrels are washed out once per month, during the remainder of the time the silver amalgam accumulates inside of them; it is taken out every other day, in such an amount as to yield 250 to 300 kilo. of silver bars.

From the barrels the pulp goes to six washers or agitators, and from them to *apuros* (or wells) underneath, where the silver amalgam is secured. Thence the tailing passes outdoors to a crude form of conical buddle. The 2,300 to 2,500 tons of tailing per month contain 110 to 120 g. silver per ton and yield 25 to 30 tons of concentrate assaying 2 to 3 kilo. silver and 30 to 40 g. gold per ton.

When Cu_2Cl_2 is added, there is a formation of AgCl and sometimes of HgCl ; then if zinc (in the form of strips of metal, not shaving) is added, the metallic silver is precipitated and also the mercury. Sodium hyposulphite was tried, but, although useful, it was not found necessary. The purpose of it was to regenerate the Hg from the HgCl formed, and the same end could be gained by the motion of the pulp in the barrel—a motion resembling the manual operation termed *refregar* or rub-

bing by the *peones*. If there is enough iron in the pulp, it will precipitate the silver, but the amount of iron is not under control, hence the addition of zinc if the iron be inadequate. From the wear of the lining and of the balls in the Krupp mill, Capt. Narvaez was getting 600 g. iron per ton of ore, this being the amount which practice has demonstrated to be necessary. Whenever, for any reason, the amount is less than that specified, zinc is added. Experience has proved that, although 1,200 g. iron is adequate to precipitate the silver in a charge of two tons of ore and give bullion 999 fine, yet zinc is always needed in order to increase the gold recovery. If this be done, the bullion will assay 960 g. silver and 2.8 g. gold per kilo., while, if the zinc be omitted, the gold will not exceed one gram per kilogram.

The total extraction of silver by this barrel process is 95%; that of the gold from 35 to 75%. In the concentrate, 5% more of the gold is saved. The gold is to the silver in the ore in the ratio of 5 to 1,000. The ore treated at the mill is worth as delivered 23 to 25 pesos per ton, the cost of extraction (*maguila*) last year was 10.50 per ton, and the profit 8 pesos per ton. The ore assays generally 1.2 kilo. silver, equal to about 41 pesos per ton.

The bulk of the ore obtained from the mines of the Real del Monte Co. is similar to that treated at the Hacienda La Union, although in the Corteza mine of that company there is produced the class of manganese ore called *quemazones* on account of its black appearance. Such ore is not suitable for the process of amalgamation because of the loss of mercury, following upon the familiar reaction in which a mixture of salt, manganese dioxide, and sulphuric acid evolves the chlorine destructive to mercury. At the time of my visit, this ore from the Corteza mine went to the Hacienda de Loreto; it was a black silicious material containing 8% manganese dioxide. The treatment to be described has ceased lately, the mill having been utilized to test the adaptability of the cyanide process to this class of ore. At first the idea was to erect a ball-mill, followed by a re-grinding tube, as at La Union, but later it was decided to install two sets of rolls, of the same dimensions and running at the same speed, the first pair for reducing the ore from 3 to $\frac{3}{4}$ in. and the other for grinding to 16-mesh; between the rolls there is a trommel, and thence the material goes to the tube-mill. Trouble was caused by the moisture in the ore, a coating being formed on the silex, requiring removal with a chisel.

I shall now describe the process for which the original plant was built; it was a modification of the Francke process, originally developed in Chile. On arrival, the ore passes through a Blake crusher and then it is fed to the rolls, which delivers it to a trommel provided with a 70-mesh screen; the undersize goes to the bins, while the oversize passes to a tube-mill (*cilindro remolador*), also made by Krupp, where it is re-ground with flints (*pedras de chispa*) at the rate of about 40 tons per day. Then it joins the previous undersize in the bins. Next come four calcining furnaces, each with a capacity of 20 to 30 tons per day. The charge of 10 tons is given 1½ hours. Salt is added in the proportion of 18 kilo. per ton of ore. The calcined product drops below the furnace and is taken in wheelbarrows to the cooling floor. Here it is shoveled into vats (*tinas de Bolivia*) where it becomes mixed, through the agency of revolving arms, with cupric chloride (CuCl_2) and mercury. Copper plates placed along the sides of the vats catch any gold in the pulp. Each vat is 3 metres deep and 2½ m. diam. During the treatment steam enters through the bottom. Three charges of nine tons each are treated per day. Then, after four hours of mixing, the pulp is discharged from these vats, through three openings at successive

levels leading into pipes which empty in a mercury trap (*apuro*) outside. Here the silver amalgam is caught. The tailing passes on to two settlers, without further addition of mercury, the purpose being to arrest any amalgam escaping from the preceding operation. Below each settler there is an *apuro*, which finishes the treatment.

Only one shift of 12 hours (by day) is employed. Two men work at each furnace; these also do the wheelbarrow work. The pans occupy three men; in addition, there are two roustabouts and one foreman. Each charge is

The tailing from the vanners goes to big ponds, where it settles to a thickness of 8 to 9 in. of pulp. The *camonero*, or horse with the drag, is employed to move the slime to the different rectangles in which the mixing stage of the *patio* is carried out. There are seventeen rectangles (50 metres wide and 80 m. long), for the treatment of as many charges or *tortas*, each being equal to 220 to 300 tons. The mixing is done, not in the old way by horses, but with a mechanical harrow, such as has been described in connection with the Hacienda Guadalupe. In this case also, it seemed to me that the mechanical mixer failed

in its service, the material was too wet, the harrow omitted to turn the pulp over and simply passed through it, without overturning it so as to cause aeration. Moreover, as the harrow cannot be made to scrape the floor, there always remains at the very bottom an inch or more of pulp that is not moved and which, therefore, escapes metallurgical treatment. The clean-up was done as at the Hacienda Guadalupe, so that the description need not be repeated.

The retorting is worth noting. The bricks of amalgam are built up in a pyramid of about one ton weight standing in an iron pan, the bottom of which is perforated. A hood is then dropped over it; a flue from the furnace enters through an aperture near the base of the hood. The mercury, as it is distilled, passes out at the bot-

tom into a stream of cold water by which it is condensed. The ratio of mercury to silver in the amalgam is as 8 to 1.

At the Progreso mill, which was built by that representative American millman, M. P. Boss, there are 50

An Abbé Tube-mill, Just Arrived.

not followed by a clean-up; the amalgam is allowed to accumulate.

The mill was idle at the time of my visit; it is probable that there was a heavy loss of mineral which was ground fine in the tube and then pulled by the strong draft into the chimney of the calcining furnace. Also there is likely to have been loss of silver by volatilization as chloride.

The machinery is operated by electricity and in contrast to this flagrant modernism is the shrine in the roaster house, with its picture of the Virgin. In other parts of the establishment there are crosses, decorated by withered flowers. Everywhere in the *hacienda* there is an exuberance of masonry; the works are enclosed by massive walls, like the ramparts of a fortress of the old-fashioned kind.

Such ore as does not contain manganese oxide, and comes from the other mines operated by the Real del Monte Company, undergoes direct concentration followed by amalgamation. This quartz ore is reduced by two Blake crushers and then passes to 14 Chilean mills, which discharge through 80-mesh screens. The feeding is done by automatic (the Hendy Challenge) machines. From the Chilean mills the pulp goes to 32 Johnston vanners, which extract the pyrite, not only to get at the gold that is intimately associated with this pyrite, and to take out half the silver in the ore, but also with a view to simplifying the *patio* process that follows and which would otherwise need the addition of more chemicals. The 14 Chilean mills grind 800 to 900 tons per week; the crude ore contains 1 kilo. silver to 5 or 6 g. gold; the pyritic concentrate represents 4 to 4½% of the crude ore; the richer concentrate, with 9 to 10 kilo. silver and its proportionate amount of gold, is shipped to Germany, while the poorer, with 4 to 6 kilo. silver, is sent to the smelters at Monterey and Aguascalientes.

A Krupp Tube-Mill.

stamps, followed by four Kinkead mills; the latter is a machine for re-grinding. Then come two chemical mixers, 16 pans and four settlers, followed by four New Standard and six Johnston concentrators. Just outside

the mill I saw the old-time Mexican method of concentration by the *planilla*, or little plane. The material is heaped up at the head of an inclined plane, 8 to 10 ft. long, 4 to 4½ ft. wide; the operator throws the water with a horn, by successive regular sweeps of his arm; at intervals he scoops up the material with a wooden shovel, and as the heading becomes cleaned (or concentrated), he moves fresh material to the top of the incline. Mexicans can be seen operating the *planilla* in the streams that receive the tailing from the mills at Pachaca and Guanaquato. The process resembles 'trunking,' or the treatment of slime from the tin-dressing floors in Cornwall.

A Department of Mines.

At the Trans-Mississippi Congress, in session at Kansas City on November 22, Mr. Victor C. Alderson, president of the Colorado School of Mines, spoke on the need of a Department of Mines and Mining, with a cabinet officer at the head of it. Mr. Alderson said in part:

The mining industry is basal. A department would crystalize and bring into harmony all the various influences to upbld and dignify the industry. Today the miner gets the title to his claim from the land office, more or less untrustworthy. His maps are too late for his use; his information is too old. Prompt advice, assistance, co-operation, is not for him. A department could remedy this state of affairs. In the second place it would revise our mining laws and eliminate much of the legal stupidity in laws made by men who know nothing of the industry. There should be a recognition of mining commensurate with its importance. In the third place it could conduct researches such as are carried on for the benefit of the agricultural industry. Today there is no place where we may turn for information or advice. Such research would open new avenues of prosperity, reveal fresh opportunities for the investment of capital, and provide work for tens of thousands more men. Such a department would secure the enactment of new laws. It is not a work for mere politicians, nor for any particular State, but from the standpoint of national development. The duty of the Government is to foster research and to give dignity and standing to the industry.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The rocks from Ures, Mexico, marked W. L., are highly silicious metamorphic rocks, apparently baked shales and quartzite.

The quartz and silicious limestone from Ogden, Utah, marked L. F. H., can be used for glass-making, although the limestone may be too refractory.

The specimens from Table Rock, Cal., marked J. J. G., are: No. 1, Rhyolite tuff; No. 2, Hornblende Porphyrite; No. 3, Hornblende Porphyrite or Andesite; No. 4, Rhyolite; No. 5, Porphyrite.

The specimens from Eagle, Alaska, marked C. A. B., are: No. 1 to 5, Quartzite and quartz rocks containing granular pyrite. Some of the pyrite has oxidized to dark brown limonite. No. 6 is Dolomite.

The specimens from Belgrade, Montana, marked H. M., are: No. 1, altered Quartz-mica rock filled with pyrite. No. 2, Quartz with pyrite oxidized to limonite. No. 3, Calcite and yellow clay. No. 4, banded Quartz and chlorite.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

The statutes of Missouri require the owner, agents, or operators of any mine to keep on hand a sufficient supply of timber to be used as props, and that when a miner requests the use of props in the mine they shall be sent to him without unnecessary delay. This statute is not limited in its application to miners at work for wages, but extends as well to those mining coal at a fixed price per bushel.

McKinnon v. Western Coal & Min. Co., (Mo.) 96 S. W. 485.

A statute, providing that the owners or operators of a mine should keep on hand props for use in the mine when requested, was held to mean that the props must be promptly furnished when requested by a miner; but that it did not impose upon the owner or operator of the mine the duty of knowing when such props were needed and supply them without being requested. The word "required" was construed to mean "requested," and that the meaning of the statute is that when a miner makes the request the mine owner or operator shall be in a position to furnish the props or send them into the mine without delay.

McKinnon v. Western Coal & Min. Co., (Mo.) 96 S. W. 485.

The statutes of Tennessee regulating the operation of mines and requiring the employment of what is termed a "certificated mine foreman," and conferring on such foreman control of the mine with reference to the duties specified in such statutes and secured the faithful discharge of such duties by the imposition of penalties. In an action by a miner against the owner of a mine for injuries caused by the negligence of such foreman as provided for by the statute, the Court held that the mine owner was not liable for the negligence of such statutory foreman in the performance of the duties imposed upon him by the statute.

Sale Creek Coal &c. Co. v. Priddy, 96 S. W. 610.

The lessor of premises to another for the purpose of exploring for oil and gas by drilling a well cannot recover damages for the lessee's failure to drill the well, without showing that oil and gas existed in the territory to be developed.

Duff v. Bailey, (Ky.) 96 S. W. 577.

The United States statutes, providing for the issuance of patents for mineral lands and the prosecution of adverse claims to mining locations, apply only to adverse claims arising out of independent, conflicting locations of the same ground, and not to controversies between co-owners claiming under the same location. And an owner of an interest in a mining claim, who has been excluded by his co-owner from an application for a patent, may adverse or protest such application and maintain an action in support thereof, under the statutes which permits an action for possession of an interest in realty to be brought by a tenant in common against his co-tenant, where the law has actually ousted the former, or where he has done some act or acts amounting to denial of the former's right as a co-tenant.

Davidson v. Fraser, (Colo.) 86 Pac. 694.

The record of a notice of location of a lode claim, as required by United States statute, is only effective to prove the bare fact of the record of such notice; this record is not evidence that the notice was posted on the claim, or that the location was so marked on the ground that its boundaries could be readily traced, that they included the apex of a lode, the existence of any valuable mineral in place, or that the necessary assessment work had been done; proof of all these facts are essential to the validity of the location, in addition to the introduction in evidence of the record of the notice. A notice of location of a lode claim which fails to contain a description of the claim by reference to a natural object or permanent monument by which it could be identified, as required by the United States statute, is ineffective for any purpose.

Mutchmor v. McCarthy, 87 Pac. 85.

The Old Way and the New.

Written for the MINING AND SCIENTIFIC PRESS
By FRANK DRAKE.

In the year 1864 some prospectors invaded the deserts of the Great Basin and staked out a few mining claims on the western slope of the White mountains in Inyo county, California. The Government had not yet enacted any laws governing the occupation of mineral land. The first claims were limited to the small areas prescribed by the custom and laws of the miners of the Pacific Coast at the time. When the Congressional act granting miners' rights and defining the size of claims went into effect, they or their successors re-located their claims, and a large area was covered by their holdings. The workings were tentative, only sufficient to hold the titles. Practically all real development was on the claim now known as the Southern Belle.

A description of the early operation and of the present condition of the mines will present many interesting features.

Several veins, chiefly quartz carrying free gold, traverse a formation consisting of schist and shale, locally termed slates. To open what at the time was supposed to be the main vein of the locality the early workers determined on a small cross-cut 'tunnel.' Starting on the mountain side, well below the outcrop, they drove their adit easterly and in a direct course for 120 ft. Had they continued on this course they would have intersected the vein within 50 ft., but for some reason, now hard to conjecture, they then turned south—at right angles—and ran 110 ft., nearly paralleling the vein only 50 ft. away. At this point they made a right angle to the left, pursuing an easterly course again for 70 ft., and cut their ore, which was three feet thick. Here they again turned at right angle southward and followed the vein for 50 ft. At this point they sank 560 ft., following the ore at a dip of about 40°. The raising of material from this shaft was first done with the ordinary one-man windlass. Then by relays of windlasses, one stationed above the other; then by a skip on a skidway. The skids were placed securely on the floor of the incline-shaft, making a run-way for the skip. The skip was constructed of a plank some five feet long, with strips of scantling on the under side to serve as guides inside the skids. Sacks of ore were piled on the skip and the vehicle transported upward to the tunnel-level by means of the windlasses. Finally the skids were replaced by a track and the skip by a car. The track consisted of 2 by 4 in. scantling topped with strap-iron, and was extended through the drift and tunnels to the dump outside.

The orebody actually mined and milled was taken out of a block of ground 100 ft. along the vein and three feet wide, from the bottom of the shaft to the tunnel-level 560 ft. overhead. Operations were then suspended. Many years were consumed in making these workings. I am told that the little stope described supplied the owners with more than \$150,000, besides abundance of specimens, chains, charms, rings, and jewelry to a multitude of relatives, visitors, friends, and employees.

I went into this old tunnel. No remnants of pipes appeared, nor any evidence of supports for pipes. There was no air-shaft, no opening to daylight save that small, crooked adit and the drifts with their numerous angles—nothing to get movement to the confined atmosphere, 560 ft. down the shaft. A thousand feet of narrow crookedness! Leave an unlighted candle in those old workings and it melts in fifteen minutes. Amazed, I asked how men could live in such a place. One man who had worked there answered, with a grin, that "They had no air," and that they used powder, too! The best of men

in such a place could give but feeble physical effort in stoping or moving ore. The work must have gone slowly and been costly. The owners dropped out, sold out, and the property passed into other hands.

During the period of mining, the motive power used, though primitive, was not unprecedented. Its application, however, was unique. A one-horse whim was built on the ground and installed at the mouth of the adit. From this whim a small cable was carried through the tunnel, around the several corners, to the shaft and down it. The car was attached to one end of this cable. Guide rollers at intervals and sheaves at the angles furnished support. When the car had been filled in the shaft the horse attached to the sweep of the whim outside was notified and he proceeded patiently and faithfully to walk around, winding the cable on the drum above him. The mucker followed the car on its slow journey and dumped the contents onto a heap near the whim. Then he pushed the car through the tunnel and drift to get another load. As he shoved the car along, he replaced the dragging cable in guides and sheaves. By this method the little car, propelled by the horse, daily brought about 5,000 lb. of ore up the 560 ft. of incline shaft to the level, then around the corner, along the drift to the cross-cut, then around the corner, more tunnel, another corner, more tunnel and so on to the dump. Another handling by shovels (they had no bin) put the ore into sacks; then onto pack-trains or wagons for transportation, to an arastra at first, to a steam-driven mill later, a couple of miles away. The gold was free and amalgamation easy. This was the only 'easy' part of the entire process in those days.

Adverse criticism after an event is often unjust. Environment, extremely adverse conditions, disagreements among owners, usually over petty trifles, influenced and often controlled the doings of men. The facts stated here are for the purpose of comparison, illustration, and not in a spirit of criticism.

The ownership of several of those early claims recently passed to new men, old miners. The property now consists of seven claims, 140 acres. The new owners—there are only two of them—did not resume work where their predecessors left off. They started a shaft on a claim, the New Year, 2,000 ft. south from the old workings and on a fair outcrop, partly developed on the surface years ago, and followed the vein down 100 ft. Here, on cross-cutting, they found an orebody 25 ft. between walls, all free-milling ore; dip 60°. At a depth of 175 ft. the vein is 27 ft. wide. Still farther, southeast, on a contiguous claim, the Bullion, another shaft, at 130 ft. opened a vein full 20 ft. wide, all free-milling ore. At a depth of 300 ft., the vein is still gaining in strength.

On the New Year, hoisting is done with a 10-h.p. electric motor. On the Bullion claim, another electric motor has recently been installed. The Bullion is above the New Year and cars take the Bullion ore over a T-rail tram to a point above the New Year hoist and dump their content through a long chute into the bin of the New Year. From this bin trains of steel cars take the ore of both mines over another T-rail tram to the mill.

Of the mill it suffices to say that it is modern. Grizzley and rock-breaker deliver to a big ore-bin, whence automatic feeders supply the 10-stamp battery. Then comes plain amalgamation, on copper plates. A ditch three miles long brings water from a neighboring cañon and delivers 40 in. under 280-ft. pressure to a Pelton wheel. There is power enough for ten additional stamps. The mill treats 35 tons of ore daily. The water from the mill-wheel is led immediately to a second penstock where it enters a pipe extending down the hill to another Pelton wheel, where it drives an electric generator of 60-h.p. This runs the motors at the hoists, lights the whole camp,

and operates an air compressor. This power—the water-wheel and generator—is under the control of a governor by which practically normal and uniform pressure is maintained without burning armatures or blowing fuses. The turning on or off of a 16-c.p. incandescent light is noted by, and actuates, the governor at the power-house. By this wonderful machine an increased demand for power at one of the hoists is instantly met upon the movement of the hoisting lever at the shaft.

The extraction in the mill on plates alone is surely a record. A. E. Vandercook, the manager, assured me that the tailing from a \$5 to \$7 ore shows only 40 to 70c. per ton. There is practically no iron, no sulphides. The gold as it comes from its matrix is pure and clean. The ore is of good paying quality and I submit that this saving of gold on plates alone is a record.

The mine is at the base of the range, five miles by good road from Laws, the nearest station on the C. & C. railroad. From the camp and all the works the upper end of Owens valley appears, spread out like a patterned carpet on a floor.

TIN MINING IN BOLIVIA.—The trying condition under which the rich tin deposits of Bolivia are worked detracts from the success of their development, although the high percentage of tin would make them the richest tin mines in the world under ordinary climatic conditions. The Quinzi Cruz tin mining region is situated at an elevation of from 15,000 to 17,500 ft. above sea-level. Tin occurs in altered slate, with occasional bands or seams of porphyry, conforming to the strata. The tin ore is a mixture of cassiterite and pyrite occurring in a slaty silicious gangue in bedded deposits. A most peculiar feature is noticeable in connection with the value of the ore. That is, that the highest mines—those, say, above 16,000 ft.—are richest, the tin contents in lodes one to one and a half metres in thickness, running up to the average of 10% metal, whereas lodes in lower country are worthless. One mine, the Monte Blanco, was recently sold to a Chilean syndicate for £170,000 cash, a high price for an undeveloped mine. It is probably a good field, and will be developed in time, but climatic conditions are terrible at that altitude. Only Indians born in the locality can work, all imported men being unable to do more than just move about, on account of the rarified air. Although the district is well in the tropics, snowstorms are of frequent occurrence, both in summer and winter. The nativeso-called miners are now receiving five to six bolivianos per day (about \$2) and the men are very scarce at that. The mine-owners, therefore, are endeavoring to secure Government sanction to import Japanese miners, as being hardy. Up to the present only primitive means are employed to treat the tin ore. The ore is pounded by means of a stone rocker—termed *kimbelletty*. The rough material is picked out and re-crushed. The stuff is afterward run over jiggers, steamed, and the slimes buddled. The tin is of a comparatively poor quality, and is only dressed up to 55 per cent.

GOLD STEALING.—The Royal Commission in session at Kalgoorlie, Western Australia, is unearthing several scandals and provoking some humor, both of which are useful. It has become usual for witnesses to admit that they destroyed "the butts of their check-books" and that they kept no accounts at all. In one case, a hole in the ground was used as a blind to explain the possession of stolen ore, and the witness gave the name of his mine as Randall's Hard to Find. When compelled to show the mine, the official who made the inspection found some shallow abandoned workings decorated with garbage and empty tin cans. The 'mine' had not been worked for many years.

Concentration in Montana.

By C. W. GOODALE.

*As the specific gravity of the ingredients of Butte ores is so widely different—the copper mineral varying from 4.5 to 5.5 and quartz being about 2.6—the question of separation is a comparatively easy one. The maximum size of the particles used in concentrating at present is 1/10 in. An average analysis of Butte ores may be set down as:

Si O ₂	54.5 %
Al ₂ O ₃	10.1 "
Fe	10.9 "
S	13.9 "
Cu	4.14 "
Ag	1.68 oz. per ton
Au	0.0127 " "

Twenty-eight per cent of the Butte output is available directly in the blast-furnace. Its analysis is approximately:

Si O ₂	26.3 %
Al ₂ O ₃	4.6 "
Fe	24.3 "
S	30.9 "
Cu	10.77 "

The fine concentrate requiring roasting and reverberatory smelting will average:

Si O ₂	17.5 %
Al ₂ O ₃	3.7 "
Fe	29.5 "
S	36.1 "
Cu	8.68 "

The slime from the tanks and overflow of concentrate constitute only a small percentage of the output. Forty per cent of the weight of the crude ore is taken from the plant as concentrate. After calcination there remains 80% of the weight of the concentrate. McDougal roasters reduce 35 to 36% S to 9%, but at the same time iron is oxidized, so that the weight after roasting remains practically the same, or 32% of the crude ore. In reverberatory smelting the matte produced is equal to one-fourth of the charge. The converter delivers 50% of the matte as blister copper, a 99% product. The final product is then 4%, or 80 lb. copper per ton of ore.

Electrolytic refining gives cathodes of 100% copper with gold and silver slime settling in the box. The cathode must be re-melted into three grades of product, namely: Wire-bars, cakes, and ingots. The copper absorbs sulphur from the coal, which is blown out by air, and a final reduction effected by poling.

Five-tenths horse-power per ton of ore is required for concentration. The costs in concentration may be given as:

Labor	80.30
Power	0.10
Supplies	0.08
Insurance, management, etc.....	0.02
Total cost per ton	80.50

7,680 gal. water are required per ton of ore in concentration.

In electrolytic refining, 2,500 h.p. will produce 4,500,000 lb. copper per month.

Hydraulic classification means a great deal of water. This may be reduced and the slime thickened by using conical vats. The slime is admitted at the centre of the vat and a concentration of six to one effected. Instead of settling, slime may be concentrated on wooden-deck tables. The volume of slime may be reduced by a change in apparatus used, for example, a Hancock jig required 919 gal. water per ton, while the Evans required 3,457 gallons.

It is claimed that fig trees can be grown on the piles of gravel deposited from the dredges at Oroville. An effort is to be made to level the ground for cultivation.

*From *The Bulletin* of the Colorado School of Mines.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

ROPE-SOCKET.—No. 833,548; James K. Putnam, Montpelier, Indiana.

The combination of a body having a socket formed therein with corrugations in its outer portion, a holder slidably mounted in said socket, a socket-engaging jaw carried by said holder to force said jaw into engagement with the corrugations of said socket, and means for retaining a rope or the like in said holder.

DUMP-CAR.—No. 834,934; Henry A. Reader, Cleveland, Ohio.

In dumping-cars, a supporting-frame having straight transverse tracks at each end, in combination with a triangular car-body having one of its angles set centrally of said frame between said tracks and the other angles at the sides and top thereof, a segmental carrier on each end of the car-body above the lower angle thereof adapted to roll on said tracks, and a projection from the middle of each segment provided with a roller on the end thereof, and a fixed upright centrally behind said tracks having diverting slotted wings adapted to be engaged by said roller as the car is rotated, and means at the ends of said segments to hold the car-body in upright position.

ORE-CONCENTRATOR.—No. 833,415; Frank E. Pearson, San Francisco, California.

An improved ore-concentrator consisting of a main frame having vertical end standards, transverse beams connecting the upper portions of said standards, an independent frame within said main frame below the top of the standards, an endless belt operable in the independent frame, boxes

mounted upon the transverse beams of the main frame, parallel shafts extending from one transverse beam to the other and having their ends supported in said boxes, said shafts serving as top braces for the standards of the main frame, and said boxes being adjustable in the direction of the length of the transverse beams, rods mounted on the shafts said rods depending from the shafts and having their lower ends pivotally connected to the independent belt-carrying frame whereby said latter frame is hung directly from the shafts, the opposite ends of said shafts being independently adjustable, and means for oscillating the independent frame in a transverse direction.

ORE CONCENTRATION.—No. 835,479; Henry L. Sulman, Hugh F. Kirkpatrick-Picard, and John Ballot, London, England.

The process of separating powdered minerals from one another which consists in suspending the powdered minerals in a liquid, subjecting the mixture to a gas-pressure and thereafter relieving the pressure whereby bubbles of gas are liberated in the pulp and carry certain minerals to the surface.

PROCESS OF OBTAINING METALS AND COMPOUNDS THEREOF.—No. 833,472; Hermann Mehner, Berlin, Germany.

The described process which consists in bringing in contact with each other a compound or compounds of a metal or metals, an agent capable of generating metallic vapors from said compound or compounds, and an incandescent fluid heat-carrier, and leading off the vapors and gases for separation, substantially as described.

PROCESS OF TREATING COMPLEX SULPHIDE ORES.—No. 832,341; William G. Rumbold and George Patchin, London, England.

The process for the extraction of zinc and other metals from complex oxidized ores containing zinc; consisting in passing over successive lots of crushed ore a solution consisting of ferric sulphate, sulphuric acid, sodium chloride and water, until such solution becomes saturated with dissolved matter, such dissolved matter consisting of the zinc, and also the copper, cadmium, manganese, nickel, cobalt, antimony, lead, bismuth, and tin, or any or all of these metals when contained in said ores, a small proportion of ferric sulphate being employed in the solution in relation to a large amount of sulphuric acid whereby the ferric sulphate is continuously decomposed and regenerated until all the free acid has become neutralized substantially as set forth.

An Important Pumping Plant.

The installation of the pumping and power plant for the Denver Union Water Co., at the mouth of Platte cañon, twenty miles from Denver, is unique and interesting. It is unique on account of the manner in which the machinery is installed, and interesting on account of the method employed in furnishing the water supply for a city the size of Denver. The system was designed by George T. Prince, chief engineer for the water company, the machinery being supplied and installed by The Denver Engineering Works Co. In order to get the best results from the plant it became necessary to mount the 80-h.p. Victor water-turbine on a steel frame-work 14 ft. above the engine-room floor. This turbine is driven by water brought from the Platte river, a considerable distance, to a large reservoir about one-half mile to the east of the power and filtration plant and through a 36-in. pipe to the turbine. The turbine is used for operating the De Laval pumps, and the water discharged from the water turbine is delivered to the filtration beds. There are six beds or tanks in all containing something like nine acres. Each bed or tank is covered on the sides and bottom with six inches of concrete, about seven inches of coarse gravel, five inches of medium gravel, and

Commercial Paragraphs.

THE JEFFREY MANUFACTURING Co. of Columbus, Ohio, issues Catalogue No. 31. It is a handsome publication devoted to pulverizers and their appurtenances.

THE INGERSOLL-RAND Co. of New York has issued Bulletin No. 2,011 on the Little Jap hammer drill. It illustrates the varied uses to which this useful tool is put.

THE WELLMAN-SEEVER-MORGAN Co. of Cleveland, Ohio, issues an attractive booklet entitled 'What We Do' in ore and coal handling machinery. The illustrations tell their own story.

THE INGERSOLL-RAND Co. has issued Bulletin No. 2,008, on Imperial Motor Hoists and Stationary Motors. The pamphlet contains complete descriptions and tables, as well as lists of machine parts, for the convenience of purchasers.

THE CHICAGO PNEUMATIC TOOL Co. issues a handsome catalogue devoted to a description of the Franklin air-compressors. Constructive principles are given in detail and numerous tables and formulas render the publication useful.

THE magnificent plant of the Santa Ana Valley Irrigation Co. was built by the WESTERN GAS ENGINE Co., of Los Angeles. The machinery works admirably and will

Denver Union Water Co.'s Filtration Beds and Power-house.

three feet of sand, through which the water is allowed to filter, after which time it passes to the mains for use in the city. In case of accident to the water turbine a 75-h.p. De Laval steam turbine may be coupled in by means of friction-clutches which will serve to operate that unit. In the station there are two De Laval steam turbine-pumps, one of which is 55-h.p. 3,500 gal. per min., 43 ft. lift, and one 35-h.p. 2,000 gal. per min., 43 ft. lift. There is one duplex steam-pump for washing the filter sand. After the water is allowed to pass through the sand and gravel for about a month the sand becomes coated with sediment and it is necessary to shut off the water from this particular bed and remove the sediment which has collected from the surface, perhaps one inch thick, and take it to the cleaning-vat, where it is washed by means of the pump just referred to. The sand is allowed to dry and again used for filtration purposes.

The plant also contains one 55-h.p. lighting plant; two 132-h.p. Babcock and Wilcox boilers, with dutch oven furnaces. The steam turbines and pumps are placed below the floor, so as to make the plant very compact. The steam turbines exhaust into a Wheeler condenser—the water delivered by any of the pumps acting as cooling water. The condensed steam is delivered to a Cochrane feed-water heater by means of an Edwards air-pump, and the water from the feed-water heater is delivered to the boilers by means of a Knowles duplex outside-packed plunger-pump. After the water passes through the filtration beds a portion of it is forced into a main by the De Laval pumps, and it is estimated that the three units will handle 15,000,000 gal. water per 24 hours. The water company has spent an enormous amount of money endeavoring to make the water supply for the city of Denver as complete as possible.

contribute largely to the success of this important irrigation system.

The original plant of the Standard Consolidated Mines Co., built according to the recommendations of the consulting engineer, H. H. Nicholson, showed that a good saving could be effected by a simple concentration process and ALLIS-CHALMERS crushing rolls. The mill has a daily capacity of 100 tons, and will be in operation by the end of November. Those rolls are designed to crush 35,000 tons of ore per year.

THE STANDARD ELECTRICAL WORKS was the first of the burnt-out San Francisco electric firms to resume business in a permanent location, the Atlas Bldg., at 606 Mission St., San Francisco. They carry a full line of electrical supplies for mines, and are able to make prompt delivery from their warehouses. They are Pacific Coast agents for Simplex Electrical Co., insulated wires and cables; Simplex Electric Heating Co., electric heating apparatus; Electric Machinery Co., generators and motors; Mechanical Appliance Co., D. C. motors, small sizes; Century Electric Co., single-phase motors, A. C. ceiling fans; American Vibrator Co., electric vibrators; Triumph Electric Co., D. C. generators and motors; Warren Electric Mfg. Co., steam turbines and A. C. generators; Commercial Electric Co., two and three-phase induction motors; Jandus Electric Co., enclosed arc lamps and fan motors; Lafayette Electric Mfg. Co., Hornberger transformers; Duncan Electric Manufacturing Co., A. C. and D. C. wattmeters; Jewell Electric Instrument Co., portable and switchboard instruments; DeVau Telephone Manufacturing Co., telephones; California Incandescent Lamp Co., incandescent lamps. Their facilities for supplying mines are further displayed in their advertisement on page 51.

Editorial.

FIRST the earthquake and fire; then Schmitz and Ruef; lastly the Big Stick. Poor old San Francisco! When restless nature and degraded man, when the lowest and the highest unite to discipline her, what shall she do but murmur Bret Harte's lines

"Serene, indifferent to Fate,
Thou drawest all things, small or great."

HAVING REGARD to recent events, it is interesting to note that Cuba's export trade with the United States during the fiscal year just ended amounted to \$84,979,831, and her imports from this country to \$46,377,277. Sugar accounts for \$60,208,148 of the exports from the island and tobacco for \$17,474,269. The only mineral product specified is iron ore, to the amount of \$2,052,501, against which Cuba took \$1,801,586 in American coal.

THERE IS a movement afoot to establish a school of mines in Nevada county. This is one of the oldest and most progressive gold-mining districts in California, and if a local institution of this kind is to be established, no better locality could be chosen. It is possible that such a school could be conducted in friendly co-operation with the mining department of the University of California, at Berkeley, the idea being to give a practical course among the environments of actual mining, while on the other hand the students from Nevada county might visit Berkeley and listen to a special series of lectures on some other subject.

THE same daily paper that announced that there had been a competition in essays on 'The Ethics of the Modern Newspaper' at Stanford University, devoted a whole page to a fraudulent advertisement of shares in an invention, which, it was promised, would ensure a life income to the purchaser of stock. Ethics is a large word for such small business. Robbing the poor and deceiving the simple come within the meaning of graft, which our San Francisco papers pretend to be fighting, with wordy editorials and vain protestation.

THERE IS anxiety at Mt. Bischoff, the premier tin mine of the world. Advices from Tasmania state that the manager, Mr. H. W. F. Kayser, has been compelled to acknowledge his inability to maintain the present production and shares have fallen from £55 to £35. However, this grand mine has looked sick before and yet regained vigorous productiveness, so we shall hope that new orebodies may be discovered to compensate for the exhaustion of reserves.

WE sympathize with the movement for good roads and note, with pleasure, that the recent convention at Denver was well attended. The citizens of Colorado, led by Mr. Thomas F. Walsh, are endeavoring to secure the

legislative appointment of a State Highway Commission, the business of which will be the construction of a system of good roads. We hope it may become a fact, for a mountainous country like Colorado cannot be wholly served by railroads and anyone familiar with its less accessible localities knows how much there is of mineral for the miner and scenery for the traveler that is at present out of reach, simply because a burro trail is not yet the equivalent of a highway of civilization.

Progress in Cyanidation.

The article on 'Recent Improvements in the Cyanide Process' by Mr. F. L. Bosqui, will command attention, being written by one who is in the thick of current practice. Mr. Bosqui favors filtering machines of the Moore-Butters type and is inclined to consider, as Mr. Alfred James does, that filter-presses will shortly be relegated to the background. This appears open to doubt. Two large facts are against it, namely, the continued use of presses at Kalgoorlie and the successful improvements recently made by Mr. C. W. Merrill at the Homestake. From Kalgoorlie we hear good news of the Ridgway invention, a horizontal revolving automatic vacuum filter, but this machine has yet to be tried in the United States. At present, of all the sand leached at Kalgoorlie only a few thousand tons are treated by devices other than filter-presses. All the larger mines in the back country use them and the Ivanhoe is now erecting a new filter-press plant. Filter-pressing at Kalgoorlie now costs about 35 cents per ton, and leaves 12 to 15 per cent moisture in the cakes; it is believed locally that a new plant on a large scale could be operated for not more than 25 cents per ton. Of course, in regions where water costs nothing and the original slime is docile to treatment, the filtering machines will make a better comparison with presses. Meanwhile, Mr. Merrill's work is bound to encourage the advocates of the older method. He has enlarged its scope and simplified its details. With 24 filter-presses, each weighing 65 tons, and each of 26-ton capacity (as compared to the old 6-ton presses), he expects the total cost of treating slime to be not more than 25 cents per ton. The mills make 1,600 tons daily of this product, and 2,400 tons of sand. A test has been made on 6,000 tons of slime. In charging, he uses a pressure of 35 pounds; while leaching, 12 to 15 pounds; and to sluice with, a pressure of 65 pounds per square inch. Out of a slime containing 91 cents, he extracts 83 cents. Mr. Bosqui gives other details; those we quote are from Mr. Merrill himself. It is a remarkable fact, worthy of note, that after 28 years working, 35 per cent of the Homestake ore still comes from surface excavations. Another matter under trial is the use of zinc dust as against shaving; the former is gaining ground in America. We are informed that at the Waihi, treating 25,000 tons per month, it requires seven men continuously to clean the boxes, using zinc shaving; at the Homestake, treating 45,000 tons per month, only four men are employed a half-day, using zinc dust. In all these matters there is a constant effort to improve, and it is only by unprejudiced tests that the best method can be determined. On another

page, Mr. E. H. Nutter adds greatly to the value of our Discussion Department by a letter in which he compares the use of the Moore and Butters filters. Such first-hand information from practical men will be of service to all those who use cyanide in milling. We trust other friends will not hesitate to put their experiences on record, where it can be of general service.

Gambling in Mining Shares.

The craze for mining stocks has become a speculative debauch; someone will soon wake up with a head-ache, possibly a heart-ache, too. It is an everyday blunder to suppose that gambling in shares on the say-so of irresponsible people is 'mining;' it is no more mining than the funny business of the turf is horse-breeding. The affair of Dr. Lyman, the Goldfield consolidations, and the Nipissing episode all mark the beginning of a collapse in the trading of mining stocks of the purely speculative kind. Of the Nipissing episode there is not much to be said except that when people like the Guggenheims and Capt. De Lamar engage in a financial tussle it is best to give them plenty of room. For the public that bought Nipissing up to \$34.50 on the statement that the Guggenheims had bought a block of 400,000 shares at \$25 per share, we have much sympathy, but no respect. They came between the upper and nether millstones of two resourceful combinations and were ground exceeding fine. When Nipissing fell to \$14.50, it may have been due to an organized bear raid and many must have suffered, but what could they expect when they bought risky mining shares on a margin during a boom? The Guggenheims are being blamed for the fiasco and while they can technically disclaim any fault, the recent occurrence does indicate that any financial house that desires respectability must avoid such entanglements. How? Well, by preventing the premature announcement of a deal that is not consummated and of contradicting any statement that is calculated to mislead. The Dr. Lyman affair brought out the fact that one of the 'securities corporations' was the expression of financial activity on the part of a news bureau at Tonopah. They make history so fast in the new mining camps that bucket shops become trust companies and gamblers are metamorphosed into bankers almost while you wait. All of which only becomes manifest when the bubble has burst and its iridescent films fall like chunks of brick on the heads of the unwary. As to the Goldfield consolidation, it is safe to say that more money is lost in rich mines than in poor prospects. The four mines already consolidated are capitalized at \$50,000,000 and are selling at \$42,500,000. Does anyone realize the amount of ore required to justify such a price? The Company's circular states, that including prospective ore, "the future production from the now known ore-shoot" should be "at least \$30,000,000." Of this, on a favorable estimate, about \$20,000,000 may possibly be profit. To make good on a capitalization of \$50,000,000 there is required a gross production of \$65,000,000 to pay back the capital; with dividends at 10% and five years to return the capital, another \$25,000,000 of profit, or say, \$40,000,000 of ore is needed.

At least \$100,000,000 must be taken out of this group of mines in order to justify the capitalization. Nor do we say that it will not be done, but the proof is wanting, and very few people know what they are paying for when they take shares at their present valuation. Of course, they expect to unload upon the other fellow, but in the end the loss to the honest portion of the community and to legitimate mining is the difference between the inflated price and the true value. The purchase of the Combination mine for \$4,000,000 does not represent sound judgment; it may indicate a speculative spirit, some of which is always a useful factor in mining, but four millions for a mine that has paid only \$786,000 in the last 25 months and that is only 300 feet deep, looks like a gambler's throw. When Messrs. Winslow and Hubbard bought the prospect for \$75,000 they exhibited good judgment, and they have since profited by the speculative exuberance of their neighbors.

Cobalt and Goldfield are today the excuses for the two greatest gambling affairs on record. At Cobalt the mines already organized into companies represent a market value of \$200,000,000, while it is a fact that the entire output of the district since the first ore was shipped reaches only \$5,000,000. We do not deprecate an eager interest in mining, only the insane gamble that uses mining for an excuse. One of our contemporaries the other day expressed surprise at our depreciation of speculation in small-priced mining shares, because from its point of view any money that went into mining was so much to the good. The fallacy lies in the notion that buying paper certificates or playing with them, is mining; the fact is that in times of a boom like this the amount of actual work done underground in ratio to the financial operations based upon it, is humorously out of proportion. What is more, the mining profession suffers; boom mines need optimistic people not hampered by too sacred a regard for truth and the flotation of wild cats needs only the service of the wild-eyed among make-believe experts. In Nevada today there is many a promising young mining engineer who is being undone by the gambling fever, who makes his office a bucket shop and his technical training a lure for the ignorant. Another evidence of the barter of self-respect for quick gain is that of the mining engineers who permit the use of their portraits in the flamboyant advertisements of a mining prospectus and in disreputable newspapers. Two such cases have attracted our attention lately. Such performances are most regrettable. Real honest work is everywhere corrupted by the atmosphere of greed. It is all rubbish to speak of it as being to the advantage of this community to have a big stock boom long continued. The money that is made nefariously finds its way chiefly into the hands of those that are on the edge of the criminal class, to the kind of people that are today before the Grand Jury. Such money never builds a City or makes a community great. It is bathos to talk of the glories of the Comstock when reference is meant to the thievery and corruption of the boom days, forty years ago. We want to see Nevada as prominent in the mining world as it was then and we hope to see it as splendidly productive, but in Heaven's name let us have no repetition of

the dirty scheming that was an integral part of the Comstock story.

One feature only of the present boom is satisfactory and that is that while widespread and large in volume, it has not scaled the giddy heights of older performances. The Curb is deluged with stocks of newly organized companies operating at Cobalt, in Nevada, and in Mexico, but the loss will fall largely on gamblers and on lambs that know how it feels to be shorn. As soon as the capital of these and of other simpler folk is exhausted, the reaction will come, like a shower after a brilliant display of lightning. We may recall ancient history and state that at the end of the bonanza craze of 1875, the shares of the California mine receded 60 per cent in one week. Consolidated Virginia dropped from \$700 to \$500 per share; a few years later this stock sold at \$1.90 per share and California, which once soared to \$780, fell as low as \$1.25. In five years the mines that had stood on the market at \$393,000,000, were selling on the basis of \$7,000,000. In 1868 Alpha sold at \$1,570 and in 1870 it fell to \$3 per share; during 1872 Belcher sold as high as \$1,525 and as low as \$1.50; later still it brought only 25 cents per share. In 1881 New York had a mining boom of its own and it lasted as long as capital was poured in. Then it went to pieces. The Leadville shares suffered most; Little Chief was selling at \$18 and eventually was quoted at a few cents; Little Pittsburgh rose to \$45 and the mine was sold for debt not long afterward. These facts should be enough to warn the inexperienced, but warnings as a rule are like the ointment that went down Aaron's beard, even unto the skirts of his garment—simply a waste of good material. Unfortunately many people never get beyond this infantile stage of mining; becoming shorn by the bears, they go bleating into a cold world and protest that they have had enough of it. As a matter of fact, the vagaries of the stock exchanges are related to the industry of mining as the betting on the racecourse is to the ownership of a good horse, the breeding of fine animals, or the health-giving exercise of riding across country.

THE PLAINT of the underpaid professor is heard in the land. His salary remains fixed, while the cost of the necessities of life, not to mention its luxuries, mount higher and higher. Professors have no union, they are unable to keep out apprentices or to excommunicate those who are willing to work on a stipend even smaller than their own. In San Francisco the hod-carrier gets a bigger wage than the man who is training the youth of California at her State University. It is a blot on civilization; it is a joke on learning. But there is another meaning, less obvious, but more true. Men of culture are willing to pursue avocations that afford but a small financial return, because they love their labor and make it part of their life. The hod-carrier works to eat and sleep, the usefulness of the building he helps to erect is no part of his purpose; but to the professor the routine of daily work is illuminated by the sense of doing something that counts, and is alleviated by studies that enlarge his horizon, stimulate his imagination, and make him feel that everything in life is not measured by the unit of the dollar. Man does not live by bread alone.

Special Correspondence.

London.

Kaffir Market Dull.—Other Descriptions Active.—Excitement in Deep Leads.—Activity in Siberian Ventures.—Another Cornish Flotation.—The Dolores Meeting.—Complaint As to Transmission of News From American Managed Mines—Oroville Dredging.

The spotty nature of the market for mining shares, remarks *The Globe*, is revealed by yesterday's making-up list. While the South African section, apart from diamond descriptions, has been almost lifeless, several other departments have come prominently forward, and the bulls of a number of shares which a short time ago were lumped together as miscellaneous descriptions, have certainly good cause for congratulation. Unfortunately, the outlook for Kaffirs shows no signs of clearing, and even if the Letters Patent for the new Legislature are granted within the promised period there still remains the uncertainty as to how the elections in the Transvaal will result. It is to departments other than South African that one has to look for the biggest movements. In fact, here and there the gains are almost sensational, as quite a boom is in progress in Siberians, Barriers, Deep Leads, and Coppers. The first-named provide the feature of the past account, Siberian Proprietary having risen as much as £5½, from 9 to 14½. Siberian Syndicates have put on 1½, and Orsk Goldfields nearly ¾. In Broken Hill and Deep Lead descriptions some substantial gains have resulted from the active buying that has been in progress during the fortnight. Australian Commonwealth Trusts, which are now fully paid, carried over yesterday at 3½, as compared with 1½ premium on the last occasion, which represents an improvement of 1½. Broken Hill Proprietary and Block 10 have gained 1½ and ½ respectively, and Loddon Valleys, 10 shillings.

Deep Lead stockholders have been kept on the *qui vive* this week. Two cablegrams have appeared in the press, the first to cheer their spirits, the second less inspiring. To start with, the news was to the effect that "No. 2 rise, wash half-way across the face, just at point laths. Washed 2 ft. by 2 ft. by 1 in. ground, ¾ dwt. nice sample gold. Cannot estimate the value of wash until we get more of face. About 1 in. sand on the bedrock. Tight wash above. D. H. Brown at the mine; (he has) telegraphed prospects decidedly encouraging. It is not possible sample fairly until (bedrock) dips. Caution must be exercised in estimation of values. We are now opening up (with) all speed." The market seems to have found some difficulty in understanding this cablegram. One dealer is reported to have sat up half the night endeavoring to get at its meaning, but went to bed without having succeeded. There were others, however, who imagined they detected a bull point and proceeded on the strength of their superior insight to acquire some shares, or induce their brokers to do so for them, to 'carry over' for the rise. It came, but worse luck! the second cablegram gave the bears a look in. Here it is: "No. 2 rise—Have cleaned up 4 ft. by 3 ft. by 6 in.; obtained 2½ dwt. of gold. Cement in wash shows gold. Owing to looseness wash, flow of water too strong; have ceased operations this point for the present. Pushing on drive turning north on No. 2 rise to enter into different points. Pushing on other points highest possible speed." Office note: "The company's engineers state that, in their opinion, no importance is to be attached to the flow of water from the wash on the first entrance, as this is usual, and they anticipate it will only require a few days for the flow of water to decrease to a point at which work

can be resumed." Speculators may now be assumed to be sitting up burning the midnight oil in making forecasts as to how many days will pass before the decrease of water and the re-working of the golden wash will enable them to close their bargains at a profit. The Loddon Deep Leads (Victoria) has not yet reached such an exciting stage in its history. The directors have a more prosaic duty to perform, and in submitting their second annual report and the accounts of the company for the period ending October 31, 1906, they are in the happy position of being able to inform the shareholders that arrangements have been made to finance the company without calling upon them for further assistance, and they are confident as to the early success of the company, for the following reasons:—" (1) We have proved that there is a lead on our property, that it consists of boulders, water-worn pebbles, etc., considered and reported on as of a very favorable nature, and also that it is gold-bearing. The finding of this gold on the western edge of the lead is considered very promising, as the gold, as a rule, hugs the eastern side. (2) The consensus of opinion from the shallow depth of drift, the nature of surrounding country, is that we shall not have a very great volume of water to contend with. (3) By strata passed through from 207 to 213 ft. and again at 227 ft. it has been proved that a strong network of quartz leaders was passing through the shaft, the stone is hard and a darkish color, and by assay shows a trace of gold."

The latest Siberian prospectus is that of the Kluchi Gold Mines Ltd., the first subsidiary of the Nerchinsk Co. The capital of the new venture is £280,000 in £1 shares, of which 115,000 have been underwritten and are offered at par. Shareholders in H. A. Syndicate, Siberian Mines, and Nerchinsk, will have the preference in allotment. The prospectus states that the Company has been formed to acquire the gold mining rights of the Mount Kluchi block in the eastern part of the Nerchinsk mining district of Siberia. Of the considerable expenditure that has already taken place, the Company will have the benefit. It is stated to be no less than £54,000 in development work and the purchase of machinery. The report of Pearce, Kingston, & Browne, consulting engineers to the Nerchinsk Co., appears in the prospectus. It anticipates that within a few months, the present mills, capable of crushing 100 tons per day, will be in full operation, and that the profit will amount approximately to £40,000 per annum, even should the contemplated increase of power not be made.

Not to be outstripped in flotations, Cornwall also appears with a prospectus this week. The Wheal Commerce Tin Mine, Ltd., is the latest candidate for public favor. It is a producing tin mine, the past workings of which "indicate present value and possible future profits." The capital is £50,000 in £1 shares, of which 44,000 are offered for subscription at par—25,000 being reserved for working capital. The Company proposes to acquire the Commerce tin mine, in the parish of St. Ewe, 3½ miles from St. Austell, along with the plant and machinery which include 10 heads of Californian stamps and 14 heads of Cornish stamps, while capital is provided for adding 40 more stamps. The property consists of about 600 acres, and is held on favorable terms for 21 years from June, 1900. Work has been done upon two main lodes, the Vertical and the Commerce, which have been traced for nearly ¾ mile, and there are also other lodes. The shaft on the Vertical lode is down 320 ft., and a sample from the bottom working assayed 40 lb. black tin per ton. This lode, Mr. Harold L. Twite, who has reported upon the property, recommends should be vigorously pushed forward, which will, "if present width be maintained," yield 28,000 tons of ore. Tin to the amount of £7,272 has already been sold, as the result of

past "experimental work." The average value is reported to have been 30 lb. black tin per ton. The total working costs are estimated at 13s. 6d. per ton. It is calculated that with an output of 50 tons a day, and allowing 15s. per ton for working costs, the credit balance will be £12,185, which would allow of a dividend of 20% per annum upon the capital. These estimates are stated to be based upon black tin at £100 per ton, and also presumably on the assumption that the present width of the lode is maintained. The following is a summary of the fortnightly tin 'ticketing' at Redruth:

Amount of tin sold.....	243 tons.		
	£	s.	d.
Total realized.....	27,459	7	6
Metal standard.....	195	12	6
Black tin average.....	113	0	0
Doleath, 70 tons.....	8,314	17	6
Carn Brea and Tincroft, 33 tons.....	3,334	12	6
Basset United, 31½ tons.....	3,370	2	6
East Pool and Agar United, 25 tons.....	2,750	7	6
Grenville United, 25 tons.....	2,816	10	0
West Kitty, 16 tons.....	1,858	0	0
Clitters United, 15 tons.....	1,753	2	6
Levant, 15 tons.....	1,716	7	6
Wheal Kitty and Penhalls United, 4 tons.....	465	0	0
Geavor, 3 tons.....	297	7	6
Wheal Jane, 2 tons.....	230	5	0
Mulberry, 2 tons.....	199	10	0
Baillswidden, 1 ton.....	106	2	6
Birch Tor and Vuller, 1 ton.....	129	15	0
Tehidy Tin Streams, 1 ton.....	78	7	6

It is expected that within a few weeks South Crofty will be added to the ticketing list with the first parcel of black tin after treatment through its new magnetic separator. Good progress is reported at Condurrow United. The engine-house is up and the roof is in course of construction. A head-gear 60 ft. high and a capstan have been erected. One boiler is in position and another is being lifted in. At the adit the first cistern has been constructed and the pitwork from that point to the surface almost completed. As soon as the engine has been installed, pumping will commence.

At the second annual meeting of Dolores Ltd. the chairman referred with regret to the retirement of Messrs. Farish and McCarty as consulting engineers and to the appointment of George A. Schroter—"a mining engineer of the highest repute"—to fill the vacancy. Further capital outlay would have to be made, the chairman said, amounting to £20,000, the largest items being for additions and improvements to the mill. He reminded the stockholders that the capital expenditure already made had absorbed the original working capital of £30,000 and also the £50,000 net profit on the working of the mine. Hence the necessity for the proposed new capital of £70,000 of which £66,000 would be issued forthwith at the price of \$5 per £1 share. The new shares would be offered *pro-rata* to the shareholders and the subscription list would be closed on December 31. Referring to the new management, the chairman stated that Mr. Schroter has appointed Mr. H. Paul as manager. Mr. Paul assisted Mr. Schroter when he was at the mine three years ago, and he practically had charge of the mine for the first six months, and in a letter to the president Mr. Schroter says he considers everything is progressing well at Dolores, and that the mine is in good shape and everything well systematized.

As to ore reserves: Mr. Schroter's estimate of net value contained in ore, tailing, and dump, was \$1,200,000. The chairman remarked that his estimate of £240,000 net for ore reserves did not seem to tally with former estimates; for in 1903 he estimated the net value of ore reserves at £290,000, which ought to be still maintained if Mr. Farish is right in his opinion that developments during the past year have equalled in net value the profit taken out of the ore. With regard to developments on the bottom, or 4th level, it seems the

vein was struck by a tunnel from the bottom of the shaft about 28 ft. to the west, showing very low values; but in driving north on the vein during the past few weeks the values had increased to \$30, and, judging from the 3rd level, the values should further increase going north. As to the development by cross-cut No. 4, at a point 186 ft. north from the shaft a slight fault was encountered, and beyond this, about 130 ft. was driven through almost barren ground, when ore was again encountered, showing values for about 30 ft. of \$25.

Cross-cut No. 4 was started to the west about 50 ft. north of the fault, and has struck \$160 ore 2 ft. thick with ore in forebreast assaying \$68. A director, in seconding the adopting of the report and accounts, said the position of the mine was, in his opinion, more satisfactory than it has been for some time past, and he understood from the American board, with whom he had been in communication, that the Company would be dividend-paying within two or three months from now. An account of the meeting would be incomplete without some notice of a shareholder's remarks on a feature of American managed mines on the London market. He said he wished to add a word or two with regard to the reception of news in London from the American directors. Some of the shareholders in this Company were also interested in another Mexican mining company where there had been considerable delay in the transmission of rather important news relating to developments at the mine. That delay appeared to arise through considerable time being required for the consulting engineer to make his report to the directors of the American company, for them to carefully consider the result of that report, and then finally to cable the same to London. During that interval any advantage that might accrue to an English shareholder was likely to be entirely lost by its premature disclosure on the American market, and he had been very much interested in listening to what the chairman had stated regarding the steps which he had taken when in New York to ensure the prompt receipt of all information relating to developments and other important news from the mine on the London Stock Exchange; and he certainly hoped that the directors of the Dolores would set an example in that respect, which he was sure would be very gratefully received by the shareholders of the company.

The chairman said he could assure the shareholders that there was nothing he felt more strongly about than the importance of their receiving on this side the earliest possible information and letting the shareholders and the public have the benefit of it. The board had arrived at a distinct understanding with Mr. Farish that all cables and his reports to the American board should be made in duplicate and be sent to London at the same time. He expected Mr. Schroter would carry out the same system.

Stockholders in Oroville Dredging have been notified that the gross returns week ended November 12 amounted to \$25,000, bringing up the total to \$949,000, since the Company started on August 1, 1905. Also that 12 dredgers are now in operation on the following properties, namely: 3 on the Boston & California, 4 on the Boston & Oroville, 3 on the Exploration, and 2 on the Bear River. The Directors have declared a fifth quarterly dividend of 12½c. per share, payable at Boston on December 29 to shareholders of record on December 15. Mr. Weatherbe's letter on 'Gold Dredging' in your issue of November 3, should be read by all stockholders in Oroville Dredging Ltd. for *inter alia*, the information it conveys as to average recoverable values, working cost, and net annual profit.

Butte, Montana.

Output of Copper in November.—A Decrease.—East Butte Affairs.—

A Favorable Report.—A Squabble Over a Title.—Explorations by the Reins Co.—Alliance Strikes it Rich.—Operations of Butte Men in Arizona and Idaho.

The copper output of the Butte district in November amounted to 26,600,500 lb., a decrease of 2,292,740 lb. from the previous calendar month, due chiefly to the fact that the Parrot company has dropped its production to about 200 tons per day while extensive new orebodies are being opened, and the Original company, always uncertain in its output, is mining in a very lean zone at present, and a number of the mines were closed for a day or two on account of cold weather. The different companies contributed to the November output as follow:

Company.	Tons of ore.	Pounds of copper.
Boston & Montana.....	90,000	6,840,000
Anaconda.....	102,000	7,446,000
Butte & Boston.....	17,400	1,218,000
Washoe.....	15,000	1,050,000
Parrot.....	6,000	348,000
Trenton.....	17,400	1,183,200
North Butte.....	30,000	3,540,000
Butte Coalition.....	28,500	2,052,000
Original.....	18,000	1,080,000
East Butte.....	6,750	607,500
Pittsburgh & Montana.....	4,500	396,000
Miscellaneous.....	12,000	840,000
Total.....	347,550	26,600,500

The daily output of ore and the average yield per ton in copper were as follows:

Company.	Tons per day.	Pounds of copper per ton.
Boston & Montana.....	3,000	76
Anaconda.....	3,400	73
Butte & Boston.....	580	70
Washoe.....	500	70
Parrot.....	200	58
Trenton.....	580	68
North Butte.....	1,000	118
Butte Coalition.....	950	72
Original.....	600	60
East Butte.....	225	90
Pittsburgh & Montana.....	150	88
Miscellaneous.....	400	70
Total.....	11,585	

Frank H. Probert of Los Angeles, geologist and mining expert for Thomas F. Cole and the General Electric Co., has been in Butte for several weeks examining the mines of the East Butte Copper Co. and other properties. Mr. Probert has made a favorable report on the East Butte and strongly recommends the erection of a 500-ton concentrator for the treatment of the company's low-grade ore. He reports that in No. 11 mine, known as the Yankee Boy, he found at a depth of 225 ft. a vein 52 ft. wide that will average 4% copper. In No. 1 shaft, in the south cross-cut, he found a vein 15 ft. wide a short distance from the shaft, and another of equal width north of the shaft. Much of the ore in those two veins is first-class. The ore from the 400-ft. level up to the 200 is practically undisturbed, and Mr. Probert suggests that good judgment and economy make it advisable to mine this ore under the present high copper market, rather than confine work entirely to development. Mining and development could be carried on together. A 500-ton concentrator in two units, could be built for \$250,000. Mr. Probert also recommends that lessees be permitted to continue work on the levels above the 200, it having been the intention of the company to stop all leases on the first of the year. He thinks the lessees can mine that portion of the property more economically than the company, and that the 25% royalty received is a good item. There are also two small concentrators on the company's ground, operated by lessees, paying the company 25% royalty, and in addition to that a large precipitating plant is operated by others who are saving a lot of copper from the water and tailing deposits on the company's ground, the company

receiving 25% of the copper so recovered. The main shaft of the East Butte has reached a depth of 625 ft., and a station is being cut at the 600-ft. point, from which cross-cuts will again be run north and south. No indication of the iron zone that has been found in some of the other mines in that locality near the surface, has yet been encountered, and mining men generally now express the opinion that the zone will not be found at all there. At 400 ft. where the veins have been cut they are larger than near the surface and just as rich in copper. Mr. Probert paid a compliment to the management of the mines by Patrick Wall, general manager of the company and one of the most experienced mining men in Butte, and to the business management of the company's affairs by Mr. F. M. Sullivan. W. A. Paine, one of the principal stockholders of the East Butte, purchased 10,000 shares of the treasury stock at the market price, and the money will be employed to carry out plans of betterment and to pay for a large tract of land which the company acquired sometime ago, and which Mr. Probert considers a good investment, as in his opinion some of Butte's biggest copper veins will be found in that portion of the district. The lessees in the East Butte mines in November paid about \$12,000 in royalties, that being \$4,000 more than they paid the month previous.

The Anaconda Co., which is operating the Gallatin and J. I. C. shafts just west of the East Butte, has secured from the District Court an injunction to prevent the owners of the May quartz claim from mining in that ground pending a final determination of the controversy between placer and lode titles. The Anaconda Co. owns under a placer location and patent and has been mining the quartz for some time, the contention being that the quartz was not known to exist in the ground until after the issuance of the placer patent. The owners and locators of the May have contended that the quartz veins were known at the time the placer was located and that therefore the veins are excluded from the placer patent. The District Court, on the preliminary hearing, held in favor of the Anaconda Co. The latter mines about 400 tons of ore per day from the two shafts. The owners of the May also did some mining on an adjoining piece of ground until they were stopped by the injunction.

The Reins Copper Co. has purchased the Ella Mining Co.'s property, a fractional claim lying north of and adjoining the Combination mine, which the Reins Co. is exploring. Colonel Guffy, of Pittsburgh, has been the principal financial backer of the Reins Co. and has put several big fortunes into the ground in an effort to find the eastern extension of the big Leonard vein of the Boston & Montana. He has paid \$240,000 more for the Ella. A cross-cut run north from the 1,200-ft. station of the Combination has about reached the Ella south side-line, and will now be continued into the Ella ground, and perhaps through it. There is a shaft 800 ft. deep on the Ella, and some years ago a considerable quantity of silver ore was mined from it.

The Alliance Copper Co. has cut an 8-ft. vein of copper ore 50 ft. east of the shaft at a depth of 200 ft.; it carries 10.8% copper, and 82 oz. silver per ton. It is claimed that three feet of the vein will average 20% copper. The shaft on the Alliance ground was sunk jointly by the Alliance and Farrell copper companies, their territory adjoining. The vein cut in the Alliance ground goes through the Farrell also. This is in the southeastern portion of the Butte district, and west of the East Butte mines.—The shaft of the Colusa-Leonard Extension Co. has reached a depth of 75 ft., but work on it has been stopped pending the installation of a new engine and boilers, which are now being placed.—The face of the cross-cut which the Original Co. is driving south from the 1,800-ft. station for the Davis-Daly Estates Co.,

is in more than 1,000 ft., but so far only a few stringers of ore have been encountered. The company expects, however, to cut a larger vein with a further distance of about 100 ft. Work at the other mines of the company is progressing satisfactorily, but no ore in commercial quantities has been found in any of them.

Butte men are interested in a new company operating in the Mullan district in Idaho, called the Boulder Creek Mining Co. Its principal claim is the Central, situated less than a mile from the town of Mullan. Two adits are being driven as drifts on the vein. One adit is 400 ft. long and in ore to the face. The other adit is also in ore and 140 ft. long. Ore taken out in running the adits assays from 10 to 50% lead, and carries some silver and copper. W. F. Edwards, a mining expert who examined the property, says "it is the best prospect known in the Cœur d'Alene mining region." — Reports from the mine of the Butte & Arizona Co., in Arizona, continue to arouse enthusiasm among the officers and stockholders in Butte. W. W. Adams, who has just returned from the mine, says the adit is progressing rapidly, and the face of the opening is going toward the immense surface croppings, and will be reached in another 200 ft. Each foot of adit gives a foot in depth. The adit is on a vein and there is ore all the way. Cross-cuts are being driven on both sides of the adit. In the opinion of Mr. Adams, the mine will develop into an immense copper producer.

Toronto, Canada.

November Shipments.—The Nipissing Affair.—The Question of Titles.—Necessity for Better Security.—Phenomenal Ore in the Right of Way.—Reclaiming a Lake.—Other Strikes.—The Laurentian Mine.—Discoveries of Iron Deposits.

Shipments of Cobalt ore over the Temiskaming & Northern Ontario Railway for the month of November amounted to upward of 724 tons, as compared with 1,120 tons for October. The amount shipped from each mine was as follows, fractions being omitted:

La Rose.....	247 tons
Buffalo.....	140 "
Contagas.....	120 "
Nipissing.....	99 "
Trethewey.....	53 "
Foster.....	23 "
Nova Scotia.....	23 "
Green-Meehan.....	17 "

The flurry in Nipissing and other Cobalt stocks during the earlier part of the week caused by the refusal of the Guggenheims of New York to complete the deal for the purchase of 400,000 shares of Nipissing stock, on the ground that they had been refused sufficient time to make enquiry into the title, rumors as to the insecurity of which had been afloat, has brought the question as to the validity of mining titles prominently forward. As far as the Nipissing properties are concerned, J. J. Foy, Provisional Attorney General, has made an official statement that he was not aware of any protest having been presented to the Government as to the company's title or any intended application for a fiat to permit a suit to be entered. This is well enough as far as it goes, but at the same time it is hardly the absolute security naturally required in a deal involving ten million dollars. The fact is that the situation as regards stability of titles generally is in condition far from satisfactory to the large investor. There is any amount of litigation now pending in connection with Cobalt properties. As the law now stands after the title has passed from the Crown, anyone seeking to impugn it or set up a counter-claim on the ground of fraud or misrepresentation must first obtain a fiat—that is, the consent of the Attorney General to bring an action. This practically places at the mercy of the Government many of the mining enterprises of Cobalt,

especially those whose title dates back to the earlier days of the camp, when there was much irregularity and not a little downright fraud in making locations. Last summer the White Silver Mining Co. had their leases, covering about 120 acres, canceled, on the ground of fraudulent affidavits of discovery by the locators, and quite recently the owners of the O'Brien mine, after protracted litigation, were glad to secure their title by undertaking to pay a 25% royalty to the Government on their output. With these instances before them, it is hardly a matter for surprise that shrewd investors should hesitate before placing themselves in a position to be held up either by possible claimants or by the Provincial Government. Mining men are loud in their demands for some change by which an indefeasible title can be secured, which will be more satisfactory, to outsiders at least, than a cabinet minister's bland assurance that so far as he knows, no one is assailing it. The question is likely to have a prominent place during the coming session of the Provincial Legislature.

At the Right of Way mine, Cobalt, on December 1,

Map of Part of British Columbia.

seven men with drills and shovels took out about four tons of ore running from 2,000 to 6,000 oz. silver per ton and valued at over \$8,000. The work was done on the continuation of the Timmins vein.—The Peterson Lake Co. has almost completed the lowering of the outlet of the lake, which will reduce the level about 15 ft. and reclaim some 50 acres of the bed. The company is now sinking a shaft at the water's edge on the continuation of the Nova Scotia mine vein.—A find of native silver has been made on the Gillies Silver Mining Co.'s property. This is not the Gillies Limit Government mine.—At the Morrison mine a vein two feet wide has been uncovered. A shaft 10 ft. deep has been sunk showing ore rich in cobalt.—Stripping to the extent of 2,000 ft. has been done at the Green-Meehan mine.—Edward C. Davis and George L. Walker, both of Boston, and representing large financial interests, were among recent visitors to the Cobalt camp.—Last week a visit of inspection to the Laurentian gold mine in the Manitou Lake district was paid by a party of prominent mining men and financiers, including Anthony Blum, principal owner of the mine, of Boston, Hugo Von Hagen, John H. Banks, G. A. Vigouroux, and M. E. Downs, of New York, and Prof. F. Hille, of Port Arthur, Ontario.

A find of magnetite iron ore has been made in Wisner

township, which immediately adjoins Hutton township, in which the Moose Mountain iron ore deposits, now being tapped by the extension of the Canadian Northern Ontario Railway are located. It is regarded as probably an extension of the Moose Mountain formation.—The iron ore deposit at L'Amable in the Hastings county mineral region has been tested by diamond drilling and found to be 150 ft. deep.

H. P. Bell, a British Columbia engineer, has submitted a report to the Canadian Department of Railways & Canals as to the feasibility and cost of building a bridge from the British Columbia mainland to Vancouver Island. He says that the work would be of a formidable character and would cost at least \$35,000,000. By taking advantage of the Valdes islands the distance could be spanned by seven bridges of about 1,200 ft. each, but the channels are of immense depth and the tides rapid, and the islands being rocky, would prove difficult for railway laying. The bridges would have to be 150 ft. above the sea-level. The report is regarded as conclusive against any such undertaking for many years to come.

A new silver field has been discovered as the result of active prospecting in the Laurentian range, tributary to Montreal. The deposit consists of silver, galena, and lead, the silver, according to report, assaying high. The statement as to discoveries having been made, exciting widespread interest in the locality, is confirmed by L. O. Armstrong, colonization agent of the Canadian Pacific Railway, who has just returned from the district.

Salt Lake City, Utah.

Numerous Arrests at Instance of Government.—Coal Lands Enquiry.—Newhouse and Heinze Active.—Daly-Judge Declares Dividend.—Shipments From Tintic.—Local Stock Sales.

Somewhat of a sensation was sprung by the Federal grand jury last week by bringing indictments against several persons more or less prominent in railroad and coal-mining affairs, the action taken being the result of the investigation conducted recently in this City by the Interstate Commerce Commission. Everet Buckingham, general superintendent of the Oregon Short Line railroad, the Union Pacific Coal, Union Pacific, and Oregon Short Line railroad companies are charged with violations of the Interstate Commerce law and one instance of this is cited in the case of D. J. Sharp, a former well-known coal-dealer of Salt Lake. Because Mr. Sharp chose to sell fuel to his customers during the past summer at 25 cents under the usual rate—notwithstanding that the railroads had granted dealers a 25-cent cut in summer rates, he was refused more coal and was forced to retire from business. H. G. Williams, general manager of the Utah Fuel Co., James M. Moore, general Western sales agent of the Union Pacific Coal Co.; Robert Forrester, geologist and agent of the Utah Fuel Co.; William D. Foster, chief clerk in the office of Mr. Forrester; Elroy M. Clark, a Denver attorney for the Utah Fuel Co.; Alexander H. Cowie, chief clerk in the office of the vice-president of the Utah Fuel Co.; George A. Moore to secure dummies to locate land for the Utah Fuel Co., and the Utah Fuel Co. are charged with the crime of conspiracy to defraud the United States Government in unlawfully obtaining title to coal-lands; while Thomas A. Moore and Theo. Schulte must stand trial for perjury in the Utah Fuel land cases. Nearly all the defendants have been arrested and are out on bonds awaiting trial before Judge Marshall of the United States Circuit Court, in April next. It has been charged by agents of the Government that some of the best mines operated by the Utah Fuel Co. are located on lands obtained through fraud.

Samuel Newhouse has acquired a large interest in the property of the Ohio Kentucky Mining Co., at Pioche, Nev., and has been elected president of that corporation.—The taking over of a control of the Ohio Copper mine in Bingham by F. Augustus Heinze means the building of a mill for that property in the near future. Already, W. A. Kidney, metallurgist in the employ of Mr. Heinze, is working on the proposition. It is believed that a plant with capacity for the treatment of at least 2,000 tons of ore per day will be built.

The directors of the Daly-Judge Mining Co., of Park City, are scheduled to meet in a few days for the purpose of giving consideration to the posting of the initial dividend of that company, which will probably be a quarterly distribution of 45c. per share, or \$135,000.—A strike of considerable importance has been reported in the Odin mine at Park City. The find was made in the main adit at a distance of about 1,000 ft. from the portal.—The Nelson-Queen is a new shipping mine in the Elkhorn district, near Park City. Ore brought to the Salt Lake market last week netted \$45 per ton.

It has been announced that the breaking of ground for the new smelter of the Tintic Smelting Co., will begin soon after the first of the year.—The ore shipments from the Tintic mining district last month amounted to 154 carloads, the contributing mines and amounts being: Ajax, 3; Beck Tunnel, 10; Black Jack, 2; Bullion Beck, 11; Carisa 8; Centennial Eureka, 37; Eagle & Blue Bell, 8; Eureka Hill, 7; Gemini, 5; Godiva, 2; Grand Central 10; Mammoth, 18; May Day, 2; Scranton, 6; Tintic Iron, 14; Uncle Sam, 6; Victoria, 1; Yankee Con., 5 carloads.—Last week's sales on the floor of the Salt Lake Stock & Mining Exchange amounted to the transfer of 222,943 shares of stocks for \$220,495.

Bisbee, Arizona.

An Important Discovery in the Denn-Arizona Mine.

By Telegraph.—One of the most encouraging strikes ever made in this region was made on the property of the Denn-Arizona Mining Co., situated in the Warren mining district, yesterday, and at the present time it has

Arizona and Northern Sonora.

reached a stage of development where it is safe to say that a permanent orebody has been found. The great significance in the finding of this orebody in the Denn-Arizona ground lies in the fact that up to a short time ago most prominent mining authorities who have ever

visited Bisbee and the surrounding country have stated that copper ore would never be found north of the cañon where the town is situated, and an imaginary line called the Dividend fault has hitherto been regarded as the boundary for all big producers. The Denn-Arizona Co. was organized a little over a year ago, and against the advice of many authorities work has been steadily prosecuted. The property comprises 13 claims, and lies immediately north of the Junction property, which was lately absorbent by the Cole interests. At the present time the shaft on the Denn-Arizona property has been sunk to a depth of 1,100 ft., and at the 1,100-ft. level a drift was started; when the drift had been opened up for about 600 ft., the management decided to run a cross-cut to diamond-drill bore, and accordingly turned south. Yesterday morning the cross-cut had been driven 223 ft., when a round of shots opened up full face of 6% oxide and carbonate ore. At present the cross-cut has been driven through 14 ft. of ore and at every round of shots the average percentage of copper has increased. The management states that the sample assayed went a fraction over 28% in copper, and estimated that the ore would average 12% at least. The importance of this strike to the Warren district can be realized to some extent when one knows that hundreds of claims have been located north of the Dividend fault, and have not been developed because everyone was awaiting the outcome of the Denn-Arizona Co.'s explorations. The Cochise Development Co., the Warren Realty & Development Co., and the American Saginaw Co. have been also doing extensive development work north of the Dividend fault, but up to the present time they have found no permanent orebody, although well-grounded rumors state that a large body of high-grade ore was penetrated by the diamond drill on the Warren property, but the management will not give any statement in regard to this matter. The find at the Denn-Arizona has worked the stock up 12 points and higher prices are expected.

Goldfield, Nevada.

Many Rich Strikes.—The New Camp at Wonder.—Excellent Discoveries.—Improved Prospects at Manhattan.—Lot-Jumping at Goldfield.

Goldfield holds the centre of the stage at the present time, but while many rich strikes are being made, establishing this camp as one of the greatest in the world, the smaller camps are trying to develop another such goldfield, and with prospects of success. Among the more prominent outside mining camps is Wonder, situated but a short distance from Fairview. Many rich strikes have been made, and everyone visiting the locality returns with the tidings that Wonder will surely make another Goldfield. On the Nevada Wonder, the original discovery, ore is being taken that will assay better than \$600 per ton in gold clear across a 12-ft. vein. On the 150-ft. level ore is being taken that assays \$10,000 per ton. Shipping ore of great value, is being sacked as fast as men and money can take it from the ground, and no sorting is done. On the Mae Wonder property, lying between the Nevada Wonder and Joe Wonder, a large vein has been uncovered, returning assays better than \$200 per ton in gold. This rich deposit was broken into in doing the location work on the property, the vein not being exposed at the surface. On the Lucky Joe and Arthur R. claims of the Joe Wonder Mining Co., three or four veins have been opened, giving assays from \$50 to \$200 per ton, and development work is being pushed with great rapidity. The rich vein of the Nevada Wonder trends toward and through this property, and the management is hard at work opening up its rich veins. The showing to date is exceptionally flattering. Again, on the Daisy Wonder, rich ore has been dis-

closed, and, in fact, no less than 30 properties in the district are shipping ore. The ore is strictly free milling, and some of the finest specimens ever seen in the State were taken from the workings at Wonder.

Some excellent strikes in the Manhattan district have caused a stir in mining circles at that point. The finding of rich ore on the 200-ft. level of the Manhattan Consolidated, coupled with the strikes on the Independence, Paymaster, Giant, Original Manhattan, and Manhattan Nevada, has started all local stocks on the upward path, and it is predicted that a great boom will strike Manhattan before spring. The Manhattan Consolidated has 30 ft. of ore that will run better than \$40 per ton, while about two and one-half feet will assay over \$300. At a distance of 270 ft. in the tunnel on the Georgey group of the Manhattan Nevada Gold Mines Co. at Central, a regular vein has been encountered, which is 14 ft. between walls, and assaying better than \$10. This vein is strong, cutting the formation at right angles, and carrying every indication of permanency. It is the intention of the management to drive on it as well as to sink a winze to explore the ground and look for a high-grade orebody, as the character of the mineral is identical with that of the Consolidated, and the assays are even higher than those of the Consolidated when ore was first struck. In addition, this company is running a cross-cut from the bottom of an 80-ft. shaft, and the face is all in ore of good milling grade. East Manhattan is excited over an offer of a large amount, made by an Eastern syndicate, for the control of the Toquima Copper Co., the Bonanza Copper Co., and the Ralston Valley Gold & Copper Co. These three companies are forging to the front, and have large bodies of high-grade copper ore blocked out.

A misconstruction of a Federal Land Office decision is apparently responsible for an epidemic of lot-jumping at Goldfield, a sporadic outbreak of that instinct for plunder latent among the riff-raff of every camp. Phenix, a thrifty individual, not the thriving Arizona city, located ground between Goldfield and Columbia a few years ago as a placer. He then platted the land, and sold lots for building purposes. Squatters settled upon the tract, and the differences between Phenix and these other enterprising persons were taken into court, the Land Department being finally petitioned through the District Court to enter the land as a townsite, upon the assertion that the location was not being used for placer mining, but for real estate speculation. According to rumor the Court is about to receive instructions to enter the application of the squatters, and prepare to complete the procedure of establishing a townsite upon the land in dispute. The publication of this alleged action on the part of the Interior Department was a signal for a general campaign of lot-jumping, not only upon what remained vacant of the Phenix Addition, but also well within the business quarter of Goldfield, many of the most valuable lots in town being jumped, and signs erected claiming squatters' rights, under the delusion, presumably, that the Government order embraced all placer ground in the district, including the Goldfield placer upon which the main portion of the town is situated. The fact that a consideration has passed in the transfer of every lot in the Goldfield townsite, and that much of this real estate has changed hands a number of times at enhanced figures, had no deterrent effect upon this form of "enterprise without outlay." While there is probably no reason for anxiety on the part of those owning improved property at Goldfield, the fair name and future welfare of the camp require that those who have come into the district and invested their money in good faith, be protected and insured peaceable possession of their property.

Mining Summary.

ARIZONA.

YAVAPAI COUNTY.

The Wildflower group in the Pine Grove district has been sold by F. M. Murphy to the Yavapai-Gold-Silver-Copper Consolidated Co., the purchase price being unstated. The group consists of thirty claims, 13 being held under U. S. patent, the other 17 being held and developed under right of location. The property includes the Old Reliable mine, which has been worked from time to time since 1875, its ores yielding by the arastra process over \$100 per ton. The vein of this mine follows a syenite and porphyry contact, and is developed by several hundred feet of cross-cutting. The other claims of the Wildflower group are opened up by several thousand feet of adits, shafts, and underground workings, exposing large bodies of ore. Besides mineral rights the locations cover water privileges ensuring sufficient power for a reduction plant which will be erected later. Preliminary to starting extensive operations the company will put a force of men to work building a road from the Crown King terminus of the Bradshaw Mtn. R. R. to the camp, a distance of three miles, over which the new machinery will be hauled. Houses are in course of erection for the accommodation of miners and engineers. The company is also the owner of the Tiger group about six miles further west, in the Bradshaw Mtn., and the adjacent California and Boston properties, all being developed by a large force of men with satisfactory results.—The recently organized Verde-Grande Copper Co. has decided to vigorously prosecute work upon its holdings on the south slope of Smelter hill and adjoining the United Verde mine. A wagon-road and the necessary houses will be built at once, and a double-compartment shaft started with a view to going down after the orebody expeditiously.—A little over a mile southerly from the Verde-Grande, the Pittsburgh-Jerome Co. has its shaft down about 400 ft., and the bottom of the shaft is heavily copper-stained material of a slaty character. Pay-ore was encountered at the 255 and 358-ft. levels. At the last named, the shaft entered and passed through 12 ft. of pay sulphide ore.—Two carloads of ore carrying good values in copper and gold are on the dump at the Little Daisy mine, ready for shipment to the Humboldt smelter. This property is situated in the Mineral Point district, which embraces a stretch of country along the foothills of the Black Hill range from the mouth of Yeager cañon to the headwaters of the Verde river at Del Rio. The Little Daisy has its shaft down 90 ft., exposing a five-foot pay-streak at the bottom.

CALIFORNIA.

AMADOR COUNTY.

A rich strike has been made at the Fremont mine, near Amador City, a large vein of high-grade ore having been exposed last week in firing a blast. Guards were placed in charge of the mine to prevent the ore being stolen on its arrival at the surface, free gold occurring in sufficient quantities to make this precaution necessary. It is estimated that over \$50,000 has been taken out of the mine during the past seven days.

INYO COUNTY.

A rush has set in to a new goldfield in the Sierra Nevada mountains, seven miles south of Olancha. The camp is hidden away in a cañon that opens upon the desert 79 miles from Mohave, 19 miles from Keeler, and seven miles from Hawaii Meadows. The nearest railroad is at Keeler, the terminal of the Nevada & California narrow gauge. Entrance to the cañon is by a wagon-trail already worn from Olancha. There is an abundance of water and timber. On a ridge to the south is the Gilt Edge claim, the original discovery made by W. E. Higgins and partners. The ore contains petzite, a telluride consisting of two parts gold, two parts silver, and one part tellurium. From the last-named metal the new camp derives its name in common with the famous Colorado mining centre, 'Telluride.' A 15-ft. shaft on the Gilt Edge cut a vein 16 in. wide, the ore running from \$180 to \$250.

SISKIYOU COUNTY.

An important deal was recently made in western Siskiyou by which Henry E. Wood, of Denver, acting in behalf of Colorado capital, has purchased the interest of A. C. Brokaw in the Advance group of claims in China Gulch, Salmon River district. This is the most important deal in the history of western Siskiyou. It is believed that the new owners will secure the entire China Gulch basin, at a cost of many thousand dollars, and will then arrange to operate the properties on an extensive scale. Development work will be kept going upon the Advance mines constantly, and as soon as machinery can be placed upon the ground in the spring, a large aerial bucket tramway over a mile long will be erected for handling the ore from the mine to the mill. An electric power plant, machine-drills, and other improvements will be installed at the mine, together with additional stamps. The mine has never looked better, the lode averaging over eight feet wide, and the pay-shoot prospecting for over a thousand feet. The property has not yet been developed to a greater depth than 100 ft. A mill test upon 1,500 tons has been run since the mill was erected this summer, the ore averaging \$40 per ton.

TRINITY COUNTY.

W. R. Beall and W. R. Bigelow have secured a bond on the old Indian Creek Co.'s placer and quartz properties in the Indian Creek mining district, near Weaverville. These properties were purchased by Dr. D. B. Fields about a year ago. The placers have been steadily worked with good results, returning last season \$2,200 per acre, at an expense of \$800 per acre. The water right appurtenant to the mine is one of the best in the county. The quartz claims adjoin the placer upon the opposite side of the creek, and are eleven in number. The lode runs east and west, and dips into the mountain at an angle of 35°. It varies from 3½ to 12 ft. wide, with 2% sulphides. There are 1,500 tons of ore on the dump averaging \$6 to \$8 per ton.—The power plant for the Bullychoop mine, near Weaverville, has been finished, and its mill will soon be dropping 30 stamps on ore that has been accumulating during the erection of the mill. The company has one of the best equipped plants in the county. In a lode of low-grade ore going \$4 per ton, a rich streak occurs, four feet wide, and assaying \$60 per ton. With the improvements recently installed, ore can be mined and milled for less than a dollar per ton. The mine will be operated all winter with a force of about 100 men.

TUOLUMNE COUNTY.

(Special Correspondence).—There will soon be great activity in the Nonpareil mine, with A. P. Dron as superintendent and H. M. Stanley as foreman. It is reported that a mill will be erected and a compressor installed.—Operations are to be resumed at the Cosmopolite with a large force of men.—Driving north and south from the cross-cut is going on at the Yorktown mine, on the Klein ranch, near Stent, and ore of the same high grade as that found when the recent strike was first made, is being taken out.—Development work continues on the North Star, near Tuolumne, with good results, and it is expected sufficient good ore will be available within a few more weeks to warrant starting up the mill, which will first be thoroughly repaired.—Tuolumne Dec. 10.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—Rees C. Vidler, president of the Transcontinental Tunnel & Transportation Co., left for London, England, last week for the purpose of financing the purchase of the Waldorf Co.'s mines, near Georgetown, and the Argentine Central railroad, both at present controlled by E. J. Wilcox. The price is said to be \$3,000,000.—S. A. Leebrick, of Idaho Springs, has purchased the British & Victoria group of six claims on Griffith Mtn., for \$5,000 from Rudolph Barth. This property adjoins the Magnet & Sequel group, which are believed to be located on the Lamartine lode.—The Buckeye Co. has secured the Claypool tunnel, on Columbia Mtn., which it will drive 5,000 ft. The adit is now in 750 ft., having cut two lodes from which \$100 ore has been shipped in the past. The enterprise is backed by Denver, New York, and Cincinnati people.—Joe Raymond has encountered ore which assays \$50

per ton in the Paris lode, which was cut by the Raymond adit 500 ft. from the entrance. The Raymond group consists of seven patented claims on Griffith Mtn. The same lode was cut in the Capitol adit at 1,000 ft. below surface, where it showed considerable mineral in a well-defined vein. The Capitol Mining Co. is now shipping carload lots of concentrating ore to be tested preparatory to erecting its own mill.

SAN MIGUEL COUNTY.

The Black Bear mill situated at the head of Ingram falls, three miles from Telluride, has been completed and will start to treat ore from the Cascade group. This plant is one of the most completely equipped in the county, and was constructed for the treatment of Black Bear ore, but it is not likely to be running on that before next spring. A test-run

Relief Map of the Nevada-California Border.

A strike of rich ore has been made in the Cliff mine on Columbia Mtn., in the raise from the lower levels. The property was purchased this year by Dr. Bell, of Minneapolis. The mine has produced large quantities of high-grade ore in the past.—The Golden Glory Co. has acquired the Colorado Tunnel property. The main adit, which is in 500 ft., will be driven ahead, and machinery installed for power drills.

Georgetown, Dec. 7.

of a large quantity of Cascade ore was made by the Black Bear Co. before the transfer, which yielded satisfactory values in gold and silver, gold predominating. The vein is from three to six feet wide, composed of white and brown quartz, the gold being largely free milling.

SUMMIT COUNTY.

(Special Correspondence).—The Country Boy is again shipping high-grade zinc ore, which averages 50%, in carload lots. The company has lately installed an electric

hoist to raise the ore from the 90-ft. winze which is now being deepened below the tunnel level. The pay-streak is about 3 ft. wide and the ore is taken out without blasting, being simply shoveled into cars and sent direct to the smelter. A drift has been run to the west where the winze was started and another rich shoot of zinc ore was encountered. The first shoot has been producing rich ore at the rate of 500 tons per month.—The Blue Flag Gold Mining Co. has remodeled its stamp and concentrating mill on Bald Mtn., above Illinois gulch. The new mill has been started and is turning out a good grade of concentrate. Its ore-bodies are large and of first-class concentrating material, being made up of lead, zinc, and iron sulphides, carrying gold and silver, and the mine is already opened up by a main tunnel and several thousand feet of drifts along the lodes. This property includes the Laurium group and other adjacent property. Robert Niles is superintendent.—The Gold Dust Mines Co., operating the Gold Dust and Puzzle groups, has taken a lease on the old West Side mill in the town of Breckenridge, and is now thoroughly overhauling the mill and renovating it for a steady run on their concentrating ores. For the past two years this company has been shipping high-grade ore direct to the smelter and they have accumulated a large reserve of second-grade ore which needs concentrating locally to make a profit on the ore. By the addition of Hartz jigs and Wilfley tables to the old mill, the plant will be fairly complete and will be able to handle close to 100 tons per day, making good zinc and lead products. James F. Callbreath, secretary of the American Mining Congress, is manager of this property.—The French Creek Co. is making arrangements for the resuming of operations in their large adit in Bald Mtn. This adit is now in over 2,300 ft., and has passed through several veins. It is the intention of the management to do some prospecting by driving along these veins. This project is backed by a syndicate of Colorado Springs capitalists who have other properties in this district.—The management of the Wellington property has just made a contract with a zinc smelter company to handle from 50 to 75 tons per day of high-grade zinc ore; contract to last for a few months until such time as their own concentrating mill is completed and ready for work.—At Montezuma the Fisherman mine has made a new strike of concentrating ore which is being shipped to the Lenawee Tunnel & Reduction Co. The orebody was encountered 800 ft. in from the mouth of the main tunnel and averages four feet in width.—The New Pennsylvania Mines Co. has just completed a big shipment of heavy silver-lead concentrates from their own mill.—The Excelsior mine is being worked again and a new contract has been let for driving the drift from the first level, a distance of 500 ft. This property has of late been closed down on several occasions.

Breckenridge, Dec. 8.

NEVADA.

LINCOLN COUNTY.

(Special Correspondence).—The Quartette Mining Co. is operating on two of their 27 claims in the Searchlight district. The main working shaft is on the Copper King claim, and has reached a depth of 1,000 ft., on an incline varying from 34° near the surface to 70° in the lower levels. The vein varies in width from 10 to 40 ft., and from the 400-ft. level down it is over 30 ft. wide, with the ore increasing, the largest and richest vein being encountered at the lowest level. The mine is equipped with a 20-stamp mill, which has a regular capacity of four tons per stamp. The ore averages between \$40 and \$50 per ton, of which 85% is recovered by amalgamation. The company has been paying dividends of 1% for over three years, and has recently increased to 1½%, with every prospect of an increase to 3% at an early date. Sufficient water for milling and other purposes is obtained from the mine, and a notable feature of this property, as in the Searchlight field generally, is the great depth in which free gold prevails. With the exception of an ore-shoot between the 7th and 8th levels, which carries a large percentage of base ore in the form of sulphide, valued at about \$150 per ton, the whole body of ore so far developed in the Quartette mine is free milling.—Two miles northwesterly from the Quartette, the Search-

light Mining & Milling Co. owns six mineral claims, which were taken over by the company about two years ago from the original locators, O. B. Landon and A. B. Day.

LYON COUNTY.

A new camp has been established on what was reservation ground, 16 miles southeast of Yerington, and named Copper Run. A large number of gold, silver, copper, and lead veins have already been located, and 16 placer claims have been taken up for a townsite. There is a fine spring of water in the vicinity, with plenty of wood and timber adjacent for mining purposes. The town is situated about half a mile west of one of the largest copper lodes in this State, and about four miles south of some old workings on this lode, the vein being traceable for over seven miles. Good prospects have been taken at various points, going anywhere from 10 to 60% copper and \$8 to \$25 gold, and up to 60 oz. silver.

WHITE PINE COUNTY.

Copper ore has been struck in the McDonald-Ely shaft at a depth of 75 ft., and the showing on this vein has stimulated prospecting the north of Robinson cañon, G. L. Rickard having purchased the Christmas group of mines (which adjoins the McDonald-Ely holdings) on the strength of the recent strike. F. Augustus Heinze is said to have acquired interest in this district.—Gold float has been found on the outskirts of Ely assaying \$200 per ton. Much of the ground on which this float was found has already been taken up for copper. A number of prospectors are making an effort to trace the vein.

NEW MEXICO.

DONNA ANA COUNTY.

A rich vein of covellite or indigo copper ore has been recently opened up on the first level of the Lucky mine, near Orogrande. The lode is 10 ft. wide and carries from 20 to 40% copper per ton; it shows 30 ft. down in the winze, and there remains 200 ft. of virgin ground to be opened up.—The Monte Carlo group of gold and copper claims north of Orogrande have been sold to a company recently launched as the Monte Carlo Consolidated Copper Co. The previous owners, Messrs. Culver & Downs, located the group, about ten years ago, after a long search for the original claim located nearly a quarter of a century ago by prospectors who were driven off by Apache Indians, torrential storms afterward obliterating all trace of the shaft. The property now comprises 180 acres of contiguous territory, developed by three shafts each 70 ft. deep, besides trenches and open-cuts. The ore assays from 17 to 35% copper, from 136 to 800 oz. silver, and carries about \$4 gold per ton.

OREGON.

BAKER COUNTY.

The group of claims acquired by the Success Gold Mining Co., in the Cracker Creek district, about one mile south of Hanover, is making a good showing. At surface one vein is from 10 to 20 ft. wide, the assays from which have ranged from \$5 to \$200. W. T. Woodford is in charge.

GRANT COUNTY.

Large shipments of high-grade ore have been made to the Sumpter smelter during the past few weeks from the Buffalo group, about five miles north of Granite. The ore runs from \$80 to \$100 per ton. The mine is being operated by W. T. Kendall and Thos. Daringer, under a sub-lease from W. Elmer, who in turn has a lease from the Buffalo-Monitor Mining Co. In the early history of the mine more than \$1,000 per week was cleaned up by the discoverers, who worked the free-milling ore in an arastra.—Development work on the Ben Harrison group is giving good returns. The main vein has been opened on the surface by cuts and is now known to be continuous for the length of four claims. A shaft was sunk 35 ft. on the hanging wall, and from the bottom a cross-cut was driven to the opposite wall, proving a width of 14 ft. Samples taken gave the following results: \$13.17, \$13.60, \$15.57, and \$7.50, making an average of \$12.36 per ton for the entire width of 14 feet.

Extensive changes and improvements are being made by the Steuben Placer Co., operating the Thornberg placers at North Fork about ten miles from Granite. The present

ditch and flume will be increased from 18 in. to three feet deep, and the pipe-head raised to about 400 ft. instead of 120 ft., by extending the high flume about a mile. For this purpose a contract will be let for cutting 200,000 ft. of logs. The company owns 400 acres of placer land along the banks of the North Fork river. Work is carried on in the pits night and day throughout the summer. Experiments are being made on the black sand, which usually carries off the fine gold and other minerals of value.

LANE COUNTY.

A big ore-crushing house is being built at the Black Butte quicksilver mines. The mill, at the highest point, will be 103 ft. from the ground, and a trestle will run from the 400-ft. adit direct to the top of the building. The management hopes to get the actual production of commercial mercury started and on the market in three months.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Monitor group, consisting of the Ironsides, Treadwell, Monitor, Red Chief, and Red Cloud claims, situated on Missouri Mtn., 12 miles northeast of Republic, has been sold by Z. C. and J. I. Perkins to E. R. Fraser of Spokane, Wash., for \$15,000, of which \$3,000 was paid in cash. An agreement calls for the payment of \$2,000 in 90 days, \$5,000 in nine months, and \$5,000 in 15 months, the purchasers to employ not less than four men continuously during the life of the lease. Quartz and iron croppings are traceable the entire length of the group, from 20 to 100 ft. wide. Considerable surface prospecting has been done, and a month ago a body of ore was struck that assayed \$36 in copper and gold.—The Belcher Mtn. R. R. is in full operation, and has begun grading for two miles for a ground tramway from the No. 2 adit of the Belcher mine to the Oversight group. Two new ore-bins have been built at the Oversight mine, and ore is being shipped continuously from the No. 1 and 2 adits. An incline shaft has been sunk 30 ft. deep, on a small vein of soft oxidized ore, on the Pin Money claim of the Oversight group. The ore contains gold, silver, and copper, while cobalt in the form of smaltite occurs in nodules.—The Bortle Copper-Gold Co. which owns the Gold King, Alpha, and Omega, a group of claims adjoining the Belcher mine on the north, has sunk a 52 ft. shaft near the dividing line of the two properties. A sample from the bottom assayed \$22 per ton in gold, silver, and copper.—R. A. and L. P. Farr have bonded the Manila, South Manila, Cavite, and Manila Fraction claims, lying four miles southwest of Keller, to J. L. Harper and associates for \$40,000, the Farris acting in the interests of the Manila Co. A cash payment of \$5,000 is said to have been made. Mr. Harper took a bond for the purchase of this property over two years ago, and let it expire after making a first payment.

Republic, Dec. 8.

MEXICO.

The Black Mountain Mining Co., of Cerro Prieto, Sonora, Mex., is contemplating the addition of 120 additional stamps, thus doubling the existing plant. The mine is looking well and has large reserves of ore. Noble C. Banks is manager with F. M. Cox as superintendent.

AGUASCALIENTES.

A number of tin discoveries have been made near Aguascalientes. These recent finds are said to run close to 10% pure metal. Lack of facilities for transport and smelting have hitherto handicapped this district. The fact that the properties of Messrs. Pratt and Rettick are reported to have been sold to the Mitchell Mining Co. of New York is believed to open up the prospect of additional smelting facilities for properties in the States of Aguascalientes and Jalisco.

CHIHUAHUA.

A telephone line, 100 miles long, is being built to connect the Dolores mine with the San Isidro station on the Temosachic branch of the Chihuahua & Pacific.—It is stated that about 500 men are at present employed on the Greene Gold-Silver Co. mines in the Sierra Madre country.—The

plant of the Llanos de Oro Mining & Milling Co. has been shut down indefinitely.

The Pacionera mine, in the Santa Eulalia district is shipping about 25 tons of 30 to 50 oz. silver ore daily.—A new strike of high-grade ore is reported in the Buena Tierra mine. It is believed to be a large body.—Copper ore is being shipped from El Tajo mine to the Torreon smelter. This is a new find, and work on this mine, the property of the American Zinc Extraction Co., is being pushed.

GUANAJUATO.

More mills are being built and new companies are being floated. The 120-stamp mill of the Peregrina is near completion; 60 to 80 stamps have been dropping for some time and the remainder will be ready shortly, if not held up by the delay in receiving cyanide machinery. The Guanajuato Reduction and Mines Co. is adding another 80 stamps, making 160 altogether, with the necessary cyanide equipment to correspond. The Amalgamated Mines Co. at La Luz, of which the gambler Al. Adams, of New York, was the leading spirit, will have 100 stamps and cyanide plant ready in about six weeks. The San Prospero Co. will have its 40-stamp mill and cyanide plant ready in sixty days. The Republic Mines Co. was recently organized to take over the Barragana group, which adjoins the Peregrina, and which has a northerly extension of all the veins traversing the Peregrina properties. In addition, the company will own the Cardonas and La Union groups, which contain within their limits about 4,000 ft. of the south end of the Vetra Madre. All these properties have been worked to some extent in the past, but the Mexican owners have held them without doing anything except gophing on the surface. There is a good prospect of a big mine being made. Two electric hoists have been erected and a large force of miners is at work. Fred E. Corning and Capt. Murdoch Wiley, of New York, are among the directors of this new company.

The American and English speaking population of Guanajuato now numbers about 600. For these there have been established recently an Episcopal and Christian Science church, besides the Methodist Missionary church established some time ago. The Masons have a strong lodge and hold a meeting twice per month. Furthermore, the American school has been established and is being conducted under the public school system of the United States. The mining companies have contributed largely to the support of the school. The program of studies and grades approximates that of the American schools. It is proposed by the American colony to erect a schoolhouse, Masonic hall, an amusement hall, and a church on a tract of land in the best part of the city. It is hoped to get a charter from the Mexican Government. A majority of the English-speaking people at Guanajuato consists of college graduates who occupy positions in the managerial or technical departments of the mining companies. The railroad from Marfil is being built and Guanajuato promises to enjoy the best conditions of living. For these reasons it is not surprising that the mining properties in the district are being rapidly absorbed by American capital and it is expected that by the end of next year there will be 1,000 stamps in operation.

The erection of 30 additional stamps was begun by the Guanajuato Reduction & Mines Co., on Nov. 5, and the work is being pushed with vigor.

HIDALGO.

It is stated that John B. Farish has made an offer of 9,000,000 pesos for the Santa Gertrudis, at Pachuca. Carlos de Landero, who represents the owners, is said to hold the property at 15,000,000 pesos. There is a great deal of interest being taken in the established mines of Pachuca.

SONORA.

The sale of two famous gold and silver properties was consummated last week, involving the largest sum of money ever paid for a mine in Northern Mexico. Las Chispas, a famous producer, has been sold to a New York and Paris syndicate for 6,000,000 pesos, approximately \$3,000,000 gold. The Badicanora mines, in the same district, one of the principal claims of the famous Antiguas group, has been sold to Dr. F. O. Pease, of Chicago, and associates. The consideration has not been made public.

Personal.

BEN. B. LAWRENCE is at Denver.

BEN. S. REVETT is in San Francisco.

WILLIAM A. FARISH is at New York.

E. D. McDERMOTT is at present in Spain.

EDGAR RICKARD is expected home this week.

C. W. MERRILL has returned to the Homestake.

W. H. SHOCKLEY has returned to Manhattan from New York.

F. G. MOREHOUSE is visiting Boston from Guanacevi, Mexico.

F. C. ROBERTS is investigating dredging methods at Oroville.

R. GILMAN BROWN sailed from New York for London on December 8.

C. M. FUELLER has been examining mines near Breckenridge, Colorado.

D'ARCY WEATHERBE sails from New York for London on December 17.

A. E. KEABLES, of Denver, is at Silver City, N. M., on mining business.

R. Z. ADAMS, of Georgetown, has gone to Tonopah, Nev., on a mining deal.

M. E. MACDONALD is studying filter-pressing at Virginia City and Deadwood.

J. C. RALSTON is the new president of the California Miners' Association.

G. C. KIRBY is superintendent for the Gold Bar Dredging Co., at Chico, California.

GEO. B. PUTNAM has returned to Denver from City of Mexico and Globe, Arizona.

EDWARD W. SEBBEN is in Wickenburg district, Arizona, making examinations.

F. LYNWOOD GARRISON is examining mines in the Parral district of Chihuahua, Mexico.

RUFUS M. BAGG, JR., is on his way from Chihuahua to West Springfield, Massachusetts.

T. R. MILLER has gone to the Black Hills district in South Dakota on mining business.

W. E. WILSON of Boulder, Colo., is at Goldfield, Nev., looking at some mining properties.

W. E. THORNE is making an examination of copper mines in Shasta county, California.

JAMES W. ABBOTT, of Los Angeles, is examining mines in the Greenwater district, California.

ARTHUR L. WALKER has returned to his home on Staten Island, New York, for the holidays.

JOHN HENDY succeeds the late SAMUEL HENDY as treasurer for the California Miners' Association.

FRED. B. REECE is working in the cyanide mill of El Oro Mining & Railway Co., at El Oro, Mexico.

E. E. ABERCROMBIE is in Utah investigating the condition of the mines in which he is interested.

FOSTER HEWETT is engaged in professional work in San Bernardino county, Cal., and in southern Nevada.

A. C. LAWSON and HAROLD W. FAIRBANKS are experts in the Champion-Home litigation at Nevada City.

CHESTER F. LEE, of Seattle, has gone to Juneau in connection with Alaska-Perseverance matters for London clients.

L. C. GRATON, having finished his geological work in Shasta county, has gone to see the new camp of Greenwater, California.

COURTENAY DEKALB is investigating the old placer mines in San Fracisquito cañon, in Los Angeles county, California.

H. C. CARR, formerly metallurgical engineer with the Joshua Hendy Iron Works, has been appointed superintendent for the Nevada Con. Mining & Milling Co., at Wadsworth, Nevada.

Books Received.

AFTER EARTHQUAKE AND FIRE. This is a handsome volume of 200 pages, illustrated by a number of unusually good halftones and describing the events that drew the attention of the civilized world to San Francisco in April last. The articles are those that appeared in the MINING AND SCIENTIFIC PRESS at that time. Among the authors are G. K. Gilbert and F. L. Ransome of the U. S. Geological Survey, Professors S. B. Christy and A. O. Leuschner of the University of California, F. Omori of the University of Tokio, Philip Argall and J. Parke Channing, W. H. Storms, D'Arcy Weatherbe, and T. A. Rickard. It is a book with a present interest and a future historic value. Price \$1. For sale by the MINING AND SCIENTIFIC PRESS and its agents at Denver, Chicago, and New York.

CLAYS, Their Occurrence, Properties, and Uses, by Heinrich Ries. An octavo of 490 pages, well illustrated. This is a valuable book on a special subject by a specialist of high reputation. It covers the geologic origin of clays, their chemical and physical properties, the varieties, the methods of mining and manufacture, and the distribution of the mineral in the United States. Published by John Wiley & Sons, New York, and for sale by the MINING AND SCIENTIFIC PRESS at \$5.

OUTLINES OF QUALITATIVE CHEMICAL ANALYSIS, by Frank Austin Gooch & Philip Embury Browning. Published by John Wiley & Sons, and for sale by the MINING AND SCIENTIFIC PRESS at \$1.25. This is a small octavo of 145 pages. It gives a brief outline of methods based on many years of college teaching. So far as possible, simple ways of treatment are presented, but certainty of result has been made the main issue.

THE ILLINOIS STATE GEOLOGICAL SURVEY has issued Bulletin No. 3, giving a detailed account of the composition and character of Illinois coals, with chapters on the distribution of the coal beds and tests for calorific value.

Dividends.

On December 4, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. III, of \$360,000. This makes the total paid since January 1, 1906, \$2,340,000, and the total to date, \$7,866,000.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

HYDRAULICKING has been used successfully at Cobalt, Ontario, to strip the surface, exposing the veins underneath the soil and moss. A nozzle with a 3½-inch giant was employed.

THE copper ore of the Ducktown district in Tennessee is essentially a massive pyrrhotite, containing interspersed particles and stringers of chalcopyrite. The ore averages about two per cent.

THE deepest mining in Western Australia is at Kalgoorlie, where the Great Boulder Proprietary mine has recently found pay-ore at 1,900 ft. This mine has paid £2,315,800 in dividends to date.

THE ZINC deposit of the Potosi mine in the Spring Mountain range in southern Nevada consists mainly of the carbonate of zinc in a Carboniferous limestone belonging to the same geological horizon as the 'blue limestone' of Leadville.

A MECHANICAL STOKER that is likely to come into wide use for smelting and other furnaces, is to be installed on certain of the Chicago & Northwestern R. R. locomotives. The machine is capable of hurling coal into the fire-box at the rate of 200 shovelfulls per minute, if necessary.

EXCLUDING the comparatively thin crust, $\frac{1}{30}$ the earth's volume, there are strong indications that the earth consists of a non-radio-active substance with a rigidity approaching that of steel, with an average temperature of about 1,500° C. and a density at that temperature of, say, 5.6.

THORITE is a valuable mineral that may be found in the black sands of the Pacific slope. It occurs as heavy black cubes, resembling altered pyrite. It is usually associated with zircon, monazite, etc. The value chiefly depends on its use for the manufacture of incandescent gas mantles from the oxide of thorium.

At the Granby Consolidated, in British Columbia, the total cost of operations, as given in the recent annual report, was \$3.29 per ton of ore. The net cost of the copper produced was 8.35 cents per pound, after deducting the value of the gold and silver obtained. The output included 19,939,004 lb. copper, 316,947 oz. silver, and 50,020 oz. gold.

BENTONITE is a fine-grained clay, it has a soft unctuous feel and when mixed with water it makes a perfect paste. It is essentially a hydrous silicate of aluminum, akin to kaolin. The chief use for it is for giving body and weight to paper, but it is also employed in antiphlogistine and as an adulterant in candies. The chief deposit is in the Laramie basin, in Wyoming.

BLASTING in rock at high temperatures may be effected by putting a hose in the drill-hole with a running stream of water for some time immediately before blasting. The powder may then be wrapped in sheet asbestos and the fuse fixed in the cartridge and lighted before being inserted in the hole. The hose should then be quickly withdrawn, the cartridge inserted and tamped promptly.

DRILLING in soft rocks, such as slate, that sludge quickly, may be slower than in the toughest trap. The

success of the Leyner drill in friable rocks depends largely on the use of water under pressure. The time taken to drill a hole in such rocks, neglecting that lost in fitchered holes, may be twice that of working in ordinary granite. In sandstone, drill-steel should be used with a blunt square end $\frac{3}{16}$ inches thick.

THERE is no limitation to the number of lode-claims which may be located by an individual provided there is a lode or vein in place actually discovered within the limits of each location. Locations paralleling side-lines of other claims would be invalid unless they were based upon separate discoveries. Extensions of an original location on the end-line of a discovery claim could be made by the same locator provided that he discovers the vein actually to exist in the extended claim.

MURIATIC ACID is a name which dates back to the eighteenth century when chlorine was supposed to be oxide of murium. The elementary nature of chlorine was established by Davy in the first decade of the last century, a discovery which dealt a death blow to the theory that all acids were oxides. That this monument of a theory, based on false hypotheses, and long since buried in oblivion, should be retained, is a mere confession of ignorance on the part of certain would-be chemists.

IN connection with designing sluices to give best results for transporting material combined with most efficient gold saving, it has been practically demonstrated that wide sluices carry more material with less grade than narrow ones and save more gold. The principle of saving gold depends upon having the thinnest film of material traveling along the bottom of the sluice in continuous motion, using a sufficient depth of water only to prevent the fine sand from packing the riffles. The depth of water in all cases must be sufficient to cover the large stones, for example, if the material to be sluiced carried a large number of stones 6 to 8 in. diam., the depth of water should be about seven inches, and on this basis the width and grade of the sluice-box should be figured out. It is impossible to go fully into the merits of the questions of *A* and *B* without first knowing the quantity and sizes of the material to be treated, but on general principles the sluice of *A* will give the best results. The sluice of *B* with about one-half the quantity of water used by *A* will, with similar material, give same results as *A*'s sluice.

THE San Francisco fire taught emphatically that the most vulnerable part of a building, in the case of a big conflagration, is the roof. Several forms of fireproof roofing are now being put forward, and at least two styles are guaranteed to resist flames under all conditions: These two forms are metal shingles and clay tiles. A third, and probably the greatest achievement in tile-roofing from a utilitarian as well as esthetic point of view, is the use of glass. In the first place glass tiles are of the same pattern as clay tiles, and in factory work, upon an open-steel construction, may be inserted just as a clay tile would be in any number or in any position required. This does away with the cost of sheet-metal work, and the absence of this, or even of wire work, is important in many other respects. Galvanized iron and tin yields quickly when it comes in contact with the gases that arise almost invariably from reduction works, factories, and the like. The life of this customary support to the skylight is three years; the glass tile moreover, washes clean, while glass surrounded by sheet-metal work never does. Finally, the light obtained from the use of tile skylights is far superior to that obtained in the old way, the corrugated surfaces of the tile acting prismatically, and perfect dissemination of light follows.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Cyanide Practice With the Moore Filter.

The Editor:

Sir—Mr. R. Gilman Brown's recent contribution to the literature of vacuum filtering, entitled 'Cyanide Practice With the Moore Filter,' appearing in your issues of September 1 and 8, is one of the few articles that have been published on the subject of increasing interest and growing importance to those who have to face difficult problems in cyanidation. Of the few articles so far published, Mr. Brown's is by far the most thoughtful, and contains detail that others have not attempted to give.

As the writer had more or less to do with the construction of the Bodie plant, and its subsequent operation, and since then has had the opportunity of comparing it with the Butters-Cassel installation at the Combination mine, Goldfield, Nevada, the Butters' plant at Virginia City, and the Moore plant at the Liberty Bell mill at Telluride, Colorado, he has gathered a few facts pertinent to the discussion that may be of some interest.

At the Standard, sillex blocks for tube-mill lining were a failure; at the Liberty Bell they are a success. The difference in results can apparently be attributed entirely to the different pebbles used—to the difference in the thickness of the material fed to the tube-mills—and to laying the sillex blocks edgewise instead of flatwise, in the later lining. The other factors affecting the life of the lining can be neglected, in this comparison, as the sillex blocks are of the same grade, and look to be from the same quarry; the speed of the mills is the same, and it would be hard to find two ores more nearly the same (with regard to the percentage of hard quartz and soft slime-forming material) than the Liberty Bell and the Standard Consolidated ores.

At the time the sillex was tried at the Standard, local pebbles of miscellaneous character, and largely of igneous origin were in use. Their consumption was about 50 lb. per ton of sand re-ground. To a large extent they were flat, indicating a sliding rather than a rolling motion. At that time the tube-mill was fed almost entirely from spitzkasten underflow, carrying perhaps 20% to 25% solids. The sillex was 2½ in. thick, and the lining lasted six weeks. At the Liberty Bell, a 2½-in. sillex lining in a mill fed from spitzkasten underflow gave four months of actual service. As all other conditions were practically parallel in the operation of these two mills, except the use of local pebbles in one and flint pebbles in the other, the short life of the sillex at the Standard can, it seems, be blamed entirely on the local pebbles used.

At the Liberty Bell there are three tube-mills, one fed by spitzkasten underflow as already stated, while the others receive the discharge from Dorr scraping classifiers, a coarse product carrying from 45 to 50% solids. In these mills, also, the sillex blocks have been set on edge, forming a lining four inches thick. By setting the blocks edgewise, it seems likely that the wear is increased as the bedding planes of the original limestone seem to be parallel to the flat sides of the blocks. Capping is certainly not so bad with the edgewise blocks. The edgewise lining has already had nine months of actual service, and seems good for several months more. Roughly, the lining in the mill receiving spitzkasten underflow wore at the rate of one inch in two months, as there was some waste, of course, when it was finally removed. In the other mills the rate of wear has been just about half of this or one inch in four months. Here, then, are three mills on the same ore, and operating under nearly identical

conditions, except for the matter of thickness of pulp fed. In the mills receiving the thicker pulp the wear of linings is about half that in the other. The duty of the four-inch lining has been something over 9,000 tons of sand re-ground per inch of wear.

These facts are again illustrated by later results with the tube-mill at the Standard. There, the first wrought-iron lining of ¾-in. plates lasted 90 days and re-ground about 4,800 tons of sand. During its life only a small tonnage of pond-tailing was introduced to the mill. About the time the second lining of the same kind was put in, arrangements had been completed for introducing pond-tailing in addition to the daily mill tonnage, up to the full capacity of the filtering plant. The percentage of solids in the tube-mill feed during the life of the second lining averaged around 45%, as against 20 to 25% before. The life of the second lining was 170 days as against 90; the total tonnage of re-ground sand increased from 4,800 to over 10,000, and the pebble consumption dropped from 6.5 lb. per ton to 2.6 lb. All other conditions were the same. These results speak for themselves. At the Standard, the cost for local pebbles at \$9 per ton laid down at the tube-mill was \$0.225 per ton of re-ground sand, while the cost for flint pebbles under the same conditions at \$70.20 per ton of 2,000 lb. laid down at the tube-mill was only \$0.233 per ton re-ground, and this has since dropped to \$0.091 per ton. Good technical results have been obtained with the Moore plant at the Standard during the last half year. The extraction has been increased and the cost lowered. These results are entirely to the credit of Mr. H. H. Kessler, who had been in charge of the plant since the first of the year.

At the Standard, during the time the tube-mill was shut down waiting for the cement to harden in the sillex lining, the Moore plant limped along as best it could without re-grinding. The sand accumulated wherever it had a chance. The settlers, the agitators, and the filtering vats all furnished their quota of sand and grief. A crew of about six men was kept busy all the time repairing filters, and this one month alone made a decided increase in the costs for the whole year.

Mercury-step bearings for the agitator shafts were a good deal of a failure. The balls ground the iron and the mercury together into a nice iron amalgam, and their use was abandoned.

Mr. Brown has described the basket hoisting arrangement at the Standard. At the Liberty Bell, the baskets are hoisted for transfer by means of hydraulic cranes, operated under a pressure of 250 lb. These work well, and give much less trouble than the differential chain hoists at the Standard. Where high-pressure water is not available, an automatic high-pressure pump installation, such as is used for elevator service, could be utilized. At the Liberty Bell also, an independent electric motor drive is used for traversing the cranes. This is much the best arrangement where one crane serves a number of baskets. The long filter as installed at the Standard did fairly good work, but there was, nevertheless, considerable trouble from twinning or coalescing of the cakes on adjoining filters, which prevented efficient washing. The filters continually broke loose from the spacing bars, and before the writer left Bodie he was seriously considering the advisability of dividing each of the 16-ft. filters into two units and stretching the canvas on iron frames. This was not done, but, from the experience elsewhere with the smaller filters, it would be an improvement. Mr. Brown has called attention to the greater efficiency of the filtration when the pulp is thick. This is a matter that should not be overlooked in the design of filtration plants, as it affects the capacity in a very large degree. The reason seems to be mainly that in the thicker pulps the sand is buoyed up, and a better and

more permeable admixture of sand and slime is obtained in the cakes.

It is satisfactory to record that the estimated capacity of the Standard plant of 3,000 tons per month has been exceeded by 500 tons during the months when uninterrupted excavation could be carried on in the ponds. Mr. Brown's statement that there was no accumulation of weak solution in the plant, applied to the first period of the operations. After all sources of mechanical loss of solution had been eliminated there was a constant accumulation of weak solution, which had to be run to waste. Mr. Brown makes incidental mention of the Butters-Cassel process as being an inversion of the Moore process, and points out the common essential feature of the two, which is, the adhesion to the filter of a cake of slime, thereby making possible its removal from the unfiltered remaining pulp. In the Moore process the filters are transferred from loading to washing vat, etc., and back again, while in the Butters-Cassel process the filters are stationary, and the pulp, wash-water, etc., are transferred to and from the filtering vat. When large capacity can be obtained from a relatively small filtering plant, the Butters-Cassel process has several advantages over the Moore process, but where the filtering plant must be large, the reverse is true.

It must be borne in mind that there is a wide variation in the slimes made from different ores and that they act differently in filter-plants, so that a plant designed to handle a certain tonnage at one mine will have a different capacity at another. Thus, at the Combination mill at Goldfield, the loading period is only 30 minutes, while at the Standard it varies from 2½ to 6 hours, depending on the proportions of clay slime and fine sand in the charge, and the thickness of pulp. Therefore, a plant designed to handle 60 tons per day of Combination slime would fall far short of handling 60 tons of Bodie slime. At the Liberty Bell the loading period is one hour, while at Butters' Virginia City plant, the time varies from 30 minutes to one hour. At all of the plants it is the aim to build up a cake of from ¾ to 1 in. thick.

It will be assumed here that the essential operations of loading, washing the cake, and discharging in water, will require the same length of time with the two processes on the same slime, and this discussion is consequently narrowed to a consideration of the relative merits of transferring the filters and transferring the pulp, wash-water, etc. It is true that with the Butters process a somewhat higher vacuum can be maintained within the filter, on account of the possibility of arranging for bottom solution discharge from the filters, which cannot be done easily with the Moore process. The difference is not great, however, as the solution is raised in the suction pipe in the Moore filters on the principle of the air-lift, and there is not, consequently, a solid column of solution, reducing the vacuum foot for foot of lift in the suction pipe. The rate of loading, also, does not increase directly with the vacuum, but is greater at times with a lower than with a higher vacuum.

At the Liberty Bell, when everything is working smoothly, the Moore plant will just about hold even with the mill crushing 350 tons per day. In order to give the cakes a preliminary weak solution wash and allow also for repairs, another set of filters and another washing vat are to be installed. Besides the necessary settlers and agitators, the plant at present contains six vats, two of which are for loading, and five baskets or filter sets. The baskets are transferred by two overhead traveling hydraulic cranes, and each transfer takes ten minutes. Each complete cycle requires two hours and forty minutes, divided as follows: One hour and ten minutes loading and transferring; one hour and thirty minutes washing, discharging, and transferring back to loading vat. The

time required for a cycle with the Butters-Cassel process depends on the time required for transferring pulp, water, etc., which is dependent on the size of vats and pumps.

To arrive at a comparison, let it be assumed that the Liberty Bell plant is to be changed from the Moore to the Butters system. Instead of the present arrangement of two loading and four washing vats, these, and the additional ones necessary will be used for all operations. At Virginia City the time of filtering and emptying the filtering vats is from 15 to 20 minutes. At the Combination it is from 15 to 25 minutes. Each filtering vat at the Liberty Bell contains 3,050 cu. ft. A 6-in. centrifugal pump at normal speed would fill or discharge a vat in approximately 28 min., a 7-in. pump in 18 min., an 8-in. pump in 14 min., and a 10-in. pump in 7.5 minutes. The large pumps involve the use of large valves, which are a source of trouble in pumping sand, while the smaller pumps involve a larger plant. For a middle course, let us consider the installation of 7-in. pumps. It will practically be necessary to install a pump to each vat, in order to avoid undue valve complications. The cycle for each vat, then, will be as follows: Loading one hour, pumping out pulp 18 min., pumping in water 18 min., washing the cake one hour, discharging 15 min., pumping back water 18 min., pumping in pulp 18 min., total 3 hr. 27 min., say 3 hr. 30 min., as that much, if not more, extra time will easily be consumed. This cycle is longer by 50 min., than with the Moore plant. At 45 filter-charges per day—the usual run—there is a total time increase of 37 hr. 30 min. required to handle the tonnage, and provision will have to be made to handle 11 extra charges per day over what the present plant would take care of. This means the installation of three more filter sets and two more vats. In addition, two storage vats would have to be provided, one for water and one for pulp for taking care of the flux of material during operation. These should have a capacity of at least 6,000 cu. ft. each, and more than this would be desirable. We have, then, two filtering vats of 3,000 cu. ft. capacity, three additional baskets, eight 7-in. centrifugal pumps, with the necessary pipe connections, three-way and single valves, belting, line shafting, motor drive, etc., and a light crane for handling filters for repairing; and two storage vats of not less than 6,000 cu. ft. capacity each, all of which are balanced against two heavy traveling hydraulic cranes, with the necessary heavy track supports. Roughly, the first cost would be about \$6,000 at Telluride in favor of the Moore process. The chief expense, however, amounting to more than the increased first cost, would be the power cost for driving the centrifugal pumps. The power required for pumping would vary from a minimum at the beginning to a maximum at the end of the transferring period, complicated of course by the workings of the various pumps, to the extent of their effect on the height of material in the storage vats. At the Liberty Bell, any arrangement that could be made without the reconstruction of the present filtering vats, would necessitate each pump working against a maximum head of 19 ft., and each pump would then take about 11 h.p. part of the time. As power is bought on peak load in the Telluride district and costs a minimum of \$5 per horse-power month, it would be hard to say what the extra power bill would be. Should four pumps be working near the maximum lift at one time, which would not be unlikely, the bill for the month would be about \$225. It would probably not be less than \$150 any one month, and might run up to \$300 or \$400. There would be no saving in labor in one plant over the other, as one man on a shift would be required to attend to the filtering in either case.

EDWARD H. NUTTER.

Telluride, November 25.

The History of Mining at Guanajuato.

Written for the MINING AND SCIENTIFIC PRESS
by T. A. RICKARD.

It is uncomfortable to arrive at one's destination just before dawn, but the discomfort is not without compensation. Owing to the wretched train service between Mexico City and Guanajuato (406 km. or 252 miles), one arrives at Silao at 1 A. M. and then, changing to a branch railroad 14 miles long, one arrives at Marfil at 3 A. M., whence a horse-car bears the traveler to Guanajuato, a distance of four miles and occupying an hour. The car is pulled by mules, at a sharp trot, along a winding tramroad that follows the bottom of a ravine; there are glimpses of high walls, dark archways, and silent courtyards, an occasional hooded figure comes within the rays of the

which extended an array of steel tanks indicative of a cyanide plant; to the right were the white-washed houses occupied by offices and to the left rose a loftier building—audibly, a stamp-mill. The whole foreground was surrounded by a wall on which the sunlight played gladly. Beyond were low roofs and trees, rising on hill-slopes, partly under cultivation and leading to a brown ridge whose clear-cut edge was silhouetted against the blue of a perfect sky. It was the Hacienda San Francisco de Pastita, an old Mexican reduction works, now transformed to modern methods, it was an island of Anglo-Celtic energy in the midst of an old Spanish mining centre, and the spirit of the men and the machinery of this new mill of the Sirena mine was to the old era represented by the decrepit town outside its walls as the invigorating sunshine of this bright morning to the dark

Guanajuato. One of the Great Mining Cities of Mexico.

feeble lamp at the front of the car, other lights are infrequent; soon the tram penetrates a thickly built town, the mules awaken echoes as they scramble over the cobbles; the reverberations are lost in narrow alleys, but there is no sign of life, save the occasional watchman who blows his whistle to prove himself awake and to prevent the other watchmen from falling asleep—incidentally telling any prowler just where to avoid him. Up a steep gradient, almost brushing the walls that look down on either side, around sharp turns that threaten a capsize, over a narrow bridge and along a stream flanked by rustling trees, and then the journey is over. A friend conducts me to a lofty wall, a door opens, we are in a moonlit *patio*, in front of a white colonnade, in that light as poetic as the moonlight itself, the effect of which is heightened by a sound as of surf borne inland from the shore; it seemed the voice of the distant sea, but it was the muffled roar of a stamp-mill. However, that rhythmic swell served to put me to sleep, deeply grateful for a little rest after the tiresome travel of the night. This was part of the compensation, but the best of it came on awakening three hours later.

It was a sunny morning, with all the coolness of the highlands and all the fragrance of the tropics; going on the portico, I found myself overlooking a lawn behind

weariness of my experience during the night that was past.

Guanajuato, in the State of the same name, is a city of 50,000 people, situated at an altitude of 6,600 ft. among the foothills of the Sierra de Santa Rosa. The air is dry and clear, colors are vivid, lines are defined, and the sunlight is brilliant. The town is not without character, for it is adorned by many churches and other impressive buildings; it lies ensconced among terraced gardens and brown hills, on the higher slopes of which stand the battlemented enclosures and picturesque churches of historic mines. Their story is worth the telling.*

The history of Guanajuato begins in 1526, six years after the Spanish Conquest, when the mineral wealth of Mexico was being eagerly sought out by the hardy *conquistadores*. To the north, the mines of Zacatecas and San Luis Potosi had been uncovered; the road to them, from Mexico City, passed near the site of Guanajuato, but in those days it was dangerous to depart from the highway, for the natives, the Chicmecas, were unfriendly. A fort was built at Santa Ana, and this became the first European settlement in the region. Prospecting became more practicable, but no mineral

*And in the telling of it, I am indebted for many of my data to Capt. W. Murdoch Wiley, who has studied the records.

discovery of importance followed, until 1548, when the silver mine of San Bernabé was discovered at La Luz, six miles from the Guanajuato of today. Two years later rich ore was found on the hills adjacent to the present city, the Rayas mine being started by a Spaniard of that name. The document that registered this fact is the oldest in the archives of the Court of Mines at Guanajuato. It was not until nine years later that the work done at the Rayas and Mellado mines led to the recognition of the mother vein, *la veta madre*. The ore was mined for a width of 100 ft., so wide indeed as to postpone further exploration along the course of the lode. But the ore found by the Mellado shaft, in 1559, suggested the idea of continuity and caused an extension of activity, so that it was not long before mining operations were under way from the Tepeyac to the Sirena workings. To those of us who regard the discovery of the

Indians and the other forbade the branding of a slave in the face.

Within a century, that is, by 1700, the population quadrupled and the camp doubled its area. Immigration was slow, for Spain was a long way off in those days of uncertain sea voyages; the transport of supplies was both laborious and hazardous, the whole European population of Mexico was still meagre, and mining methods were as yet primitive. But the discovery of gunpowder and its application to mining, the introduction of pumps and the accumulation of wealth among the mine owners, all tended to enlarge the scale of operations until Guanajuato, toward the end of the 18th century, became one of the great mining centres of the New World.

The big mine owners won such wealth that, like their modern successors in Nevada and Montana, they became legislators and were given seats in high places; they

Near La Presa. The Modern Quarter. La Bufa in the Background.

Comstock, less than 50 years ago, or even the event at Sutter's Mill, 58 years ago, as a historic event, it is worth noting that the happenings briefly chronicled in the foregoing lines occurred before 1600 — before the first settlement of Virginia, shortly after the sailor captains of Elizabeth had swept the Spaniards off the seas, and just about the period when Shakespeare and Bacon were busy preparing documents of controverted authorship.

By this time the population of the town had grown to 4,000, and it continued to increase as villages sprang up around the individual mines. In 1619 the town was granted a patent, becoming dignified by the name of Villa Real del Guanajuato. This was a year before the landing of the Pilgrim Fathers at Plymouth.

The industry grew; amalgamation was introduced from Pachuca, the first *patio* being started at the Hacienda de Duran, just below the Rayas mine. The best selected ore was smelted on the spot and, considering the high grade of it, the slag was surprisingly clean, for the remains of old smelter dumps below the Rayas and Cata have been found to assay only two ounces of silver per ton. Forced labor, of course, was employed, and two proclamations bear testimony to the brutality of it, for one of them prohibited the indiscriminate sale of

were granted titles of nobility and enlivened the ranks of Spanish aristocracy. José de Sardañeta was created Marquis of Rayas; Francisco Mathias, the owner of the Cata and Secho mines, became Marquis of San Clemente and Viscount of Duarte, while Antonio Obregon, the discoverer of the Valenciana, became Count of that name. It was a great day for these mine operators. They were consulted in affairs of State, just as nowadays men who contribute to campaign funds are likely to possess what Mr. Mike O'Flaherty termed 'infloo-ence'; they posed as Providence to the poor people, for when times were hard and the corn crop was a failure, they provided work for the needy and saved them from starvation. It is said that the big galleries and comfortable cross-cuts, large enough for the passage of a broad-gauge locomotive, that surprise the mining engineer when he first visits Guanajuato, are the evidence of work carried out with such charitable intent.

When an unusual bonanza was struck, the fortunate miner built a shrine or even a church, in token of gratitude to his tutelary saint. Thus one Sardañeta advanced an adit so as to cut the Santa Anita ore-shoot on its dip, but failing to reach this point before he died, he told his son to continue the good work. He did, and found the

bonanza of Santa Rosa, which made the Rayas mine famous. This Sardañeta became Marquis of Rayas and erected the monumental buildings whose flying buttresses and sculptured portal, surmounted by the figure of the archangel Michael, are today the glory of the San Miguel shaft-house.

The church of Valenciana is another such memorial of successful prospecting. This edifice was consecrated in 1778; though badly cracked in many places and doomed to destruction, its fine harmonious facade in carved *cantata* was rendered doubly impressive when I saw it at the end of a day's investigation of the old mines, and, full of reminders of a most romantic chapter of mining history, watched the shafts of sunlight suffuse the old church front with a glory richer than that of the treasure vault of silver that it commemorated. The church was built by Antonio Obregon, a Spanish miner, who discovered a great orebody north of the Cata mine, in ground that had long been held to be barren; he had thought otherwise and prospected for three years until penniless. Then a merchant of Guanajuato provided some funds, until he too was bankrupt. Others were persuaded to share in the venture, only to lose their money, until Obregon won the name of *el tonto* (the fool) *de Valenciana*. But his justification came at the end of seven years of persevering work, when he broke into the biggest bonanza ever found on the Veta Madre. It was much more than his fondest expectation, for, while the Tepeyac had been worked in a desultory way from 1590 and the outcrop of that vein in the Valenciana ground has yielded some ore, it is doubtful whether any such ordinary body of mineral would have repaid the long and expensive search made by Obregon and his backers. In a few months all the expenses of years were repaid and eventually Obregon became, the chronicle says, the richest man in the world, at that time. The immediate origin of the church is told thus: On the ground near the mine, Obregon marked out an irregular quadrangle within which the miners were told to place the handful of rich ore which each man was allowed, for this exceptional purpose, to bring out of the mine. It was a custom that recognized the innate tendency of the miner to purloin a little—a specimen or a sample—of the rich ore that he was helping to extract; and by requiring his men to donate that larcenous portion of mineral for the benefit of Holy Church, Obregon was finally able to do a great deed without unduly taxing his own receipts. The quadrangular area referred to was eventually covered three feet thick with rich ore; this was sold and the proceeds of it were employed to build the church. It was begun in 1765 and finished in 1785; it is said to have cost \$1,000,000, which was about equivalent to the annual income of Obregon. He made gifts to the Crown and, becoming the wealthiest subject of Spain, he was made Count of Valenciana. This was at the time of the American revolution and since then we have had many a Monte Cristo among mining adventurers, a motley crew of ill-balanced men, from vulgar spendthrifts like Tabor and Barnato to great-minded builders of empire like Cecil Rhodes and Alfred Beit.

At the end of the 18th century the mines of Guanajuato were the foremost of their kind. It was then that the Valenciana shaft was sunk to 1,800 ft., and it is still the deepest in the district. This work, done by Obregon, was completed in 1785 at a fabulous expense. It is said to have cost a million, though even this expenditure becomes small relatively to that of the Combination shaft, sunk on the Comstock lode, in 1881; this was 3,100 ft. deep and cost \$6,000,000. However, the cost of the big shaft of the Valenciana was offset by an extraordinary production, stated at \$300,000,000, most of it extracted during the last half of the 18th century. This

figure corresponds with the total output of the Comstock up to the time when the lower workings were abandoned, in 1884. On August 20, 1804, the King's tax, amounting to the sum of \$2,648,866 was paid. As this represented one-fifth of the yield of a period of five years, it serves to substantiate even the extraordinary statistics of these old mines. The other mines on the Veta Madre and those on La Luz veins also produced enormously at this period, so that the population of the district at the beginning of the 19th century had increased to 100,000. This was the time of Humboldt's visit. He says that "the whole vein (the Veta Madre) of Guanajuato may be estimated at four ounces of silver per *quintal* of minerals." As a *quintal* is 100 lb., this means ore averaging 80 oz. per ton of 2,000 pounds.

Then came the long years of the revolution against Spanish domination. In 1810, when at the height of her prosperity as a mining centre, Guanajuato was attacked by the Republican forces under Miguel Hidalgo, a priest, who became the hero of the Mexican war of independence. There was desperate fighting and the city was captured. The entire fabric of government and of business went to pieces. The warring factions made forced loans on the mines, horses and provisions were wantonly seized, life became insecure, so that mining operations were discouraged and all work of importance was discontinued. Deep work ceased entirely, no shafts were sunk, and the production of ore was reduced to infrequent shipments taken from supporting pillars and from the sides of old stopes. Even such decadent mining became insignificant as the miners were driven toward the surface by the slowly rising water. It was at this period of general lawlessness that the heavy walls with watch-towers were built around the mines, until every property of consequence had the look of a fortress. Similar protection was given to the reduction works, which became fortified enclosures, for the *patios* were frequently robbed of their clean-up by roving bands belonging to both factions, who made the necessities of their organization an excuse for a general system of pillage and murder. The battlemented ruins that survive in the vicinity of Guanajuato, are eloquent of this period of lawlessness and afford today a picturesque setting to mines already romantic through their earlier traditions.

Twelve years elapsed before the Spanish rule ended in the crowning of Iturbide as the first Mexican Emperor, at Mexico City, on July 21, 1822. During the interval the population of Guanajuato dwindled to 20,000 and mining almost ceased. With the restoration of order, the mine-owners set to work to rehabilitate their properties. Among the most enterprising was Don Lucas Alaman, who represented the new Republic at London and was an enthusiastic believer in the mineral wealth of Guanajuato. He interested English capitalists in his schemes, with the result that two large companies were formed, the United Mexican Mining Association and the Anglo-Mexican Mining Company. They acquired several of the biggest mines on the Veta Madre, besides others of the Sierra and La Luz systems. The old workings were unwatered and the mills were renovated. But it was not smooth sailing for these English companies, there were periodical local insurrections, life and property were still insecure, and mining was attended by many interruptions. In 1832, one Ariste, at the head of a 'regenerating army,' or *ejercito regeneradoro*, swooped down on the Rayas mine, then the property of the United Mexican Co., and lifted silver and corn to the amount of \$26,000.

THE scientific distinction between solid and fluid may be derived from the common idea of a solid as that which has a form of its own, while the fluid takes the form of the containing vessel, bounded by a level surface on top.

Recent Improvements in the Cyanide Process.

By F. L. BOSQUI.

*It was nearly twenty years ago that two Glasgow chemists, MacArthur and Forrest, made the first practical application of the dissolving action of a dilute cyanide solution on gold. The process was at once adopted in New Zealand and South Africa. In the latter country all the conditions were most favorable to its success; and the enormous profits yielded by the pioneer plants at once established cyanidation as a process of the greatest commercial importance.

The procedure adopted in the Transvaal was simple in comparison with recent modifications of the process. The tailing from the stamps, after hydraulic concentration of coarse sand and sulphides, was gathered in leaching vats; the slime that overflowed was run into huge shallow vats, the surplus water decanted, and the slime subjected to a series of agitations and decantations, until the mineral that it was found economical to extract was finally precipitated from the solution.

At first, zinc shaving was universally used as a precipitant, but this was superseded by the electrolytic deposition of the gold on sheets of lead. This was adopted in all the representative plants; but its popularity soon waned, owing to the production of troublesome by-products, the awkwardness of the clean-up and bullion recovery, and the unsatisfactory deposition as compared with that obtained on zinc. Its chief advantage was that it recovered the values from extremely dilute solutions, but this advantage was nullified by Betty's discovery that zinc shaving, if dipped in a weak solution of lead acetate, would accomplish the same thing.

During recent years, no radical changes were made in the process in South Africa. This was due to the serious blow given the mining industry by the Boer war; and also, in part, to the conservatism of metallurgists on the Rand and their reluctance to adopt important innovations originating elsewhere. The brothers Denny were the first of the Rand metallurgists to recognize the importance of finer grinding, and their energetic advocacy of tube-milling and filter-pressing finally resulted in the acceptance of Australian methods.

It was during the lethargy of cyanidation on the Rand that the filter-press and the tube-mill were introduced in Western Australia. In this connection the interesting fact may be noted that all the important devices introduced into cyanide practice had been previously used in other industries. Even the pipe distributor used for distributing tailing in a leaching vat was an adaptation of the common lawn-sprinkler. The filter-press had been employed to strain solutions in the refining of sugar; the tube-mill had been in use as a dry-grinding machine in the cement industry.

The metallurgists of Australia never took kindly to decantation in slime treatment, and the introduction of the filter-press was the result. In justice to African operators, however, it must be said that decantation was well suited to existing conditions. The product they were handling was too low-grade to stand the prohibitive cost of filter-pressing. In Western Australia, the filter-press was applied to a much richer product, and one much better adapted to the method.

The obvious objection to the old type of filter-presses is the high cost of installation and operation, but they nevertheless enjoyed a great success; and it is worthy of note, in observing the evolution of the process, that they were a means of emphasizing the importance of fine grinding and helped to establish the tube-mill. It has

always been a truism in cyanidation that the finer the product, the higher the extraction. This is the case with but few exceptions. To apply this principle required two things; an economical machine for fine grinding and a filtering system that would be at once efficient and economical. You are all no doubt familiar with the tube-mill as now applied in cyanide work. It consists of a sheet-steel cylinder with cast-iron ends, varying in size (the largest mills are 5 ft. diam. by 22 ft. long), and supported either upon trunnions or upon steel tires revolving on rollers like a chlorination barrel. The interior of the mill may be lined either with cast iron, or a species of natural flint known as 'silex.' The latter is the more commonly used, and is sold in two sizes; blocks 2½ in. and 4 in. thick. The silex lining is laid in cement and will last from four to eight months, depending upon the ore. When ready to operate, the mill is changed about half-full with flint pebbles. The product to be reduced is fed into the mill either through a spiral, or a device of the stuffing-box type, and the re-ground material is discharged at the opposite end, being finely comminuted by attrition against the flint pebbles and the lining during the slow revolution of the cylinder. The average speed of the tube-mill is from 25 to 35 revolutions per minute. The fineness to which the sand is reduced will depend upon several factors, chief among which is the amount of water used. The best proportion has been found to be one part solid to one part water. As a machine for economically reducing ore to an extreme fineness, the tube-mill has no equal. The cost of operation is variable. In this country and in Mexico it will range between 20c. and 40c. per ton. The work at El Oro, Mexico, and at Telluride, Colorado, is representative of the best practice on this continent; while that at the Combination mine, Goldfield, Nevada, probably represents the maximum of cost, owing to high price of power and labor. A small 4 by 12 ft. trunnion mill is installed at the Combination for sliming the 40-mesh product from a Bryan mill. The product of ten stamps, about 35 tons of ore per day, passes to the tube-mill classifier; and of this product about 75% goes to the tube-mill, or 24.6 tons per day. The following figures may be of interest:

Cost of 2½-in. silex lining laid in mill	\$323.50
Life of lining	4 months
Cost of lining per ton of ore stamped	7.7 cents
Cost of pebbles delivered at Goldfield	\$71 per ton
Consumption of pebbles	2.03 lb. per ton of ore stamped
Cost of pebbles per ton of ore stamped	7.1 cents
Power consumed	25 h.p. at \$11.25 per h.p. per month
Cost of power	26.7 cents per ton of ore stamped
Summary, cost per ton of ore stamped:	
Pebbles	\$0.071
Lining	0.077
Power	0.267
	\$0.415

Tending the mill is one of the several duties falling upon one man, and the consumption of lubricants is almost negligible; therefore I have not included these two items in the cost. This cost of 41c. per ton may be assumed to be the maximum for tube-milling, owing to the very high cost of labor and transport in southern Nevada camps.

I have already referred to filter-pressing as an established practice in Western Australia. The press was never very popular in America, and few successful installations are recorded. The most noteworthy, perhaps, is that of the Gold Road mine, near Kingman, in Arizona, where two five-ton Dehne presses have been successfully operated for some time. About three years ago Mr. George Moore, after a series of failures in an attempt to filter-press slime at the mill of the Consolidated Mercur Co., in Utah, devised a vacuum-filter and installed a plant in the Mercur mill. This was the origin of the

*Revised by the author from a paper read before the American Mining Congress.

vacuum-filter, recent modifications of which are to be found at a number of mills in this country. Experiments recently made in Australia so far demonstrate the superiority of this method over all others, that it seems safe to predict the early disappearance of the filter-press.

The unit of the Moore filter is a rectangular wooden frame covered with canvas, and provided with a vacuum drain-pipe extending to the lowest point of the interior. These frames are grouped together in clusters or baskets, which are raised and lowered by means of a hydraulic crane. When lowered into a suitable compartment containing the slime pulp, the vacuum is applied to a common pipe connected with each frame. The solution is drawn through the canvas, and a slime cake varying from $\frac{5}{8}$ to $\frac{7}{8}$ in. thick is deposited on each side of the filter-leaf. The cluster of filter-leaves carrying the charge of slime, weighing several tons, is then lifted from the pulp, shifted automatically to an adjoining compartment containing the wash, where it is again lowered, the vacuum applied, and the displacing operation repeated. The load is again raised and shifted to a bin where the cakes are discharged by introducing air into the interior of the leaves.

The objections to the Moore filter are the high first cost of the mechanism required to shift the slime and the high cost of maintenance. The unmechanical and cumbersome features of this system led to the introduction by Cassel of a stationary filter, and the elimination of the awkward mechanism of the Moore scheme. It remained for Butters to adopt the Cassel principle, simplify it, and so modify it as to make it a pronounced success at his Virginia City plant. In the Butters filter, the leaves are set in a rectangular box or vat, the bottom of the box consisting of a series of pointed pockets, to facilitate the discharge of the spent cakes. The frames are approximately 5 by 10 ft. and consist of a piece of cocoa matting with a sheet of canvas quilted on each side, the whole being stitched on a frame of $\frac{1}{2}$ -in. pipe and securely sewed to this pipe-frame, which in turn is supported on a timber header. The bottom arm of the frame is perforated with small holes, through which the solution enters the pipe when the vacuum is applied. On one side the pipe frame is projected through the wooden header, and is connected with a common vacuum-pipe leading to the vacuum-pump. The frames stand parallel in the filter-box at about 4 $\frac{1}{4}$ -in. centres. The pulp is drawn from the slime-reservoir and pumped into the bottom of the filter-box until all the frames are immersed. The vacuum is then applied until a cake of suitable thickness is deposited, and the excess of pulp is then withdrawn into the slime-reservoir. This operation is repeated for the wash, and the cake finally discharged into the bottom of the box by introducing water under a low head into the interior of the leaves. The accumulated cakes from each charge are removed by sluicing.

This system possesses the great advantage of simplicity and low cost of maintenance. A plant of any size can be operated by one man, who stands on a platform on a level with the top of the filter-box and manipulates the pumps with levers, and the valves with a simple drum-and-sheave mechanism. The 200-ton plant of this type in the Butters mill at Virginia City is operated at a cost of about 10c. per ton of slime.

At the Combination mill 40 tons of this slime per day are being filtered at a cost of about 45c. per ton, as follows:

Three men at \$4; \$12 per day.....	30 cents per ton
Twelve h.p. at \$11.25 per h.p. per month.....	11 " "
Lubricants and incidentals.....	4 " "
	45 cents per ton

This plant, however, has a capacity of 56 tons per day. If worked to its limit of capacity, the cost would be reduced to 31c. per ton. The cost of filter-pressing at the

same plant in the early days of operation was approximately \$1 per ton.

The 15 h.p. consumed is used for the following purposes:

Driving a 4-in. Butters centrifugal pump.

Operating a 12 by 10 Gould's vacuum pump.

Operating a 2-in. centrifugal pump for raising the filtered solution to a clarifying filter-press.

Operating a 2-in. centrifugal pump for returning the slime-overflow from the leaching-vats to the slime-settlers.

Operating stirring mechanism in two slime-reservoirs, 14 ft. diameter.

The power may be distributed as follows:

For actual operation of filter, capacity 56 tons per day.....	9 h.p.
For agitating slime-pump.....	3 "
For uses not connected with filter.....	3 "

The cycle of operation in the Butters filter consumes about 3 hr. 20 min.; it will vary, of course, with the nature of the slime to be filtered.

This type of filter has been installed or is in process of installation at six mills, in Nevada, Mexico, and Salvador.

There are certain conditions, however, where the product to be handled is too low-grade to admit even of vacuum-filtering; these require special study and a special process. The need of a special process to suit a unique condition was never better exemplified than in the case of the Homestake ore.

I shall not venture to describe the different problems encountered and successfully solved by Mr. C. W. Merrill at the Homestake in the cyaniding of a tailing averaging less than \$1.50 per ton. The next and most serious problem to engage his attention was the treatment of the slime, of which 1,600 tons per day of an average value of 80c. per ton have been run to waste from the Homestake mills. Mr. Merrill has devised a filter-press, the unique feature of which is that it can be automatically discharged by sluicing without being opened, thus doing away with the chief objections of the old type of press, namely, the cost of operating. This press is of a common flush-plate and distance-frame pattern, but consists of much larger units. The dimensions are as follows:

Number of frames.....	92
Size of frame.....	4 by 6 ft.
Length of press.....	45 ft.
Capacity of press.....	26 tons
Weight of press.....	65 tons
Thickness of cake.....	4 in.

The pulp is admitted to this press through a continuous channel at the centre of the top of the frames. When the cake is formed, cyanide solution is forced into the cake through channels at the upper corners. At the bottom of the frames, there extends a continuous channel within which lies a sluicing pipe, provided with nozzles that project into each compartment. This pipe can be revolved through an arc of any magnitude so as to play a stream into any part of the cake, washing it down into the annular space between the central channel and the solution pipe. When the press is being filled and leached, the discharge ends of this pipe are sealed. The method of operation is as follows:

The slime, after partial de-watering, consists of about three parts of water to one of solid. In this form it is charged by gravity to the presses at about 30-lb. pressure. The leaching with cyanide solution is done in the press, the effluent solutions being conducted to four precipitating vats where the gold is recovered on zinc dust. There is no power-cost for agitating or elevating, except for elevating the solution to the press. There will be only 0.6 ton of solution handled per ton of slime, of which only 0.3 ton will be precipitated. All filtering will be done by gravity at a cost of two cents per ton.

This plant is being erected on the basis of tests made

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

The Supreme Court of Michigan decided that the mine owner was not liable to a miner for an injury which occurred by a miner being struck by a car coming out of a gallery and down to the shaft by force of gravity, having been permitted to do so by an act of an intermeddler or miner in the gallery; and where it was proved that no car had ever so come out before.

Sommers v. Standard Min. Co., 109 N. W. 30.

The Revised Statutes of the United States provide that where a vein or lode is known to exist within the boundaries of a placer claim, an application for a patent for such placer claim that does not include an application for the vein or lode claim, shall be construed as a conclusive declaration that the claimant of the placer claim has no right of possession of the vein or lode claim, but where the existence of the vein or lode is not known, a patent for the placer claim shall convey all the minerals within its boundaries. Under this statute the Supreme Court of California in a recent case said: "The decisions of the Supreme Court of the United States and of other Courts of high authority, both State and Federal, have settled the construction of this provision of the Revised Statutes, and of these reservations in placer patents as applied to a great variety of cases, and especially as they apply to this case. A vein known to exist within the boundaries of a placer claim at the date of the application for patent, and not included in the application, may be located by an adverse claimant after the issuance of the patent, and a vein is known to exist within the meaning of the statute (1) when it is known to the placer claimant; (2) when its existence is generally known; (3) when any examination of the ground sufficient to enable the placer claimant to make oath that it is subject to location, as such would necessarily disclose the existence of the vein.

And in the same case the Court further said in commenting on the value of a quartz vein, and the sufficiency of proof to establish the alleged claim: "A quartz vein which contains so small a percentage of gold, silver, etc., as to be of no value for mining purposes is not a known vein within the meaning of the law, and whether it is of any practical value is always a question for the jury. In this case there was not only failure on the part of the plaintiff to prove that any of the veins claimed by him could ever be expected to pay the cost of extraction of the ore, but there was, on the contrary, a preponderance of evidence that, at the date of the application for the placer patents, they were generally regarded as valueless, and have since proved to be so. Upon this ground, therefore, if upon no other, the finding against the plaintiff's claim of ownership is clearly supported by the evidence.

Mutchmor v. McCarthy, 87 Pac. 85.

The rule has been established by the Courts that so long as a prior location of a mining claim is subsisting, no rights in any of the ground covered by such claim can be acquired by a junior locator.

Porter v. Tonopah North Star Tunnel & Co., 133 Fed. 756.

Where a person sought to establish title to lode claims which were mostly re-locations of abandoned claims, and he failed to show actual possession prior to the commencement of the action, the doing of the requisite assessment work, or that there existed within the reasonable boundaries of any of the claims a vein or deposit of ore sufficiently valuable to pay the cost of extraction or the cost of reduction, the Court decided that the claims were invalid. It is the rule that a quartz vein which contains so small a proportion of gold, silver, or other valuable mineral as to be of no value for mining purposes, is not a new vein within the meaning of the United States statutes providing for the disposition of mining claims.

Mutchmor v. McCarthy, 87 Pac. 85.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The rock from O. B. A. of Beowawe, Nev., is Rhyolite.

The three specimens from Cordova, Alaska, marked O. M., are metamorphic rocks containing garnet.

The two specimens from Nevada City marked J. H. R. are: No. 1, Epidote, a lime-alumina-silicate; No. 2, Gneiss.

M. E. P. of Alamo, Baja California, Mex., sends the following: No. 1, Magnetite; No. 2, Magnetite and Feldspar; No. 3, Quartz with Chlorite; No. 4, Hornblende Schist; No. 5, Quartz and Orthoclase Feldspar, a quartz-porphyry; No. 6, Quartzite; No. 7, Pegmatite.

Samples from Iron Springs, Ida., marked T. D., are: No. 1, Quartz; No. 2, Quartz, containing much pyrite which has become wholly oxidized to limonite; No. 3, Quartz, containing chalcopyrite and pyrite; No. 4, Quartz, with plates of ilmenite, an oxide of iron and titanium.

SIEDENTOPF & ZSIGMONDY, investigating the Tyndall experiments on the polarization of light in hydrosols or colloidal solutions, have demonstrated that the dispersion of light is due to the presence of the same particles which influence, and to which are ascribed, the other remarkable properties of the liquids containing them. In the Tyndall experiment a beam of light is sent through the space under observation, the observer looks at the space in a direction perpendicular to the course of the beam. If dust or other fine particles are present in that space, they polarize, disperse, and reflect the light, and the beam is seen. If such particles are absent the beam is invisible and the space is said to be optically empty. Siedentopf & Zsigmondy constructed apparatus to send a beam of great intensity into the medium under investigation, and observed through powerful microscopes. Under such conditions particles of metallic gold in a colloidal gold solution appeared as brilliant sources of light, but their shape could not be determined. The investigators connected the number of these bright spots in a space of known dimensions, and knowing the weight of gold per unit volume of solution, made the following assumptions: That all the gold was visible; that it had the same specific gravity when in the colloidal state when massive; and that the particles were cubes. From these values they calculated the linear dimensions of the individual particles. The smallest particles which they were able to count appeared to have a linear dimension of six millimicrons. The exact dimensions of the individual particles on account of the numerous assumptions may only be approximately correct, nevertheless the feat of counting such small particles is little less than marvelous, inasmuch as the smallest particle visible with the best microscope has a linear dimension of 250 millimicrons.

The new region which these experimenters have brought within the range of direct observation is pregnant with the possibilities of future discoveries, the molecules may ultimately come within the range of the apparatus. Lobry de Bruyn for example estimated the hypothetical diameter of the soluble starch molecule at about five millimicrons, while O. E. Meyer estimated the hydrogen molecule at about $\frac{1}{10}$ millimicron.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

ORE CONCENTRATION.—No. 835,120.—Henry L. Sulman, Hugh F. Kirkpatrick-Picard, and John Ballot, London, England.

The herein-described process of concentrating ores which consists in mixing the powdered ore with water, adding a small proportion of an oily liquid having a preferential affinity for metalliferous matter (amounting to a fraction of one per cent on the ore), agitating the mixture until the oil-coated mineral matter forms into a froth, and separating the froth from the remainder by flotation.

PULVERIZING-MILL.—No. 835,104; John H. Elspass, Los Angeles, California.

The combination in a pulverizing-mill, of an outer and inner series of posts, an annular revoluble mortar located between said series of posts, rollers supporting the same, means for rotating the mortar, and annular mortar-centering rings carried respectively by the mortar and the inner series of posts, said rings having opposing edges in the surface of a right cone concentric with the mortar-axis.

HOIST.—No. 834,901; Charles E. Glessner, Ouray, Colorado.

In a hoist, the combination of a substantially constant-speed motor, a driving or power shaft continuously driven in one direction from said motor at substantially constant

speed, a variable-speed transmission gear for connecting the load to the source of power, comprising a spur-gear and an internally-toothed gear, one of which is connected to the power-shaft and the other being adapted to be connected to the load, a friction-disk having planetary gears meshing with both the spur-gear and the internal gear, and a brake co-operating with said friction-disk whereby the load may be thrown gradually on the motor on starting.

DRILLING MACHINE.—No. 833,189; Richard Wheeler, Novinger, Missouri.

In a drilling machine, the combination with a rotary threaded drill-bar, of a worm-wheel constituting a seat therefor, a supporting-shaft for the worm-wheel, a bracket upon the shaft, driving mechanism including meshed gears upon the bracket and the drill-bar, a friction element having a threaded connection with the shaft for adjustment toward and away from the worm-wheel and provided in one face with an annular series of sockets, and a locking-pin carried by the bracket and capable of engagement with any of the sockets to adjustably lock the friction element.

APPARATUS FOR EXTRACTING GOLD.—No. 833,999; Joseph A. Comer, Los Angeles, California.

An apparatus for extracting gold, silver, and other metals from ores by a solution of cyanide of potassium, comprising

a series of settling-tanks communicating with each other, the cyanide-tanks, means for connecting said cyanide-tanks together, means for conveying the cyanide solution from the settling-tanks into the cyanide-tanks and from the cyanide-tanks again into the settling-tanks.

TUNNEL MINER'S POWER-SHOVEL.—No. 832,370; Patrick Ford, Chicago, Illinois.

A power-shovel embracing a car having its platform below the axle, a swinging boom extending forwardly therefrom at a slight upward inclination and a dipper having a short dipper-stick operated from said boom, means swinging said boom and a motor on the boom for actuating the dipper.

The Temple-Ingersoll Electric Air-Drill.

By FRANK RICHARDS.

This drill solves the perplexing and difficult problem of the employment of electricity for driving rock-drills. The problem may, indeed, be said to be solved indirectly, but none the less satisfactorily and completely. For this drill is not an electric drill, but an air-drill, as completely so as any air-driven drill ever invented, and indeed more so, since this drill cannot be driven by steam. While it is not an electric drill it is still driven by the electric current, which

Fig. 2. Sectional View.

is brought as close to the drill as possible to do the driving, and the drill apparatus when in use anywhere has no connection with its source of power except through the wires that are led to it.

Fig. 1 illustrates the Electric Air-Drill when in use, and Fig. 2 is a section exhibiting the construction. There is a drill cylinder quite similar to that of the ordinary air- or steam-driven drill. This cylinder is slid back and forth in a shell by a hand-operated feed-screw, and the shell is mounted upon a tripod, bar, or column in the usual way. The cylinder of this drill, while similar to that of the steam- or air-driven drill, differs from it in important particulars; it has no valves or valve-operating devices, no valve-chest or tortuous ports or passages, no buffers, no yielding springs and fastenings for the heads, nor the equivalents of these parts in any disguise of them. At each end of the cylinder there is simply an ample and free opening to which a hose may be attached. Provision is made for rotating the piston.

So much for the drill itself. Accompanying each individual drill is a little truck, which can be moved around anywhere as easily as the drill itself. Upon this truck are two small vertical single-acting air-cylinders with trunk pistons operated alternately by two cranks on a shaft below them, speed-reducing gears connecting the shaft with a small motor on the same truck. The upper end of one of these compressor-cylinders is connected by a short hose, six or eight feet long, to one end of the drill-cylinder, and the other end of the drill-cylinder is similarly connected to the other compressor-cylinder. It will be seen that the body of air contained in either end of the drill-cylinder, in its companion compressor-cylinder, and in the hose connecting them, has no chance to get out; it remains there constantly, provision being made for supplying leakage losses. Similarly, the two bodies of air in the two ends of the drill-cylinder and in the connections of each have no communication with each other; they remain distinct and intact.

This is the entire apparatus, and the operation is as simple as could be imagined. The air, to begin with, has a normal pressure in both lengths of hose and their connected cylinders of about 30-lb. gauge. If, now, the crank-shaft

turns and the piston in one of the air-cylinders advances, the pressure rises in that cylinder and in the end of the drill-cylinder to which it is connected, and, as the compressor-pistons work alternately, the pressure in the other cylinder and in the other end of the drill-cylinder falls, the difference of pressure on the two sides of the drill-piston causing it to make its stroke. When the movement of the compressor pistons is in the other direction the drill-piston makes its return stroke, and in this way, as the crank-shaft turns, the drill-piston makes its complete double stroke for each revolution, and this is kept up continuously as long as the motor runs and drives the cranks. The compressor-cylinders might more properly and less misleadingly be called pulsators, and this name they may in time acquire.

There are a number of important advantages connected with this arrangement. First, the great simplification. All the most complicated and costly parts of the drill are eliminated, such as the valves and valve-operating devices. Lubrication is simple and effective, an important particular in connection with it being that there is no exhaust to scatter the oil, which is used over again the same as the air. But the most gratifying feature in connection with the Electric Air-Drill is the fact that, compared with the standard air-driven drill, it *takes only one-third to one-fourth of the power to drive it*. This is due to the fact that the same air is used over and over, and that

Fig. 1. Drill in Operation.

all of its electric force is available in both directions, instead of exhausting the charge for each stroke at full pressure.

The builders of the drill, the Ingersoll-Rand Co., of New York, have so assured themselves of the great usefulness of the drill that they have made most elaborate and costly arrangements for manufacture of it. Three years of thorough testing, chiefly in Colorado, have demonstrated that it is a machine invaluable to the miner

Editorial.

THE COMPLETION of the first volume of *Economic Geology*, representing the eight numbers issued during twelve months, marks the end of the first stage in a most useful undertaking. Geology in its application to mining has secured a valuable friend in this semi-quarterly journal and we join with others in sending cordial congratulations to Mr. John D. Irving, the editor, and to his fellow-workers.

IN this issue we publish the concluding portion of Mr. P. Henry Argall's discussion of 'Metallurgical Accounts,' and while to some of our readers the space devoted to tabular statements may have appeared excessive, it will not seem so to smelter men, by whom the value of the article will be fully appreciated.

THE LONDON financial papers contain accounts of the Roi annual meeting, which amounted to a vindication of Mr. Anthony J. McMillan, the managing director, for a dividend at the rate of 3½ per cent was declared, good reports from the mine were submitted, and Mr. McMillan's friends were re-elected directors, and he was heartily thanked for his successful efforts.

IN ENGLAND also there is agitation for a Mines Department and recently a deputation consisting of the members of the Royal Commission on Coal Supplies called upon the Home Secretary in regard to it. A bureau subordinated to the Home Office is not considered enough and it is urged that there be created a separate department, as is the case with agriculture, and woods and forests. *The Mining Journal* has advocated such a step for many years and we congratulate our London contemporary on the prospects of success, for the Home Secretary made an encouraging response to the deputation mentioned.

APPARENTLY we are "thru" with the effort to impose spelling reform by ukase. Congress has voted "to adhere to the standard of orthography prescribed in generally accepted dictionaries of the English language." For this relief, much thanks. In the meanwhile, we do not envy the feelings of those hasty editors, who, mainly to obtain notoriety, accepted the unauthorized dictum of the Spelling Board, even though supported in a characteristically impulsive manner by Mr. Roosevelt. Spelling reform will come not *per saltum*, nor by ukase, nor by a self-constituted committee, but by the usage adopted in the columns of the leading newspapers of the English-speaking world and those are *The Times* of London, *The Evening Post* of New York, the *Star* of Montreal, the *Argus* of Melbourne, and a few others.

Leasing Discredited.

The leasing system has been responsible for the successful development of many mines and even of mining districts. In Clear Creek and Gilpin counties, Colorado, it has kept alive those mining centres during times of depression, and it has revived mines apparently exhausted of their ore reserves. Later, at Cripple Creek, lessees have proved themselves good prospectors underground, and economic operators at surface. Here, also, when the engineers and managers of several mines had come to the conclusion that operations by the company could no longer be profitable, the old workings have been leased to enterprising groups of miners, usually with favorable concessions in case of exploratory work in new ground. This policy has justified itself. At Stratton's Independence, especially, after the highly technical management had confessed that they could no longer earn dividends, the big mine was subdivided into leases and the result was a profit in royalties of \$500,000 per annum. But here comes one of the darker sides of the subject, for it is fairly certain that some—it is impossible to estimate how much—of this phenomenal success in finding ore by the lessees was due to the concealment of rich streaks cut by them while in the employ of the company and that their ability to get on the track of rich ore was not all to their credit as miners. On the whole, however, it is fair to say that in many big mines the company's engineers and superintendents do not spend enough time underground, and thus they render possible these *caches* that become the plums of lessees subsequently. In districts where veins are rich, small, and erratic, systematic exploration is less successful than constant watching of signs and changes understood by experienced miners, so that the leasing system becomes best suited to the local conditions. Such is the case in the new goldfields of Nevada, where many of the best discoveries are due to lessees. At Goldfield particularly many of them have made fortunes, by their enterprise, their luck, and by their skill also. There the lodes are not necessarily small, but they are rich, often ill-defined, and frequently erratic, so that the miner must keep his nose to the streak. The mine owners of Nevada owe a great deal to the leasing system and it is regrettable therefore that it is being discredited at this time by the practices current at Goldfield. Owing to the near expiration of some of the best leases, there has been a great hurry to get out the rich ore, with the result that the mines are being deliberately gutted. At the same time timbering has been neglected until there is danger of fatal accidents, and ore stealing has become general. As the lessees cannot run the risk of a strike by compelling a search of the mine workers, they have made no effort to stop pilfering. At the Selby smelter there are 68 sacks of ore valued at \$100,000 from the Mohawk mine, for which suit has been begun (by the company owning the mine) on the ground that it was stolen. It is claimed that as much as \$300,000 has been taken from this property alone during the past month by ore thieves, employed as miners. The lessees are aware of the identity of some of the men but dare not discharge

them, for fear of a strike. Such a state of affairs is highly discreditable. The lack of timbering and the obvious absence of proper supervision could be corrected by a State Mine Inspector, as was done at Cripple Creek, where the Bureau of Mines did excellent service in this regard. Certainly, it is not a pleasant picture to contemplate, of mines operated by a mob beyond the control of the responsible parties and of leasing methods that have degenerated into mere gophering. In every respect it is contrary to the best traditions of mining.

Reform and Education.

In this issue, under 'By the Way,' a page reserved each week for notable statements by thoughtful men, we publish a portion of the President's message to Congress. Mr. Roosevelt is always interesting, and he is so thoroughly in touch with the better spirit of the country of which he is the chief executive, that his utterances invariably command attention. The portions we have selected deal with the relations between labor and capital, and systematic education. His arraignment of sinister demagogues obviously refers to one of them in particular who received a severe lesson during the recent election, but it applies to a good many others who make a business of being reformers. Certainly nothing is worse for a great industrial community than the breeding of hatreds and misunderstandings between employers and employed. From the standpoint of mining we know that economical work cannot be done unless there is a certain feeling of confidence and respect between the manager and his men. Strikes and lock-outs are due too often to the sudden promotion of those who never learned to obey and are therefore not likely to know how to command. Mutual consideration is necessary if the vast machinery of industrial progress is to work smoothly. The President says what he has to say in a plain way and it will be well to read his statement carefully. In regard to education, in particular the systematic education that is to bring about national "success," he speaks with equal conviction, but we are not so certain but that the people of these United States need advice how to be happy just as much as they do how to be effective—when effectiveness is measured solely by bread-winning and money-getting capacity. There are plenty of people to advocate a sound technical education and there are so few to emphasize the fact that the size of a salary is neither the measure of a man's happiness nor of his usefulness; therefore we venture to make a plea for the broad education—as against mere instruction—that makes better citizens and better heads of families, that makes all-around men instead of narrow specialists with a capacity to gather shekels from under the feet of opportunity. We have reached a measure of industrial effectiveness far ahead of Europe and we have paid for it—as everything worth having is paid for—in the loss of some of the things that make for happiness. The instruction that makes clever engineers and ingenious mechanics is worth something, but the education that cherishes moral worth and teaches youth to think clearly is worth more.

By the Way.

IN his recent message to Congress, the President said :

As a nation we still continue to enjoy a literally unprecedented prosperity; and it is probable that only reckless speculation and disregard of legitimate methods on the part of the business world can materially mar this prosperity.

In dealing with both labor and capital, with the questions affecting both corporations and trades unions, there is one matter more important to remember than aught else, and that is the infinite harm done by preachers of mere discontent. These are the men who seek to excite a violent class hatred against all men of wealth. They seek to turn wise and proper movements for the better control of corporations and for doing away with the abuses connected with wealth, into a campaign of hysterical excitement and falsehood in which the aim is to inflame to madness the brutal passions of mankind. The sinister demagogues and foolish visionaries who are always eager to undertake such a campaign of destruction sometimes seek to associate themselves with those working for a genuine reform in governmental and social methods, and sometimes masquerade as such reformers. In reality they are the worst enemies of the cause they profess to advocate, just as the purveyors of sensational slander in newspaper or magazine are the worst enemies of all men who are engaged in an honest effort to better what is bad in our social and governmental conditions. To preach hatred of the rich man as such, to carry on a campaign of slander and invective against him, to seek to mislead and inflame to madness honest men whose lives are hard and who have not the kind of mental training which will permit them to appreciate the danger in the doctrines preached—all this is to commit a crime against the body politic and to be false to every worthy principle and tradition of American national life. Moreover, while such preaching and such agitation may give a livelihood and a certain notoriety to some of those who take part in it, and may result in the temporary political success of others, in the long run every such movement will either fail or else will provoke a violent reaction, which will itself result not merely in undoing the mischief wrought by the demagogue and the agitator, but also in undoing the good that the honest reformer, the true upholder of popular rights, has painfully and laboriously achieved. Corruption is never so rife as in communities where the demagogue and the agitator bear full sway, because in such communities all moral bands become loosened, and hysteria and sensationalism replace the spirit of sound judgment and fair dealing as between man and man. In sheer revolt against the squalid anarchy thus produced men are sure in the end to turn toward any leader who can restore order, and then their relief at being free from the intolerable burdens of class hatred, violence, and demagoguery is such that they cannot for some time be aroused to indignation against misdeeds by men of wealth, so that they permit a new growth of the very abuses which were in part responsible for the original outbreak. The one hope for success for our people lies in a resolute and fearless, but sane and cool-headed, advance along the path marked out last year by this very Congress. There must be a stern refusal to be misled into following either that base creature who appeals and panders to the lowest instincts and passions in order to arouse one set of Americans against their fellows, or that other creature, equally base but no baser, who in a spirit of greed, or to accumulate or add to an already huge fortune, seeks to exploit his fellow Americans with callous disregard to their welfare of soul and body. The man who debauches others in order to obtain a high office stands on an evil equality of corruption with the

man who debauches others for financial profit; and when hatred is sown, the crop which springs up can only be evil.

The plain people who think—the mechanics, farmers, merchants, workers with head or hand, the men to whom American traditions are dear, who love their country and try to act decently by their neighbors, owe it to themselves to remember that the most damaging blow that can be given popular government is to elect an unworthy and sinister agitator on a platform of violence and hypocrisy. Whenever such an issue is raised in this country nothing can be gained by flinching from it, for in such case democracy is itself on trial; popular self-government under republican forms is itself on trial. The triumph of the mob is just as evil a thing as the triumph of the plutocracy, and to have escaped one danger avails nothing whatever if we succumb to the other. In the end the honest man, whether rich or poor, who earns his own living and tries to deal justly by his fellows, has as much to fear from the insincere and unworthy demagogue, promising much and performing nothing, or else performing nothing but evil, who would set on the mob to plunder the rich, as from the crafty corruptionist, who, for his own ends, would permit the common people to be exploited by the very wealthy. If we ever let this Government fall into the hands of men of either of these two classes we shall show ourselves false to America's past. Moreover, the demagogue and the corruptionist often work hand in hand. There are at this moment wealthy reactionaries of such obtuse morality that they regard the public servant who prosecutes them when they violate the law, or who seeks to make them bear their proper share of the public burdens, as being even more objectionable than the violent agitator who hounds on the mob to plunder the rich. There is nothing to choose between such a reactionary and such an agitator; fundamentally they are alike in their selfish disregard of the rights of others, and it is natural that they should join in opposition to any movement of which the aim is fearlessly to do exact and even justice to all.

It is probable that a thoroughly efficient system of education comes next to the influence of patriotism in bringing about national success of this kind. Our federal form of government, so fruitful of advantage to our people in certain ways, in other ways undoubtedly limits our national effectiveness. It is not possible, for instance, for the National Government to take the lead in technical industrial education, to see that the public-school system of this country develops on all its technical, industrial, scientific, and commercial sides. This must be left primarily to the several States. Nevertheless, the National Government has control of the schools of the District of Columbia, and it should see that these schools promote and encourage the fullest development of the scholars in both commercial and industrial training. The commercial training should in one of its branches deal with foreign trade. The industrial training is even more important. It should be one of our prime objects as a nation, so far as feasible, constantly to work toward putting the mechanic, the wageworker who works with his hands on a higher plane of efficiency and reward, so as to increase his effectiveness in the economic world, and the dignity, the remuneration, and the power of his position in the social world. Unfortunately, at present the effect of some of the work in the public schools is in exactly the opposite direction. If boys and girls are trained merely in literary accomplishments, to the total exclusion of industrial, manual, and technical training, the tendency is to unfit them for industrial work and to make them reluctant to go into it, or unfitted to do well if they go into it. This is a tendency which should be strenuously combated.

Secret Reserves.—Gold Production Increasing.—Interesting Details.
—The Rand at Its Zenith.—Coolie and Native Labor.—The Diamond Boom.

A complete change has come over the Rand, as far as reserve gold is concerned. In last month's returns almost every producing mine published the amount of gold held in reserve. Not many mines are without a reserve. The amounts differ a great deal, from a hundred or so ounces on the poor mines, to 10,000 oz. on the rich mines of the Central Rand. Now that everything is made public, there is not much use to have a reserve at all. People seem to think it sacrilegious to use any of the reserve. They consider it something to look at. A decrease in reserve is contemplated with more apprehension than a fall in profits. Provided the reserve is not abused, as it never has been on the Rand, there is no reason why it should not be secret. It is almost impossible to keep the profits uniform without a reserve.

The returns for October show that another record is established for the Transvaal. The figures show that the total production, inclusive of 14,968 oz. gold reserves,

least on the Central Rand will fall out of line. A few of the big producers will soon enter the down-grade in production. New mines will come forward, to be sure, but as the deep levels are poorer than the outcrops, the outlook for continued record-breaking is not bright. The Rand is probably near its zenith now, as a gold producer. As regards native labor, the figures furnished by the Chamber of Mines for October disclose an improvement in the number of natives distributed compared with time expired and wastage. The number of natives employed at October 31 was 80,316 as compared with 77,858 in September, and 76,246 at the end of August. Of Chinese indentured labor 52,080 were in the employ of mines on August 31, 53,400 at the end of September, while on October 31 the number returned was 53,134.

The diamond boom continues. Syndicates for the exploitation of diamonds are formed nearly every week, there is a 'flare up' for a week or so, and then the thing collapses. The Orange River Colony is the favorite hunting ground for the diamond promoters, on account of the favorable diamond mining law in that region. Some of these syndicates have been out and out swindles, but so far there have been no prosecutions. In this diamond flutter the public seem content to consider any hole in the ground a diamond mine, whether it contains gem-stones or not.

Joplin, Missouri.

Production of Zinc and Lead Ore.—Shortage of Cars.—Thomas C. Co. Doing Well.—New Company Formed to Prospect.—Several Strikes of Ore.—General Activity and Prosperity.

The highest price reported paid for zinc ore last week was \$49.70 per ton for the ore from the Engineers Zinc Co. at Webb City. The highest price reported paid for lead ore was \$84 per ton, a weakening of \$1.50 as compared to the price of the previous week. The zinc ore shipment last week shows an increase of 450 tons and of lead ore 11 tons over the previous week, with an increase in value of \$16,390. Compared with the same week last year the shipment is 403 tons of zinc greater and 69 tons of lead less, with a gain in value of \$10,800. The shipments last week were: Zinc ore, 10,585,140 lb., valued at \$231,800; lead ore, 1,331,050 lb., valued at \$54,060; combined value, \$285,860. For the 49 weeks the shipments have been: Zinc ore, 524,135,950 lb. valued at \$11,334,687; lead ore, 73,111,850 lb., valued at \$2,832,362; combined value, \$14,167,049. Up to the first of this month it seemed certain that the total value for the district for the year 1906 would go beyond the fifteen million mark, but the great scarcity of cars makes it look a little doubtful just now; however, should the buyers be able to get the cars the record mark will surely be made.

The Thomas C. Mining Co., owners of a lease of 20 acres of the Four Hundred Prospecting Co.'s lease on the Schifferdecker land near Scotland, southeast of Duenweg, is now opening what promises to be one of the best mines in that part of the district. The company is driving at the 100-ft. level and has a face of zinc and lead ore 14 ft. high. The water supply is very short in that locality, and as soon as the company has more fully developed the size of the orebody, it is intended to commence drilling a deep hole for water in order to be able to clean the ore that is being taken out of the ground. At the depth of the present working, there is not enough water to keep one hand-jig supplied. An assay on the cuttings from the drill showed 20% zinc and lead, and the dirt now being hoisted shows about the same. The parties composing the Thomas C. Co. are all residents of Joplin and the mine was named after Thomas Connor, one of the owners.

A company composed of George C. Meece and Harry

Map of South Africa.

was 540,609 oz. fine gold, of the value of £2,296,361, which is an increase compared with the September yield of 35,498 oz., valued at £150,786. October results present several features of interest. Two groups, Albu and Goerz, have declared all their reserve gold as profits, and in future will have no reserve. A remarkable record was made by the premier gold producer, the Simmer & Jack, which in October turned out gold to the value of £100,157. This mine is run almost entirely with coolie labor, and the splendid results obtained show what a success the Chinese are. During the month there were at work 8,370 stamps in the Transvaal, an increase of 55 over September. Of the total, 7,975 stamps were working on the Rand and 395 in outside districts. The three leading producers in October were the Simmer & Jack mine, which with 320 stamps crushed 62,010 tons, for a value of £100,157; the Robinson mine, with 210 stamps turned out £91,237; the Cason, which with 220 stamps crushed 36,500 for a recovery of £77,564. The amount of waste rock sorted out varied a great deal on the different mines, from no sorting in the case of the Langlaagte Consolidated, to 29% in the case of the New Rietfontein mine.

Many people speculate how much longer this breaking of records can continue. Before long one producer at

Scherle of Joplin and several Kansas City parties has been formed to prospect on a 200-acre tract of land situated two miles north and one mile east of Carl Junction, owned by Jesse G. Starr, buyer for the Lanyon Zinc Co. in Joplin. The company has secured a drilling outfit and will let a contract for 1,000 ft.—Col. H. H. Gregg and others of Joplin, who have a lease on 40 acres of land in the northern part of Newton county, just south of Joplin, have succeeded in getting their shaft down to the ore and will soon begin making shipments. A number of drill-holes have been put down on the land and some good runs of ore were found.—The Good Day Mining Co. of Webb City has filed articles of association with a capital stock of \$80,000, divided into 800 shares of the value of \$100 each, all paid up for a term of 50 years.

The Alice of Old Vincennes Co., composed of Joplin, Vincennes, and Evansville (Ind.) parties operating on a 40-acre lease of the Schifferdecker land, west of Chitwood, has opened a rich run of ore at the 160-ft. level. A shaft is being sunk and is now down to a depth of 60 ft., and while the sinking is going on a modern 150-ton concentrating plant is being erected. It is expected the shaft will be in the orebody by the time the mill is completed and ready for operation.—The Moss mine at Alba, on the Rochester Land & Leasing Co.'s land, is being operated by several Webb City parties, who are highly pleased with the showing the mine has made since it began producing a short time ago. The weekly turn-in for the four weeks in November was: 71, 72, 87, and 78 tons, and the first week in December 107 tons, and this was done with only a single shift with a 150-ton mill. George Hardy of Webb City is manager of the company.

Bisbee Arizona.

The Strike in the Denn-Arizona. — Importance of the Discovery. — Details of the Occurrence. — Scarcity of Fuel. — Operations Crippled. — Shattuck-Arizona Meeting. — Another Smelter. — Development Work.

The feature of the week in the local mining field has been the strike of ore in the Denn-Arizona property, and it is looked upon as one of the great events in the history of the Warren mining district. The importance of finding ore in that part of the district where the Denn is located lies mainly in the fact that it is the first permanent orebody discovered in a portion of the camp where several million dollars have been expended without any encouraging results. Adjoining the Denn on the south-east is the American-Saginaw property, which is being operated by the Cole interests. To the south of the Denn is the Junction property, now included in the Superior & Pittsburgh holdings. The discovery of ore in the Denn at the place where it was found is really more important to the Junction than to any of the other surrounding properties, as the trend of the ore would indicate that it is an extension of a body that lies closer to the surface in the latter property. At the present time the Denn shaft has been sunk to a depth of 1,100 ft. At the 1,000-ft. level a station was cut, and a drift driven in the direction of the Saginaw-American property, the object being to connect both shafts as the Saginaw was also driving toward their side-line. When the drift had been pushed forward 600 ft. it was decided to run a cross-cut south and a little bit west to strike the diamond-drill bore. This cross-cut was driven 228 ft., when a round of shots opened up a full face of oxide and carbonate ore. Work was pushed forward vigorously, and at the present time 34 ft. have been passed through, and the face, floor, sides, and roof of the drift are still in the formation. The most competent experts in the district are of the opinion that a persistent orebody has been uncovered. Sinking of the shaft at

this property is still going on, but no developments of importance have happened at that point.

During the past two weeks the fuel situation has become very embarrassing in the district, and on account of this condition the Calumet & Pittsburgh shaft of the Superior & Pittsburgh Co. was forced to close down, as well as the Hoatson shaft belonging to the same company. The fuel famine has also been felt by the Calumet & Arizona Co., but up to the present time they have not had to close down any shafts. Oil is used generally throughout the district as fuel, but in the present juncture most of the properties are being operated with coal. It was thought for a while that it would be necessary to close down the smelters, but a limited supply of oil has

Map of Arizona.

been secured, and fears on this account are practically allayed.

At the Shattuck-Arizona the regular shipments of ore to the smelters are being materially increased, now that the new Allis-Chalmers hoist has been put in operation. A number of the Shattuck directors were here a week ago, and made arrangements for the regular annual meeting, which will be held here during the first week in January. The striking of the ore at the Denn, which property is controlled by practically the same crowd, removes all doubt of the construction of a smelter for these properties, and it is stated on competent authority, that arrangements for the erection of a smelter at once will be made by the directors at their annual meeting.—At the Cochise property the principal work being done is on the 300-ft. level in the drift, where a streak of ore was encountered some time ago. During the past week this streak has been followed for a distance of 12 ft., and the showing at the present time is most encouraging.—In the Huachuca district the Butte & Arizona and Princeton companies are pushing development work with all energy, but there have been no developments of an important nature.—Capt. D. A. Duncan, one of the owners of the Chiricahuaua property, in the Chiricahuaua mountains, has gone East for the purpose of consummating a deal for the development of the property, which has been declared to be valuable in spite of the slovenly manner in which it was handled.

Butte, Montana.

Strike in the Ophir.—*Extracting Copper From Mine Water.*—*Important Development in Alliance Mine.*—*New Incorporations.*—*Copper Prospects in Beaverhead County.*—*A Local Mining Exchange.*—*Butte Exploration.*—*Rich Ore in the Eagle.*—*Prospecting the Trifle Claim.*—*Other News.*

The strike made in the Ophir mine; owned by the Butte Central & Boston Copper corporation, has been demonstrated to be of an important character. The vein was first opened on the 300-ft. level, and has now been thoroughly opened at a depth of 500 ft.; it contains at that point seven feet of solid ore carrying 7% copper, and 300 oz. silver. The vein is separate from the original Ophir lode. There are now three known veins in this ground, one north and the other south of the one just cut on the 300 and 500-ft. levels. The north vein has an orebody 18 ft. wide; the south vein will be reached by a cross-cut being run from the 300 after going about 150 ft. farther. The foundation for the new 500-h.p. engine has been completed, and the superstructure is being made. The engine will be in position by Christmas.

The Butte & Superior Copper Co., owned principally by Duluth men, has begun sinking on the Black Rock shaft, and will take it to a depth of 1,200 ft. before any cross-cutting will be done. The shaft was 500 ft. deep, but the new company had to enlarge it and re-timber it from top to bottom with heavier material in order to make it fit for the deep work contemplated.—Frank H. Probert, the mining engineer who made an exhaustive study of the copper precipitating methods employed at the Rio Tinto mines several years ago, has just completed an examination of the plant of the East Butte Mining Co., and tests of the copper waters and tailing deposit on the company's ground. He says the East Butte plant is a crude affair, but it is one of the company's important earning features. He finds there is sufficient of the copper-bearing water to warrant the erection of a large and permanent plant, such as is in use at the Rio Tinto mines.—From tests that he made, Mr. Probert estimates that there are available 2,000,000 lb. copper, and that the supply is practically continuous. The water coming from a number of mines flows over the East Butte deposits, and leaves its copper to be added to the red metal that has been accumulating there for many years. A new and larger precipitating plant is being erected by lessees. The precipitating enterprise is a big source of revenue to the East Butte Co., as it gets a royalty of 25% without a dollar in outlay.

The Colusa-Leonard Extension Mining Co. has completed its new surface plant and sinking on the shaft has been resumed. The shaft was 75 ft. deep when work was stopped, in order that the new engine and boilers might be installed. The company owns a number of mining claims east of the Leonard and Colusa mines, of the Boston & Montana Co., that are considered to be in a good location. The development work is under the direction of William MacPherson. The company owns 47 acres of ground, comprising almost an exact square.—The Butte-Montana Co., which has the Alex. Scott and Annie claims under bond, reports another strike of rich copper ore in a cross-cut south of the 600-ft. station of the Alex. Scott. The company is also trying to sell enough treasury stock to make a payment on the bond, which will soon be due. Operations have always been hampered by a lack of funds. The Alex. Scott is a fractional claim lying just north of the Dayton and Colusa mines of the Boston & Montana Company.

The Alliance Copper Co. has not yet determined the width of the orebody struck by it at a depth of 200 ft. a week ago, but the vein has been cut at another point,

which proves it to be extensive; the ore has been cut into for 30 ft., and it is of high grade, a good portion being bonanza. The vein extends into the ground of the Farrell Copper Co., and undoubtedly will be found to extend through adjoining ground and the property of the East Butte Co., farther east.—The North Alice Mining Co. has been organized and incorporated with a capital stock of 1,000,000 shares at \$1 each. Its incorporators and directors are Dennis Driscoll, Thomas McTague, John N. Bielenberg, M. O'Donnell, Richard K. Dwyer, E. Driscoll, and John E. Corette. The property of the company is north of the town of Walkerville.—Some Butte men are developing the Guy group of copper claims in the Elkhorn district of Beaverhead county. A shaft 150 ft. has been sunk, and at a depth of 30 ft. it passed through a 30-ft. vein from which some copper glance was taken. A cross-cut is being run from the bottom of the shaft. It is claimed that the formation of the district is similar to that of Butte. A number of other copper prospects in the Elkhorn and Argenta districts of Beaverhead county are being developed by Butte capital.

For the first time in its history Butte will soon have a mining exchange in operation. A company has been organized and incorporated with a capitalization of \$20,000, and the following board of directors: E. L. Mayo, of the brokerage firm of Mayo, Sachs & Co.; R. A. Carnochan, of the United Copper Co.; J. H. Vivian, president of the Butte & Arizona Mining Co.; W. C. Lewis, president of the National Mining & Investment Co.; A. T. Morgan, capitalist; M. S. Largey, banker; C. F. Kelley, of the legal department of the Amalgamated Co.; H. B. Byrne, Butte manager for Paine, Webber & Co.; John N. Kirk, lawyer and mining man. The subscribers are all prominent bankers, mining, professional, or business men.—The Butte-Potosi Mining Co. has been organized to work some silver claims near Potosi, in Madison county. The incorporators and directors are W. H. Young, and Joseph Farrell, of Pony; J. K. Heslet, Charles Schatzlein, and J. L. Templeman, of Butte. The company is capitalized for \$1,000,000.—The Cleveland-Montana Mining Co. is one of the new organizations that is engaged in intelligent development work in the Butte district. Its properties are situated far up the side of the main range of the Rocky mountains, about six miles southeast of Butte. An adit is in about 500 ft., and is approaching a point where the company expects to cut a vein.—The drift being run north from the 1,000-ft. station of the Butte Exploration shaft on the Six O'Clock claim has been advanced over 100 ft. The ground is full of copper pyrite, and the indications are encouraging, although the expectation to find a small vein within 75 ft. of the shaft was not realized. The first big vein, which shows a surface outcropping, is expected to be found in the cross-cut between 200 and 300 ft. from the shaft. As there are no openings on the vein at all, its dip is unknown. It is believed to dip south and toward the shaft, though it may be found to dip north, as other veins in that vicinity are known to do.

Assays of the ore struck recently in the Eagle mine, north of Walkerville, gives 175 to 330 oz. silver, with an average of about 250 oz. per ton.—The East Butte Extension Copper Co. has taken up the deeds to the ground on which No. 1 and 2 shafts are situated, paying cash. The price was \$85,000. The ground adjoins that of the Alliance and Farrell companies. Regular shipments of ore are being made from two of the shafts of the Extension Co.—The shaft being sunk by the Butte Copper Co. on the Trifle claim has reached a depth of 375 ft., and will be carried to the 1,000-ft. point as rap-

idly as possible. No development work has been done in the Trifle above the 300 level, but at that point some work was done on the vein, which was encountered 207 ft. from the shaft. The vein has been opened for a distance of 105 ft.; it is 44 ft. wide from wall to wall, and the orebody, which is continuous for the 105 ft. exposed, is 11 ft. wide. The ore is rich in silver and galena, and carries a good percentage of copper. Another vein carrying 10 ft. of 2% copper, and 15 oz. silver, has been cut in the Trifle shaft.

London.

Two New Issues.—The Russian Mining Corporation.—South Mount Boppy.—The Sudan Goldfield.—Indian Mining.—More Cornish Flotations.—Pseudomorphs of Tin After Feldspar.—Exacting Landlords.—Mexican Mines.—Ore-treatment at Stratton's Independence.

The week has been marked by two new mining issues of some importance, examples in their way of the diversity of aim and character of British enterprise. The Russian Mining Corporation, Ltd., has made its appearances under the auspices of the Venture Corporation, with the co-operation of the Consolidated Goldfields of South Africa and other powerful London financial groups. The share capital is £153,750, divided into 150,000 ordinary shares of £1 each and 75,000 deferred shares of 1s. each. The present issue consists of 75,000 ordinary shares and 75,000 deferred shares, which have all been privately subscribed. The ordinary shares in the original capital entitle the holders to be recouped by way of preferential dividend all capital (not being premium capital) from time to time paid up on such shares. After the rights of such shares shall have been satisfied, the divisible profits of the Company shall be distributed as to one-half by way of dividends on the share capital of the Company for the time being issued other than the deferred shares, and as to the other half by way of dividends on the deferred shares *pari passu*. The Company has already established an influential connection in Russia.

The other flotation in question is the South Mount Boppy Gold Mining Co., Ltd., an off-spring of the Mount Boppy Co., both being under the management of John Taylor & Sons. The capital of the new company is £150,000 in £1 shares, the purchase consideration being £90,000 (to be satisfied wholly in fully paid shares) and the working capital is £60,000. In the leases acquired, which adjoin the Mount Bobby property to the south, a continuation of the Mount Bobby lode is expected to be found. It has already been traced to within 490 ft. of South Mount Boppy's northern boundary, and, according to its present trend, should be found on four of the latter company's leases for a total length of over 3,000 ft. Prospecting operations to the south of Mount Boppy Co.'s property have shown the lode to be persistent, varying in width up to 10 ft., and auriferous, and it is stated that the manager is confident of the best results being attained in depth. Through the leases lying to the southeast is a lode that appears to run parallel with the main Mount Boppy lode, and which has assayed from about 2 dwt. up to 32.67 dwt. per ton of quartz. Mr. William Frecheville took a sample from a trench that gave an assay of 8 dwt. 3 gr. per ton for a width of 1½ ft. "An encouraging result," he remarks, "which should be followed up." The company will, therefore, have two lodes to develop, either or both of which may equal in importance the one now being so profitably worked by the Mount Bobby Co. It is proposed to sink a shaft to find the main lode in the South Mount Boppy Co.'s leases, and also to put down a shaft to the southeast upon the parallel lode. This work will be under the supervision of Mr. Thomas Pascoe, the superintendent of the Mount Bobby mine. The record of

the parent—Mount Boppy—company is encouraging as an indication of the possibilities of its offspring. During the seven years of the company's existence 199,434 tons of ore have been crushed for a yield of 142,256 oz. gold, of the value of £436,237; thirteen dividends have been paid amounting in the aggregate to 161½%, or £183,632, the distribution for 1905 being the largest ever made, namely, 47½%; and on December 31 last the reserves of ore, although the mine is at present no more than about 400 ft. deep, were estimated at 182,000 tons—more than three years' mill-supply—containing a profit of about £230,000, or nearly double the amount of the nominal capital. The lode is of great width, exceeding 50 ft. in places, and rarely falling below four or five feet; consequently large masses of ore are opened out within a comparatively limited area.

In quite a different field of operation, but also under the efficient management of John Taylor & Sons, the Su-

Eastern Australia.

dan Goldfield, which publishes its second annual report, is considered to present indications that point to a very good mine being ultimately opened up. On the Om Nabardi property several shafts have been sunk down to the water-level with fair results. The most encouraging development has taken place in the No. 2 air-shaft. At 210 ft. deep the vein is 4 ft. wide and assays 3 oz. per ton. At the 120-ft. level the vein was only 9 in. wide, going 15 dwt. per ton. The increase in width to 4 ft. and in value to £12 per ton is evidence that the lode is improving in depth. Development has been hampered recently by the lack of pumping apparatus, the management desiring to be sure of their ground before ordering expensive machinery. The vein has been traced along its outcrop for a length of 2,000 ft., while the 120-ft. level has been driven for the whole distance. The installation of the necessary machinery will allow the driving of a level at 240 ft., and when this is fully connected the ore disclosed may justify the erection of a battery. Conditions are favorable for working, water being plentiful and labor so abundant "that we have been able to pick our men."

Another company under the same management, the Champion Reef, in the Mysore district of India, has issued

its eighteenth annual report to Sept. 30. It states that, including a net balance brought forward of £7,668 and £567 dividend from the Kolar Mines power station, a total sum of £349,844 is shown at credit of profit and loss. Two interim dividends of 9d. per share each, amounting together to £156,000, have been paid; £20,978 is retained for income tax; £10,134 is set apart for depreciation of machinery, plant, etc.; £5,000 has been distributed in accordance with the resolution of the shareholders, and £76,000 is appropriated toward the expenditure on shafts, buildings, etc. A disposable balance of £81,731 then remains, out of which the directors recommend a final dividend of 9d. per share, carrying forward £3,731. The total amount distributed out of the year's profit will then be £234,000 or 2s. 3d. per share, equal to 90% upon the nominal capital. A total of 203,174 tons of quartz were crushed, and 150,633 oz. bar gold were produced—an average yield of 14 dwt. 20 gr. per ton; and 207,143 tons of tailing and slime were treated by the cyanide process, resulting in the recovery of 27,008 oz. bar gold, equal to 2 dwt. 15 gr. per ton. The total return of 177,641 oz. realized £678,706. The stock of tailing from the old mill at the No. 2 cyanide works is nearly consumed; but there is a large accumulation of sand at the No. 1 mill available for treatment, in view of which the capacity of the No. 1 cyanide plant has been increased. Latterly, over 19,000 tons of tailing and slime per month have been dealt with, and as further additions are being made to the No. 1 plant it is anticipated that this tonnage will be maintained. Regarding developments: On the East Reef, which has been extensively developed in Garland's section, the results have been disappointing; for though the drivages and winzes over great lengths have showed strong, regular quartz from two to four feet wide, the value has been so low that the ore developed could not be included in the reserves of stoping ground. The reserves of ore are computed by Mr. Arthur Gifford at 383,071 tons, an increase of 4,155 tons upon the estimate of last year. He states that: "The main reef has been recently intersected at the deepest points at Garland's Carmichael's and Rowe's shafts, and though no great improvement is yet shown at these points, the continuity of the lode in depth has been proved, with about the same width and value as at corresponding points in the levels immediately above." At Carmichael's shaft the drivages on the lode at the lowest level—the 2,940 ft.—show a width of 2 ft. 3 in. and a value of 19 dwt. 8 gr. of gold per ton, while at Rowe's the deepest level there has disclosed some rich quartz near the northern boundary, demonstrating that shoots of higher quality hold down to the deepest points worked. For these reasons the directors feel that they have strong reasons for looking forward to the opening up again of ore of better quality.

The Western Tin & Copper Syndicate has been registered with a nominal capital of £50,000 in £1 shares "to acquire and turn to account any tin, copper, coal, iron, or other mines, rights, and metalliferous lands in Cornwall or elsewhere." The first operation of the Company will be to unwater an important group of mines recently acquired after somewhat prolonged negotiations. There is to be no initial public issue of shares, the group which has subscribed the necessary capital deeming it best to first unwater the property, and, so far as possible, demonstrate its value before asking the public to take any financial interest in the concern. Information is forthcoming from St. Agnes of the registration of a company to work Wheal Coates, a tin and copper proposition, worked on a small scale over a century ago. The last company ceased operations in 1884, when the tin standard was £71. The last sale at the ticketing was in November of that year, a small parcel of black tin fetching £42 per ton. The average produce for many years was about 20 lb. tin

per ton of stuff. The main lode is nearly vertical—slightly underlying south and outcrops in the cliff. The underground operations extend a good way under the sea. Both engine-houses and the stamps were on the cliff. Wheal Coates has gained some notoriety by the fact that in this mine were found pseudomorphs of tin after orthoclase. They were found in the form of crystals, the same shape as the crystals of feldspar that are seen in granite. It is believed that this is the only case in the world in which tin has been found in this form. Wheal Coates suspended operations because of the low price obtaining for tin; while a small pit-work was overpowered by an abnormal quantity of water let out by a newly cut lode. Some excitement among local miners and others (writes a *Western Morning News* correspondent) has been caused by the recent discovery of a rich tin lode on the South Wheal Leisure mining property, owned by Mr. Stuart Bailey, of Perranporth. At 20 ft. from the surface a tin lode was found, some stones from which were crushed and vanned by Mr. F. Penna, who judged it to go about 1 to 1½ cwt. black tin per ton of lode-stuff; value £5 to £7. This rich find is not surprising, as the locality was well known to the 'old men,' judging from the innumerable 'pits' and 'burrows' along the backs of the lodes, where these ancients worked for tin. Although the labor question is not yet serious in the Redruth and Camborne districts, it may become so sooner than some think, and mine directors may do worse than give some attention to the matter. The *Mining World* considers that it will be interesting to note to what extent the ground landlords will come forward, more particularly in granting plots of land to miners upon which to build cottages of their own. There are many instances in the mining districts of men who helped their fathers to build cottages on the life system, who have been exasperated at seeing these cottages go back to the ground landlord, from whom they must buy back should they desire to live in them. It is therefore little wonder that the miner leaves the place of his birth, and the landlords will be wise to consider this matter, for the longer it is delayed the more exacting the terms will ultimately be.

A special cable dispatch from the City of Mexico to the *Financial News*, says: "The San Francisco del Oro has struck a remarkably rich vein, promising great results, and has also struck a permanent water supply, thus rendering easy the erection of its own mill and proving of untold benefit to the Company. The entire district is interested, with the result that a keen demand for the shares has commenced." This news will help the growing interest in the shares of the Company. A year ago they might have been bought for one shilling, today they are a good market at about 21s. Apropos of Mexican mines, the story is told of the jobber who having taken a literary lady into dinner recognized, for a time, that the conversation was a little out of his depth, and was accordingly glad when a subject was at last introduced on which he felt qualified to pass an opinion. "What do you think of the future of Esperanto, Mr. Smith?" she asked. "Risky, of course; like all those American mines," he promptly replied; "but if the rich shoot holds out I'd sooner be a bull than a bear at present prices."

Some little time back it was mentioned in my correspondence that the dump and low-grade ore treatment at Stratton's Independence was about to enter upon a new phase. It was then thought that Mr. George A. Schroter was on the point of putting the completing touch to the problem. Further unexpected delays, however, occurred. It is now stated on good authority that Mr. Schroter's engagement as consulting engineer having terminated by effluxion of time, Mr. Philip Argall has been appointed in his place. It is said the directors were influenced in tak-

ing this step by the desirability felt of their being in direct touch with a metallurgist of undoubted standing, having his headquarters at Denver, possessing also the necessary local expert knowledge of the special conditions of mining and milling at Cripple Creek.

Toronto, Canada.

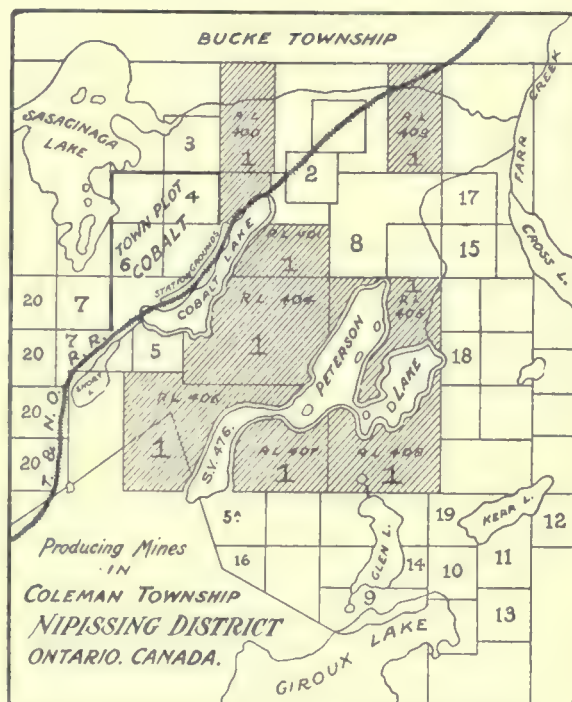

Nipissing and Its Title.—Conflicting Opinions.—Regulation of Joint-Stock Companies.—A Custom Smelter.—Mining Operations at the Cobalt Mines.—Wonderful Ore.—Chunks of Silver and Niccolite.—Supposed Gold Find.

The latest phase of the situation as regards Nipissing and the alleged flaw in the title, which was the cause assigned for the withdrawal of the Guggenheim interest, is the issue of a writ by John McKay, a Cobalt contractor, claiming 40 acres, part of which is now held by the Nipissing company, on the ground of priority of discovery and fraud on the part of the locators. The writ names as defendants the Nipissing Mining Co., Ltd., E. P. Earle, James B. O'Brien, Michael J. O'Brien, Thomas Herbert, Arthur Ferland, Severin Ferland, and Wm. C. Chambers. The area claimed includes 20 acres of the north end of the Nipissing property. The Nipissing interests and other mine owners affect to regard this action as the result of Guggenheim manipulation to bear out their course in throwing up their option, and speak of the supposed flaw in title as a rumor originating in New York. Now, whatever may be the case as to the motives inspiring the law proceedings, one fact is abundantly clear, namely, that the rumors as to the vulnerability of the Nipissing and other titles did not originate in New York. They date back to the early days of the camp. After claims had been located wholesale by 'snow-shoe prospectors,' it was again and again announced that many of them were likely to be disallowed on the ground of fraud, and the Nipissing was specified as being one, the title to which would be attacked. As a matter of fact, these anticipations were not realized. There was no general onslaught on shaky titles, and, possession being nine-tenths of the law, there is not likely to be any at this stage. Still it is easy to be seen how the revival of the question of title is at any time likely to have a disturbing effect on the market, and, until the law is changed so as to confirm the titles and remove all doubts, it must be reckoned with as a possible factor in stock manipulations.

The Provincial Government has drafted a bill to be submitted to the Legislature, making drastic changes in the law respecting joint-stock companies. It requires very full returns to be made at annual meetings, provides for the issue of share warrants by the delivery of which shares may be transferred, and renders directors liable for all statements in prospectuses, including those based on expert testimony. A fixed minimum share subscription is insisted upon prior to the allotment of share capital, in order to prevent flotations on inadequate capital.—The North American Cobalt Refining Co. has decided to erect a large smelter for the treatment of Cobalt ores. The company, the principal shareholders of which are mine owners, has been carrying on experiments for six months at a smelter erected at Hamilton, at a cost of \$35,000, and claims that they are able completely to separate the arsenic, cobalt, and other by-products from the silver. The plant to be erected will cost approximately \$200,000 and have a capacity of 500 tons per day. It has not yet been decided whether it will be placed at Hamilton or some other point.

At the Nipissing mine there are 200 men at work, operations being continued day and night. On veins 10, 19, 25, and 49, shaft-houses have been built and the shafts

will be put down 500 ft. At No. 10 a cross-cut will be run at the 100-ft. level to No. 26, which is about 50 ft. distant. The shafts at No. 10 and 27 are now down about 40 ft. and that at No. 19 has reached a depth of 70 ft. Vein No. 26 is being worked at the 55-ft. level, where 180 ft. of driving has been done. This vein is wholly in the Keewatin formation and has so far yielded ore worth \$300,000. No ore is now being taken from vein No. 49, known as the Bonanza vein, as a lower depth is to be reached before driving. Forty-five barrels of rich ore are awaiting shipment.—Preparations are being made for the installation of a stamp-mill at the McKinley-Darragh-Savage mine. A nugget of niccolite and silver was recently unearthed in the course of open-cut operations, that weighed 700 lb. and ran 2,000 oz. silver per ton. It was found on vein No. 1, which runs into the corner of Cobalt lake, owned by the company. The shaft on this vein is

19. Silver Leaf Mining Co.
20. Temiskaming & Hudson's Bay Co.

down 175 ft., and driving has been done at the 75-ft. level, and the vein exposed for 100 ft., presenting a width of 8-in. niccolite and silver, showing 2,500 oz. silver per ton. At the 150-ft. level there will be a cross-cut run to shaft No. 2, which is now down 83 ft. The latter shaft is sunk on the vein, which averages seven inches, and is rich in argentite and wire silver. This vein also runs into the lake. No. 3 shaft has been sunk 55 ft. and driving has been begun on the 59-ft. level. The vein is silver and niccolite, carrying about 1,200 oz. per ton in silver. The company has purchased from Allis-Chalmers-Bullock, Ltd., Montreal, a quantity of machinery including a cross-compound air and compound steam Ingersoll air-compressor, Ingersoll rock drills, two 80-h. p. boilers, a Lidgerwood standard hoisting engine, etc.

At the Red Rock, Joseph Harrass, the superintendent, an experienced Cornish miner, states that 17 veins have so far been traced and 3,000 ft. of stripping done, test shafts being sunk on all the veins. At No. 1 vein the shaft is down 40 ft. and some driving done. The surface width, varying from 4 to 12 in., was found to be well maintained as well as the quality of the ore. The vein

known as No. 1 Extension, which has been stripped for 300 ft., is much richer. It is two feet wide and heavily charged with native silver. A 40-ft. shaft has been sunk on it.—Extensive development work is going on at the Foster mine. Alexander W. Scott, late manager, has left the service of the company, which is looking for a man to take charge. Four shafts have been put down and stoping between two of them has been done to the extent of 110 ft. The installation of the extensive new plant is being rapidly proceeded with, and it is expected to be in operation by the new year.—A 400-lb. nugget was found on vein No. 1 of the Green-Meehan mine on the 8th inst., and another of 200-lb. weight this week.—The shaft of the Nancy Helen is down 80 ft. and a rich vein is being worked, a quantity of ore being ready for shipment.—A strike of gold in the Kinler shaft of the Temiskaming & Hudson Bay property was reported a few days ago. It is stated that assays showed \$151 per ton in gold and \$5 in silver in a vein six feet thick. The report has not been confirmed and experts are not disposed to attach much importance to it.

Prof. W. G. Miller, provincial geologist, received a telegram yesterday from E. T. Corkill, mining inspector in charge of the Government work on the Gillies timber limit, Cobalt camp, stating that in drifting on the 70-ft. level a large body of high-grade silver-cobalt ore had been uncovered. On the other vein which is being developed, a depth of 25 ft. has been reached and, though the ore is not so wide as on the first vein, it has been determined to let a contract for a shaft of considerable depth. Prof. Miller left yesterday for the mine to investigate and report on the discovery.

Cobalt, Ontario.

Discoveries in the Red Rock.—Story of Varying Fortune.—A Railroad Track Rich in Ore.—The Right of Way Co.—Nipissing and the Guggenheims.—Gossip of the Camp.

One of the richest of the recent finds has been made at the Red Rock where a vein has been exposed for 300 ft. with a width at the surface of two feet and disclosing a streak of solid argentite and native silver two inches wide. A 40-ft. shaft has been sunk on it at one end near the Green-Meehan line and the richness and width have been steadily maintained. This vein has been called Extension No. 1. It runs parallel to the vein called No. 1 and, therefore, it is not obvious why they call it an extension. The Red Rock consists of 40 acres, being the northwest quarter of the south half of Lot 14 in the First Concession of Bucke, and adjoins the Green-Meehan. Coleman and Bucke townships adjoin. The Red Rock was formerly owned by McMartin, Timmins, and Dunlop who are well known as the owners of the celebrated LaRose mine. They formed a company with a capitalization of \$1,000,000 and put about 150,000 shares on the market at a par value of one dollar. A good vein was known to have been located and the stock was largely subscribed. Then a shaft was started and it is said that in sinking it they lost the vein or it petered out. Despite the large holdings of the public, the promoters got disheartened and for months work was practically abandoned. Some outsiders with faith in the property had it carefully but quietly examined, and as a result they secured an option on the remaining 792,000 odd shares at a price of less than 25 cents per share. In the meantime an enormously rich vein had been found on the Green-Meehan, which consists of the 40 acres directly to the north, and the vendors sought to evade the sale, but the deal was closed. R. R. Gamey, F. B. Chapin, president of the McKinley-

Darragh-Savage mines, and Geo. E. Bristol were among the purchasers, and they sold within a few days to a New York and Pittsburg syndicate, of which Quincy Ward Boese is the controlling spirit. The purchase price has not been made public, but within a few days of the second sale the rich find was made that has been described. The vein had been known for some months, but it had not been sufficiently stripped until recently to show the rich outcrop.

The big Green-Meehan vein extends into the Red Rock, but just at the dividing line between the properties it divides into two branches of two feet each. One of them has been stripped for 200 ft., and carries six inches of very rich ore. It is well defined and promising; a shaft has been sunk on it and, by cross-cutting, the other branch (known as No. 16) and a third vein, called No. 15, will be worked. Vein No. 15 was one of the veins first found. It consists of calcite with cobalt and some silver. At the Red Rock one car of high-grade ore and two cars of low-grade stuff are ready for shipment. Seventeen veins have been identified, and as only half the property has been prospected, the present outlook in that part of the township is most promising. Joseph Harrass is the superintendent; he is a well-known Cornish miner who has worked in Ontario in the Sudbury and Kingston districts; E. C. Kingswell, of Haileybury, is consulting engineer.

A railroad that has its own mines and that takes out ore running 6,000 oz. silver by the side of the track appears to belong to the pages of romance, but such is actually the case at Cobalt, where the company known as the Right-of-Way Mining Co. is working three miles of the track allowance. Cobalt lake lies in about the middle and the track runs along it for about a mile, so that while the company has from mile-post 101 to 105 it has only about 1½ acres lying between the O'Brien mine and the lake. At a point on the track opposite the boarding house of the La Rose mine they struck the rich Timmins vein and it is thought by mining men in the camp that this vein extends right down to the lake. The vein has been uncovered for about 40 ft. and has a width of eight inches of silver and niccolite, which runs as high as any ore in the district.

The government railway has given the Right-of-Way Mining Co. a 999 year lease of these three miles in return for \$50,000 in cash and a flat royalty on all ore mined. The company is capitalized at \$500,000; the shares have a par value of one dollar and have sold as high as \$12. T. Beaumont, an Ottawa lawyer, is the president; G. O. McMurtry, is the superintendent, he is a Canadian, well known at Rossland and Nelson, B. C.

The action of the Guggenheims in refusing to carry out their agreement for the purchase of a block of Nipissing stock is looked upon here as an effort on their part to cause a slump by taking advantage of which they could secure the same amount of stock at a much lower rate than they were agreeing to pay. Their option called for \$25 per share. The Canadian holders of the stock were not frightened and kept a tight grip on their holdings. The attempt to cast discredit on Cobalt titles has caused indignation in this country and the Government of the Province through its Premier, has declared that the title to the Nipissing property was not questioned. It is known that the Guggenheim agents have been in camp for months and that they have secured options on a great many properties. It has also been stated that these same people contemplated the erection of a smelter. The outcome will undoubtedly be the erection of a Government smelter for the treatment of the copper, silver, and nickel ores of the region now known as New Ontario.

Mining Summary.

ALASKA.

The official records at Dawson show that the Klondike gold output for this year was slightly over \$5,600,000. This includes all the gold-bearing territory within 50 miles of Dawson, and the year's collection of royalties is based on these figures. Ten full mining seasons have passed since the discovery of the Klondike, the total output to date from this district amounting to \$112,000,000. Large dredges are now working on Bonanza and other creeks, with many more to be installed next season.

ARIZONA.

COCHISE COUNTY.

The 1,000-ft. level which the Tombstone Consolidated Co. has been striving to reach for the past four years has been gained, after the expenditure of several million dollars and the handling of an average of 4,000,000 gal. of water every 24 hours during that period. A large station will be cut out at this level and a sump 35 ft. deep will be sunk to handle the water. A set of mammoth pumps will be erected at the station similar to those now in use at the 600 and 700-ft. levels. The underground workings will be pushed into the old Grand Central and Contention properties to tap the ore-bodies known to exist below water-level.—Work is progressing rapidly at the Silver Thread, the 600-ft. level having been gained. The winze had reached a depth of 135 ft. from the 500-ft. level when copper was struck, and water prevented further working at the time. At the mill, 40 stamps are kept at work continuously, and last week a shipment of concentrate valued at \$25,000 was made; a regular clean-up of bullion takes place every two weeks.

An entirely new body of high-grade sulphide ore has been found in the P & D ground, Quadrangle district, near Bisbee. The strike was made in a drift that is being run from the 1,100-ft. level of the Lake Superior & Pittsburgh shafts. Samples have been taken along the exposed vein for assay. Lack of fuel has crippled the pumping at the Briggs shaft belonging to this company, and sinking has been stopped until the fuel famine is mitigated.—A strike has also been made at the Junction mine at the 1,000-ft. level, in a drift running westerly toward the Gardner and Sacramento ground of the Copper Queen Co. Returns from assays are said to be very high, but exact figures have not so far been made public.

PINAL COUNTY.

(Special Correspondence).—The Big Lead Milling & Smelting Co.'s concentrating plant at Kelvin, with a capacity of 50 tons per day, is finished and ready for work, and the wheels of the new machinery are to begin grinding out high-grade concentrate that runs from 35 to 40% copper in a few days. W. E. Sharps, of Philadelphia, president of the Big Lead Mining & Smelting Co., Calumet Copper Mining Co., and Kelvin Reduction Co., whose properties are located six miles north of Kelvin, on Mineral creek, is on the ground making an inspection of the prosperous property of which he is the official head. Under the able supervision of Mr. Tuitchell, superintendent of both the Big Lead and Calumet companies, and of R. G. Mead, superintendent of the Kelvin Reduction Co., all obstacles have been met and the flattering predictions made two years ago regarding these properties have been fulfilled. Mr. Sharps has been greatly assisted in this great undertaking by Mr. Tuitchell, for under his supervision at the mines the ore is mined in an up-to-date fashion. Not a dollar is expended unless absolutely necessary; no debts are incurred unless ample funds are on hand to meet them; the company has never missed a pay-day; its credit is the best and its standing excellent. The Calumet Copper Mining Co. is shipping large quantities of copper ore to the Humboldt smelter and the management is well satisfied with the output of the mine. In connection with the Calumet it is said that since Mr. Sharps arrived, he has had two flattering cash offers for the property and he has unhesitatingly refused them. Owing to the large number of claims in the district carrying sulphide ore, it is intended to increase the capacity of the Kelvin Reduction Co.'s plant, and in addition to the leaching of the copper,

which is now progressing favorably, concentrating machinery will be added and the ore from the mines of its own and also custom ore from various claims adjacent thereto will be worked, much to the advantage of both the producer and operator.

Phoenix, Dec. 15.

CALIFORNIA.

INYO COUNTY.

A syndicate of capitalists with Dr. W. J. Nelson of Los Angeles at their head, is about to begin the development of the S. P. Roberts group of mines recently acquired in the Pine Mountain district. Heavy snow-storms will prevent much work being done till the spring, when the present adits will be continued so as to test the lodes that outcrop above. Fourteen mines are included in the deal; they are situated on Index hill and are the heaviest lead-bearing deposits in the district, carrying also some gold and silver. The mineralized belt, half a mile wide, is known to extend at least four miles north and south. The country rock is a brown slate, containing lime. The ore at 200 ft. runs from \$10 to \$12 in gold, while kidneys of high-grade galena were frequently encountered in the older workings. Water and wood are plentiful in the vicinity.—The Black Canyon Co. has driven two tunnels each 90 ft. long into the orebody exposed in Black cañon, 10 miles from Bishop. The ore encountered in both cases is of an average value of \$20 per ton.

MONO COUNTY.

A number of companies were organized last week to develop mines in the Masonic district. A million-dollar corporation, the Masonic Investment Co., organized at Carson, Nev., has obtained control of a number of claims, including the Oro Grande, Golden Mammoth, South Side, and Emporium. The Caliveda M. & M. Co., another Nevada corporation, has taken over the Wednesday and Wednesday Fraction, and has also purchased the Golden Reef and Golden Crown from Van Sickle, Smith, and Simmons. The Masonic M. Co. is doing extensive work on the True Friend group, and is reported to have uncovered a fine orebody.

NEVADA COUNTY.

The Boss mine, between Sweetland and North San Juan, a low-grade proposition with an immense orebody, is to be worked on an extensive scale by C. L. Crane, E. H. Benjamin, John Collier, and associates. A crew of men will be put to work at once, a hoisting plant erected, and the big lode given a thorough test. In the spring a mill and cyanide plant will be built.

The California mine on Deadman's Flat, which was shut down about 12 years ago owing to litigation, is being unwatered preparatory to the resumption of work upon an extensive scale. Electric power is now available, and the pumps will be kept running day and night. The hoist has been found to be in good condition, and, with the unwatering of the shaft, active mining will begin. The mine paid handsomely in the past, and it is known that an extensive vein of good quartz lies at the bottom of the shaft.

SHASTA COUNTY.

After years of litigation the Harrison Gulch townsite case has been decided by the Commissioner-General of the Land Office, who rejects the application of the townsite company for a patent. The owners of the Bonanza claim, who contested the application, have won the case. The decision involves the entire town of Harrison Gulch, which is thickly settled.

TUOLUMNE COUNTY.

Electric power and water is again obtainable, and as a consequence the usual activity in mining is being resumed. — Conlin Bros. have purchased a 40-h.p. compressor for the Experimental mine, near Columbia, and intend to begin at once driving a 1,000-ft. adit at that property.—Operations have been temporarily suspended at the Lone Star mine, situated a few miles north of Confidence, owing to the severity of the weather. Ten men have been employed at this property.—The Omega and Crystalline mines will resume operations about January 1, provided fuel-oil arrives by that time. W. C. Ayers, the superintendent, has gone to Tonopah for a few weeks. It is reported that he will assume charge of properties there also.—It is expected

that the work of unwatering the Mazeppa mine will be completed within 30 days, when active underground work will be commenced. The shaft is 900 ft. deep, and there are several drifts above the 500-ft. level. It is the intention to start two new drifts, one at the 700 and another at the 800 level.—Some high-grade ore has been uncovered at the 150-ft. level of the Imperial mine, situated near Jacksonville. The property is under the superintendency of Chas. Fitzgerald, who is pushing development work along as fast as possible. Driving is in progress on the level mentioned, and soon sinking will be resumed. The rich shoot of ore recently uncovered is from 10 to 30 ft. wide.

Tuolumne, Dec. 18.

YUBA COUNTY.

The majority of the stock of the Marysville Gold Dredging Co., comprising the interests of Eugene De Sabla, John Martin, W. P. Hammond and others, has been sold to the New England Exploration Co., of Boston, of which R. E. Cranston, of Sacramento, is Pacific Coast manager. The consideration is said to be \$8,000. The company owns 1,300 acres of mining ground adjoining the Yuba Consolidated goldfields on the Yuba river ten miles east of Marysville, and has two large dredges operating and others building.

COLORADO.

CLEAR CREEK COUNTY.

A vein a foot wide of smelting ore assaying from 150 to 300 oz. silver per ton has been uncovered at the Little Emma mine, on Democrat Mtn. The discovery was made in running a cross-cut from the old workings, the ore being similar in character to that mined a number of years ago when the property was being developed by P. J. McNulty, and a production in excess of \$350,000 extracted. The present owner, Patrick Walsh, is now opening up the new ground preparatory to stoping, and the first shipment of high-grade ore is to be made in a few days.—The Mammoth property, located on the opposite side of the gulch from the Terrible and other famous mines above Silver Plume, has been secured under option by Daniel Williams, representing Denver capital. Work will be started forthwith. In the Mammoth there are large bodies of lead and zinc ore that could be handled at a good profit with proper milling facilities. The new operators will construct an aerial tramway connecting the dumps of the mine with the wagon-road, from whence the product can be handled in an economical manner. A milling plant near Lawson has been secured, and the low-grade ores will be shipped there for concentration. This mine was idle for a number of years until about 18 months ago, when it passed under bond and lease to Dennis Gibbons, of Denver.—A party of Denver and Eastern capitalists has purchased the lease held by William Jewell upon the dumps of the upper Mendota workings. A concentrating mill will shortly be constructed near the old Brownville schoolhouse, and the preliminary work is already well in hand.—An important strike has been made at the old Lucky Hesperus, at one time the richest mine of the Democrat Mtn. district. A solid body of smelting ore was uncovered last week, the vein measuring over 12 in. thick, and assaying 300 oz. per ton silver. The ore-shoot, which was lost a number of years ago, is believed to have been found by Chas. Carlson, who holds a lease upon the property, and as soon as the ground has been opened up for the required distance stoping will be carried forward. The discovery was made while running a cross-cut under the old workings, and a large area of virgin ground has now been opened up for further exploration.

The Main Gulch Co. has declared a dividend, after less than eight months of operating. Since taking hold of the property the management has sunk the shaft to a depth of over 100 ft., and about 1,100 ft. of driving along the vein has been accomplished. On the third level the top of what is known to be a large orebody has been passed through for a length of over 150 ft. The shaft is being put down in order to intersect this orebody at greater depth.

TELLER COUNTY.

The Union Leasing Co. has taken up the lease on the tenth level of the C. O. D. mine, near Cripple Creek, for-

merly operated by Hayden & Gallagher, and recently forfeited by them. The Leasing Company will explore at depth for the Gold Coin vein, which is known to enter the C. O. D. property. On the fourth level of this mine, Tillery & Co. will resume cross-cutting shortly.—The Beacon Hill Development Co., operating on the 600-ft. level of the Gold Dollar mine on Beacon hill, last week shipped four cars of ore, two of which are expected to give from five to seven ounces in gold per ton.

IDAHO.

SHOSHONE COUNTY.

The International Mines, Ltd., developing 11 full and four fractions near Burke, will award contracts for 400 ft. of additional adit, which is expected to cut the vein in a few days. This will bring the face of the adit in 450 ft., with a vertical depth of 175 ft. Announcement was made that the Federal Mining & Smelting Co. has acquired the property.—Half a carload of ore has been shipped from the Pilot mine near Murray, for treatment at Denver, Colo. The Pilot is the property on which the sensational gold strike was made last summer. The group had been bonded to the Day brothers for \$200,000 and a payment of \$20,000 made. The Day brothers did a considerable amount of development on the property but did not have sufficient time to satisfy themselves with regard to the extent of the strike. When the second payment became due, they applied to the owners, Frank Frohling, John Docktor, and L. Prager for an extension of time. This was refused and the property reverted to the original owners, who are working it.—The vein on the Mineral Farm group, near Mullan, is, from surface indications, 100 to 300 ft. wide. The lower adit has been in tale for nearly 400 ft., but recently at a point 700 ft. from the portal, the vein matter became sufficiently solid to hold without timbering.—William A. Nichols of Spokane and Kratzer & McKinnis of Wallace, have secured the control of the National Mining Co., owning a group of six claims on Snowstorm mountain, near Mullan. The claims are just west of the Lucky Calumet and join the Independent and the Copper King on the south. The company is capitalized for \$1,250,000.

Six feet of copper ore is the strike on the 250-ft. level of the Reindeer mine near Mullan. It is the intention of the company to sink 100 ft. on the orebody. Enough ore is blocked out to make five or six shipments.

NEVADA.

LINCOLN COUNTY.

(Special Correspondence).—Among the later companies to develop properties in the Searchlight district, the New York-Searchlight may be mentioned. Financed by a syndicate of New York capitalists, the management are installing the first diamond drill for use in the district. The property owned by this company consists of the Waterspout, Orlando, Eclipse, Daylight, and Starlight lode mining claims, situate north of the Duplex and Quartette mines and due east of the Santa Fe. The shaft on the Waterspout claim was sunk for the purpose of striking water for domestic purposes. Water was encountered at a depth of 145 ft., but was unfit for such use owing to the copper taint. Prospecting at this depth revealed the existence of three well-defined veins carrying gold and copper values. The shaft is now down 240 ft. all in ore. Values on this property run from \$3.20 to \$86 in gold with a small percentage of copper.—Crescent lies on the western slope of the Crescent hills, which divides the Searchlight valley from the Ivanpaugh valley. The Crescent district is one of the oldest mining sections in the State of Nevada. Mexicans worked the Zatche mine, now known as the Old Mexican, and the gold and silver production from 1863 to 1878 amounted to over \$500,000, which was transplanted on burros to Good Springs, where it was arastred and melted into bullion bars. In July, 1878, a band of Mormons raided the burro wagon, killing most of the leaders, after which the mining in this district was suspended until the spring of 1904, when a party of Eastern mining men re-located the mine, and within six months 300 claims had been recorded in the Crescent district. At the present time there are 23

companies actively operating and upward of 25 owners developing. The district has all the characteristics of the Searchlight camp, especially the immense veins that trend north and south. Within one year over two millions of dollars worth of ore was blocked out on two properties and surface showings approach those figures. The following are among the developing mines: The Nippeno, which is down 325 ft., having immense bodies of high-grade ore in sight; the Lucky Dutchman with a depth attained of 350 ft., showing a heavy ore reserve. The Tiger mine is sinking a vertical shaft on the vein that traverses the entire length of three claims, a cross-cut showing 178 ft. of ore averaging better than \$8 in gold. This is one of the big bonanzas of the district.

The Barnwell & Searchlight railway is building a standard guage road from Manvel on the Santa Fe system to Searchlight, a distance of 26 miles. The road is expected to be in operation about January 1, 1907. The graders have the road to within three miles of Searchlight, and the track is completed for a distance of fourteen miles. The arrival of the railroad will be the cause of much rejoicing among the mine owners of El Dorado cañon, where many thousands of tons of base ores that are now blocked out can be transported to the smelters at Needles and made to pay a good profit. Heretofore, owing to the excessive freight charges, these properties shipped only the high-grade output.—The Salt Lake route has a station at Nipton, 25 miles west of Searchlight and passengers are carried in six-horse Concord stages operated by the Nevada Transportation Co. The road is kept in good condition all the year round, and good time is made.

Searchlight, Dec. 10.

WHITE PINE COUNTY.

The Copper Basin Syndicate has purchased a group of rich copper claims on Bald Mtn., in the Ely district. The property carries gold, silver, and copper, and the consideration is said to be \$300,000, a cash payment having been made of \$30,000. There is a large body of ore now in sight, which has been sampled and found to give an average assay of 5% copper, \$10 in gold, and \$10 in silver. The syndicate now has a force of thirty men at work, which will be increased in the spring, when a large furnace will be erected.

NEW MEXICO.

SOCORRO COUNTY.

The Graphic mine in the Magdalena district is now employing 60 men and the force is to be increased in the near future. This claim, one of the abandoned mines of New Mexico, was bought by an Eastern company for the zinc, and has paid for itself a couple of times since it was purchased by the present corporation. A large amount of development work has been done, and the great vein of copper formerly worked has been uncovered at a greater depth in the new adit.—Another of the worked-out mines picked up by Eastern capital is the Kelly claim, now owned by the Tri-Bullion company, which has already paid back the purchasers the price of the property. A contract has been recently closed for an equipment of hoists, compressor pumps, and electrical machines. The hoisting plant will handle 500 tons per day from a depth of 1,000 ft., the compressor operating 15 Ingersoll drills. A complete reduction plant is to be installed, consisting of a 300-ton zinc plant and a 350-ton concentrating plant with two furnaces, for silver-lead and copper ores respectively.

SANTA FE COUNTY.

The San Pedro copper mine, situated 21 miles south of Santa Fe, now owned by the Santa Fe Gold & Copper Co., of New York, is to start work again, giving employment to a large number of miners. The company is virtually a reorganization of the old San Pedro Copper Co., that became bankrupt 15 years ago. The property includes the San Pedro and Cañon el Agua grant, comprising 50,000 acres of land, a large proportion of which is mineral, including good coal-lands. The copper vein being worked is a blanket vein of sulphide ore 175 ft. thick, dipping at an angle of 15°. The ore is low-grade, that mined and smelted years ago giv-

ing 4.75% copper, \$1.50 silver, and \$1.50 gold per ton. A reserve of 30,000 tons of ore has been blocked out, and the workings are in good shape in spite of the long period of idleness. The ore is silicious, requiring heavy lime and iron fluxes.

OREGON.

BAKER COUNTY.

(Special Correspondence).—About eight years ago a small organization of eight traveling men started what is now the Commercial Mining Co., of Portland. Their purpose was to develop a prospect on Burnt river, about 30 miles southeast of this city. Work to that end has been going on constantly, and this year the prospect developed into a mine from which the output is now \$1,000 per day in free gold. Fourteen triple-discharge stamps are in use.—The Colts mine, situated a short distance from the property of the Commercial Co., is also on the producing list, with a 10-stamp mill that is kept busy; 35 men are employed.—The Tetro and Kidd property, recently purchased by J. W. Messner from Regan & McCord, is in the same district and is operating a 5-stamp mill with good results.—The Gold Coin is distinguished for the exceptional width of its ore-body. The vein is a conglomerate about 60 ft. wide, that is said to average \$9 per ton in free gold. A 10-stamp mill was erected, but on the eve of starting, it was destroyed by fire. The plant is to be rebuilt and 10 more stamps will be added.—Col. James Panting, owner and manager of the Gold Hill mine, is making some improvements with a view to active production.—Burnt river has long been noted for its placer gold and some of the earliest diggings in eastern Oregon were worked in this district. Only the rich ground in the channel, however, attracted the early miners. Recently J. F. Batchelor bonded a number of ranches lying along Burnt river, among them the Thompson & Swasey ranch, the Ellis ranch, the Shook ranch, and the Sissley ranch. His purpose is to put dredges on these farms as soon as spring opens.—On the Powder river side of Lookout Mtn., about 12 miles from the Conner Creek mine, the most notable property is that of Timber Canyon. About 1,000 ft. of work has been done underground and an ore-shoot 150 ft. long has been developed at a depth of 120 ft. The vein is four feet between walls and the ore will average \$15 per ton in gold. A 5-stamp mill is to be erected.—Across Powder river, on the Copper Belt, it is stated that, at the Indiana mine, a cross-cut on the 300-ft. level has penetrated 40 ft. of ore that will average \$50 per ton in copper, gold, and silver. On the opposite side of the Burkemont, James A. Howard and associates recently acquired control of a property on this belt, and underneath a gossan capping have uncovered a big lode of copper ore of a promising character.—The North American property, which occupies a central position on this belt, and which for the last year has been in process of development is on the eve of changing hands. A bond for \$1,500,000 has been executed by the company to New York capitalists, on an option extending to January 1.

Baker City, Dec. 15.

JOSEPHINE COUNTY.

Development work is being pushed in the Briggs mine, at the head of Sucker creek, near Grants Pass, and up to date aggregates about 1,200 ft. of sinking and driving. Three separate lodes are exposed, running nearly parallel. The first of these is the one on which the rich strike was made in 1904, and is about eight inches wide, giving phenomenal returns in places. The second vein is large, about 20 ft. wide, giving an average assay of \$8 per ton in free gold, besides concentrate. The third vein was discovered in cross-cutting what was thought to be the lode-walls. This cut has been driven 70 ft. and is still in ore, assaying about \$20 per ton, mostly in sulphides. A projected wagon-road will facilitate development and equipment of this property, as the remoteness of the place and difficulty of transportation impede progress. In winter it is impractical under present conditions to bring in supplies for more than a small force of men. With the completion of the road, machinery will be installed for the erection of a stamp-mill of large capacity.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE underground workings on the Comstock lode at Virginia City, Nevada, aggregate more than a total length of five hundred miles.

It now appears probable that one gram of radium diminishes in weight about one-half milligram per annum; at this rate of dissolution a gram would last about 2,000 years.

THE reverberatory copper furnace, with its neutral atmosphere, produces a richer matte from the same ore-charge than a blast-furnace which has a powerfully reducing atmosphere.

POWER of water for removing gravel, etc., is in proportion to the square of its velocity and the square of its velocity is proportionate to the grade if the hydraulic radius is the same in each case.

TELLURIUM, which occurs native at the Good Hope mine, in Gunnison county, Colorado, is a silver-white metal, like tin, but it has a marked crystalline structure. It has a very limited use in the arts.

THREE KINDS of material are considered practicable in building smelter stacks, namely, reinforced concrete, steel lined with brick, and radial brick. In the last the sides of the bricks are laid in line with the radius of the circular cross-section of the stack.

THE separation of matte and slag depends mainly upon the difference in their specific weight. Hence, it is difficult to keep the copper low when basic, ferruginous slags are produced, while an earthy or silicious slag is usually very free from grains of matte.

A STRIKING EXAMPLE of a rise in mining shares is afforded by the case of the Sierra Nevada mine on the Comstock lode which, in 1882, rose during eight months from a price of 50 cents per share to a maximum of \$275—so that an investment of \$1,000 would have brought \$550,000 in less than one year.

THE Main Reef series of gold-bearing beds of conglomerate on the Rand has been traced for a distance of about fifty miles. Claims have been taken up for a width of 2 to 3 miles. Litigation over territory is unknown because the law of the apex is not in use; acreage, not apex, gives title to the ore.

CORUNDUM AND THE SAPPHIRE are essentially identical in composition; they are alumina, the oxide of aluminum. The sapphire is the transparent form of this substance, corundum is the opaque variety. Emery is a mechanical admixture of corundum and magnetite. It is the presence of corundum in the emery which gives it value as an abrasive.

ASSAYS are not commonly made at the gold mines of the southern Appalachians. Usually the value of the ore is measured only by the recovery on the plates and by chlorination. As ore from several orebodies is run through the mills promiscuously, it is difficult to determine the value of any specified lot. The system appears incredible to Western operators.

THERE are many ways of working coal nowadays, and, in order to come to a decision as to the best mode of

working, an engineer must know (1) quality and nature of roof and pavement; (2) quality and thickness of coal; (3) quality and quantity of ribs of refuse in seam; (4) inclination; (5) whether gassy or not; (6) depth from surface; (7) nature of surface as regards property, rivers, reservoirs, etc.; (8) whether the field is faulty or not.

THE paper of the late Professor Curie on 'The Effect of Temperature on the Magnetic Properties of Bodies' led to the discovery of the law that for feebly magnetic substances the coefficient of magnetism varies inversely as the absolute temperature. He also pointed out that the magnetization of diamagnetic substances appeared to be independent of the temperature and physical state, indicating diamagnetism as an *atomic* property.

THE electrolytic refining of copper was one of the great discoveries of the age, for it became the foundation of modern electrical engineering. Without copper of high conductivity, the dynamo, the telephone, and the transmission of power would not exist in their present forms. To Edward Balbach and his assistant, F. A. Thum, who originated the electrolytic refining of copper in 1883, a great debt is owing from the industrial world.

LITHIUM is used in the manufacture of lithium carbonate; this is the basis of the lithia waters, which are regarded as having good medicinal effects. Lithium, in the form of the oxide, lithia, is derived from lepidolite and spodumene. The former occurs in large deposits at Pala, San Diego county, California, and the latter is chiefly obtained from the Etta group of mines, in the Black Hills of South Dakota.

ALUMINUM PAPER is now manufactured in Germany, and recommended as a substitute for tin-foil. The paper is used as a sort of artificial parchment obtained through the action of sulphuric acid upon ordinary paper. The sheets are spread out and covered upon one side with a thin coating of a solution of rosin in alcohol or ether. Evaporation is hastened by means of a current of air, and the paper is then warmed until the rosin has again become soft. Powdered aluminum is then sprinkled upon it, and the paper subjected to strong pressure.

LOSSES IN CONCENTRATION.—The following general rules are useful in deciding as to conditions favorable to small losses:

(1) If the ore is fairly hard and breaks without the formation of dust.

(2) If the valuable mineral of the ore is heavy and easily detachable from a lighter gangue.

(3) If the ore can be sorted by hand-picking so that but little is sent to the mill for concentration.

On the other hand losses will be high when:

(1) The mineral and gangue are finely knit (composed of fine grains uniformly aggregated).

(2) The ore is so friable as to disintegrate under the action of water treatment.

(3) Mineral and gangue are nearly of the same density.

(4) The mineral is scattered through a hard gangue so that it gets ground up more than the gangue, especially if finely ground.

(5) The ore, as in the case of certain copper carbonates, is high grade.

In general ores containing native metal or sulphides are better suited to concentration than the oxidized or carbonate ores. As regards physical character, the coarsely knit ores work the best. The eye alone is not a sufficient guide, and nothing but a practical test will determine whether or not an ore can be economically concentrated.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Cyanide Practice at Kalgoorlie.

The Editor:

Sir—I considered it a fortunate moment when a copy of your issue of July 28 came into my hands, and enabled me to read with interest and also a little amusement an article by Mr. Alfred James on 'Crushing and Grinding Practice at Kalgoorlie.' As you mention that any reply to Mr. James' criticisms will be given a courteous hearing, I trust that it will be so in this instance.

With the exception of a few remarks in the first part of the article in question, there is little to disagree with, but it is when Mr. James leaves general views, and gets down on to more detailed work, that he appears to lose his balance, especially in regard to his criticisms on the tests made at the Ivanhoe mine, at Kalgoorlie, between grinding pans and tube-mills. Although I left the service of that company in March last, it is natural that an attack (like the one now under review) on those experiments, which were carried out by Mr. R. B. Nicolson and myself, should evoke a reply.

Taking that part of Mr. James' paper which relates to pans against tube-mills, he opens with a reference to a mysterious mine at Kalgoorlie, that is practising bromo-cyanide treatment without using bromo-cyanide methods, and in consequence the residues of this mine are reputed to be worth $2\frac{1}{2}$ dwt. per ton. With the exception of the loss in residues, I have a shrewd suspicion what the name of the mine is, but would certainly advise Mr. James to call at headquarters, and get correct figures for the past few months, which are—I dare to say—considerably under his estimate.

The question of extraction was entirely left out of the Ivanhoe tests. The point to be proved was, which was the superior grinder, a pan or a tube-mill. Personally, I think very little difference would be found in the extraction obtained from the slime made by either of these two machines.

I am glad to see Mr. James regrets that names of such high standing should have been tacked on to tests so badly carried out as were those at the Ivanhoe. While appreciating the compliment in the first part of this sentence, I would also apply the same remarks to Mr. James and his article. This same gentleman, by a wonderful though erroneous deduction, then discovers that as the Ivanhoe tube-mill worked on alternate days, the flints were coated with slime at the start of each daily test! For Mr. James' benefit alone, I would inform him that at the end of a day's run of the tube-mill, the feed was shut off and clean water passed through for some time before the mill itself was stopped, and on re-starting for another day's run the mill was allowed to work for some time until its full load was reached before samples of any kind were taken. Setting aside this precaution, the fate of any slime left inside a tube-mill revolving at 32 revolutions per minute can be imagined.

Mr. James now comments somewhat sarcastically on the large amount of 'slime' (?) (-150 mesh) which is allowed to return to choke the tube-mill instead of being got rid of at once, and shows that the Ivanhoe mill had more slime returned than was its daily output of this product. The statement made in the Ivanhoe report that the tube-mill became choked, has been taken perhaps in too literal a sense. It is obvious that as long as the inlet and outlet of a tube-mill is large enough, practically any tonnage of sand can be rushed through. What happens in a case of this kind is that the various spitzkasten

used for separating the resultant slime and feeding the mill are gradually choked by the accumulation of fine sand returned for re-grinding, the effect of the tube-mill having more original feed than it can cope with, or, in other words, the mill may be said to be 'overloaded.' This is what happened during the Ivanhoe experiments. The tube-mill did not exactly choke, but the various spitzkasten employed did, and after every expedient failed the fine sand was only prevented from gradually gaining on the mill by reducing the amount of original feed. As there is a certain time at which a tube-mill must become overloaded, that particular point was naturally presumed to have been reached. The same remarks also can be applied to the grinding pans.

At this point it may be as well to get an idea of what Mr. James does consider good work by a tube-mill, and I have gone to some trouble in turning up a few statements made by him during the last few years, and in one of them in *The Engineering & Mining Journal* of January, 1905, I notice he makes the following remarks:

"I ask why is it that the Hannan's Star mill, the first one laid down, should be still doing the best work, while the Ivanhoe mill has been thrown out?" And further on we have: "The longest and oldest mills, those at Hannan's Star, and the old Brownhill exhibit the best results, etc."

Turning now to the *Journal of the Chamber of Mines* of Western Australia of March, 1904, we see some working results of this same Hannan's Star mill, which Mr. James appears to never tire in quoting. A glance at this latter paper reveals, in the light of present remarks, some astonishing figures, and I shall trespass a little on your space to reproduce them alongside those of the Ivanhoe. Before giving these it must be remembered that the Hannan's Star tube-mill was 16 ft. long, taking 30 h.p., and was reducing 38 tons of sand per day to a slime of -150, while the Ivanhoe mill was 13 ft. long, requiring 20 h.p. and bringing 19.5 tons of sand to a slime—also of minus 150. It may be added that of the original feed of 38 tons sent to the former mill, 20.5% remained on 40 mesh, while of the 19.5 tons sent to the Ivanhoe tube, 51% stayed above 40 mesh, or, in other words, the original feed to the Ivanhoe mill was $2\frac{1}{2}$ times as coarse as that sent to Hannan's Star. As it was demonstrated, in tests carried out at the former mine, that coarse sand had a bad effect on tube-mill work, this fact, taking the size of the two tube-mills into account, explains most of the difference in output.

As 'slime' (?) in the return feed is the product that worries Mr. James so much, I give below the grading from the two tube-mills:

Hannan's Star mill (16 ft.) 268 tons per day, being original feed and sand returned for re- grinding.			Ivanhoe tube-mill (13 ft.) 142 tons per day, being original feed and sand returned for re- grinding.		
	%	Tons.		%	Tons.
On 40 mesh	4.5	12.06		11.40	16.19
" 60 "	9.5	25.46		14.98	21.27
" 100 "	19.9	53.33		36.94	52.46
" 150 "	19.0	50.92		17.77	25.23
Through 150 "	47.1	126.22		18.91	26.85

A glance at the above figures shows that the Hannan's Star mill with an original output of 38 tons of -150 mesh slime per day contained in its return feed no less than 47%, or 126 tons of this same objectionable product, against the Ivanhoe mill with an original output of 19.5 tons, containing only 18.91%, or 26.77 tons. In other words, we have the extraordinary position of a man who for the last few years has been holding the Hannan's Star tube-mill up to the admiration of the mining world, executing a complete somersault, and condemning the tube-mill practice on a neighboring mine, when on his own showing this latter mill is doing far better work, espe-

cially as far as clean separation goes, than the one he is so proud of. It is unfortunate that Mr. James has allowed personal feelings to obscure his judgment on this occasion, and if he now puts the Hannan's Star mill figures in the place of the Ivanhoe, it is evident in what an unfortunate position he has placed himself.

As it is hardly necessary to comment any further on this, we will now go on to another paragraph in the paper under review where complaint is made that the pans—especially the first one—had an undue advantage over the tube-mill in matter of getting rid of finished product. Surely Mr. James does not condemn the practice of running the original or coarse feed into one pan and the return fine feed into a second to be slimed. This is one of the advantages of pans over tube-mills, as in the case of the latter one machine has to both reduce coarse sand and do the sliming as well. However, if Mr. James had looked at the feed entering the second or finishing pan he would see that out of a daily tonnage of 74.6 tons returned to this pan no less than 24.5 tons passed 150 mesh (being nine tons more than its actual output of this product), or, in other words, this pan had practically the same quality of feed as the tube-mill, so that both were laboring under the same disadvantage. It may be consoling to the gentleman in question that all tube-mills and pans grinding to a slime exhibit the characteristic of having more -150 'slime' (?) returned to them than is their actual output of this product, and it is, I should say, the result of not having a proper definition of what constitutes slime, and a better plan for separation of the same. Numerous attempts have been made of late to define what slime is, but so far the results have not been satisfactory. The common and practical definition at Kalgoorlie is: All that product which passes a screen having 150 holes per linear inch. This, however, is far from satisfactory, for anyone conversant with grinding practice knows how large is the quantity of very fine sand that will pass a 150 mesh readily, but is yet heavy enough to sink in a spitzkasten, and be returned to the tube-mill or pans again and again. Recognizing these difficulties, it was stated at the outset of the Ivanhoe experiments that all that product which passed a 150 mesh would be called 'slime,' whether it came from a tube-mill or grinding pan. As some basis had to be made for comparison, this was thought to be the fairest, and the returned slime which causes Mr. James so much worry is in reality very fine sand. In the Ivanhoe report the return feed is spoken of in every instance as 'sand,' and, as shown, both tube-mill and pans had their complement of it. If in place of writing contradictory statements, Mr. James would set himself the task of defining what slime is, and, having satisfied the mining community on that point, he then invents some simple appliance which would eliminate that slime, and only sends back to be re-ground that part which according to his definition required it, then perhaps further trials may be undertaken between grinding machines that would satisfy even the most critical.

The fact of the Ivanhoe tests being checked by a tube-mill expert sent by Messrs. Bewick, Moreing & Co., from the Oroya Brownhill mine, is sufficient to remove any chance of bias on the part of those responsible for the figures given.

Coming now to the cost allowed for flints and liners—which Mr. James remarks as being excessive—I can only state that the costs shown were based on the consumption experienced during the progress of the experiments and which agreed closely with results obtained on a large scale on neighboring mines, and that, as shown later on, the longevity of liners in the Kalgoorlie district is unique. Leaving out the difference in wear and tear of working parts, the question of a pan being superior to

a tube-mill in breaking down coarse sand is so evident that it is hardly worth discussing.

It comes as a surprise to those unacquainted with fine-grinding operations at Kalgoorlie that iron liners should still be in use, but when we consider the records put up there on hard sulphide ore, one-inch iron liners lasting from four to six months, or longer than three-inch silex liners do on the Rand, it is perhaps no wonder that Kalgoorlie metallurgists are reluctant to discard such a useful friend. The reason for the great difference in wear in liners between two such important mining centres is worthy of careful investigation. From knowledge of both Kalgoorlie and Rand practice I would say that the sand of the latter place is much sharper, and also the fact that the product entering the tube-mills on the Rand is coarser on account of it practically only passing through once, while Kalgoorlie mills in grinding to a slime have a large percentage of original feed returned again and again, and in consequence the feed entering them is much finer. Another peculiar circumstance is that, while it is difficult on the Rand to find a tube-mill under 22 ft. in length, in the whole of Western Australia there is no mill over 16 ft., the majority being but 13 ft. long!

A practical proof of the esteem in which grinding pans are held is that about 200 are now engaged in Western Australia, 40% of this total in grinding raw sand, admittedly not to a slime, for those mines which are sliming their total product had tube-mills erected or on order before the remarkable grinding ability of pans was recognized; but where it has been decided to increase the capacity of these latter plants, pans have invariably been installed in preference. It is perhaps worthy of notice that about a dozen have also arrived or are on their way to South Africa.

It is a matter of sincere pleasure to those responsible if in the smallest degree the increased use of grinding pans has been due to the Ivanhoe experiments, and also the recommendation to millmen of a grinding machine that (to use Mr. James' own words) has the advantages over tube-mills of "using less horsepower per unit, their greater convenience in working, their capacity for amalgamation, the granular (?) nature of their product," and it may be added (until demonstrated otherwise) their undoubted superiority in breaking down coarse sand, and their more than equal success in sliming.

H. T. BRETT.

Sabiwa Mine, Gwanda, Rhodesia, October 4.

Milling Gold Ores.

The Editor:

Sir—Mr. Algernon Del Mar, in his valuable contribution on stamp-milling in your issue of November 17, emphasizes the superiority of the single stamp, as a mere crushing device, over the five-stamp system. This appears to confirm the claims made by the inventor of the Nissen stamp in your issue of April 25, and raises a question of the greatest significance and interest. According to Mr. Del Mar, the single stamp, by virtue of its more extended screen-area and the facility with which the pulp is ejected, will crush more than one of the units of a five-stamp battery operating under the most favorable conditions. The writer further asserts that the gain in crushing capacity more than compensates for the increased labor and wear attending the operation of the single unit. These statements suggest the query: Will not the single stamp eventually supplant the present type of battery in all cases where inside amalgamation is unimportant, and where a maximum crushing capacity is desired? A significant fact in this connection, and one which no fair-minded engineer will ignore, is that a very large battery of single stamps is now being

installed at one of the Utah smelters, after what purports to be a fair competitive trial. I am informed that several smaller orders have been placed for single-stamp mills in Nevada and elsewhere.

This is a subject which merits the serious attention of millmen and a most thorough discussion. I am not aware that any data has been published on the single-stamp battery in actual service. In a mill at Goldfield three Nissen stamps are doing hardly better service than ordinary stamps, and much less than was expected of them.

It would be interesting to know the experience of millmen who have operated the single stamp. The subject is one of great interest to metallurgists; and in view of the apparently extravagant statements made by manufacturers of the single-stamp battery, we should have complete and authentic information.

F. L. BOSQUI.

San Francisco, December 8.

Architecture in Mining.

The Editor:

Sir—In your issue of September 1, you have a short article entitled 'Architecture in Mining,' the purport of which is to draw the attention of the mining fraternity to the lack of adornment in their mine and mill buildings.

It is true that in English-speaking countries in mining structures very little thought is seemingly given outside of practical utility; and in such an industry as mining—where often lack of assurance of a long life combined, at times, with an out-of-the-world location are important factors—I am not sure that this attitude is altogether amiss or that it could be advisedly amended by the introduction of 'architecture' in mining. Coming from such an ornate-loving people as the Spanish-Mexican and being familiar with the richly ornamented design of almost all their constructions, it certainly does strike one that the Northern nations might yield a little more practicability to elaboration. But whatever I may at one time have thought of this subject, I confess I am no longer of uncertain mind since coming to the Czar's Holy Empire, for here ornamentation is carried to excess and both masons and carpenters seem never so happy as when they are developing an ornate cornice or fluting a door or window, or putting in some 'frill' or other, and this with no respect to the manner of work or building. Hence the curious anomaly of the boilers reposing in a palatial stone front and the writer inhabiting an humble adobe, which might be forgiven had not these unessential features consumed an abnormal period of a short working season.

My old father-in-engineering used to impress on me that "what is best looks best," and I am of the opinion there is a whole lot of truth in that homely maxim.

Take the examples given of 'La Presa de los Santos'. These pedestaled images really are, pure and simple, 'excrescences' and form no part of the dam proper at all (however well they may illustrate its euphonious appellation), any more than the old-fashioned figurehead epitomized the graceful lines of a clipper-ship. The easy flowing lines of a finely designed ship are beautiful in themselves and need no such appendix as a figurehead. The sinuous curves of a well-designed dam afford both a practical construction and become a veritable poem in stone. Barnacles would not improve the former nor graven images the latter. Nay, rather one would detract seriously from the speed and the other be disturbing to an appreciative contemplation of a simple scientific construction. After all is said and done, mining is a practical business. Good engineering is not only qualified by the work done, but he who can achieve the same result at the lesser cost—without sacrificing any

essential—is assuredly the better engineer. Monetary consideration is usually, if not all important, still the most important. Times have changed and mines are worked out as rapidly as is consistent with their magnitude. Elaboration was all very well when the wheels of time ran slowly—now utility is the foreword.

On the other hand, I am of the opinion inasmuch as we follow nature, which happily combines practicability with simple beauty, and seems to abhor a straight line as it does a vacuum, that always when one design is as cheap as another—and there remains but the matter of the personal equation—a refinement in taste is to be preferred and commended to a tasteless utility.

Simplicity of design, not elaboration, is the mark of the highest refinement, not only in the individual, but relating also to the construction of materials. Taste, therefore, in design rather than ornamentation, and scientific construction rather than 'architecture', which, according to the maxim I have given, if it "is the best, will look the best".

H. E. W.

Akmolinsk, Siberia, October 28, 1906.

PRODUCTION OF TIN.—The use of tin is steadily increasing and the demand for it is constantly growing. While new localities are being discovered from time to time, and while certain of the districts already known are increasing their output, some of the important tin-producing regions of the world are on the decline and others do not give promise of long maintaining their present production. The reserve stocks held in various parts of the world are accordingly being greatly depleted and the price of tin is gradually rising. For these reasons the discovery of a new tin locality is of much interest to mining men, and to many who are more or less directly connected with the metal industry, as well as to investors. The fact that the United States consumes over 40% of the world's output while contributing an inappreciable amount makes of especial interest any information regarding a tin locality that gives the least promise of becoming economically important. Previous waves of excitement have arisen on several occasions, only to wane and finally die out because of the failure to demonstrate the presence of valuable tin deposits. South Dakota, Missouri, California, Virginia, and Alabama afford notable instances of this and the Carolina tin belt itself has once risen to prominence and then almost passed from memory. Within the past couple of years interest has been revived in this region and it is now attracting a good share of attention from the outside, while within the tin-bearing territory considerable excitement prevails.—L. C. Graton, U. S. Geological Survey.

ELECTROSTATIC SEPARATION OF ORES.—When a particle of galena or pyrite that is a good conductor passes through an electrostatic field of great intensity, its potential is zero, but when it comes in contact with a charged pole it instantly rises to the same potential, and as equilibrium is established repulsion takes place. A particle of mineral that is a non-conductor, such as quartz or blende, on striking a charged pole is slow to assume the same potential and little or no repulsive force results. The ferro-magnesian minerals and others of medium conductivity possess intermediate characteristics. On these phenomena depend the principles of electrostatic separation. Although induction modifies this effect somewhat, the above principle is that on which the many types of electrostatic separators depend. In this process, which must not be confused with magnetic separators, the ore must be dry and finely powdered so that the particles of each mineral are freed.

The Later History of Guanajuato.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

The mines of La Luz were in bonanza in 1842 and for many years after, so that Guanajuato itself became less important, but twenty years later Francisco Glennie took charge of the Rul estate and by his skill he made these mines on the Veta Madre more productive than they had been at any time since the palmy days at the close of the eighteenth century. The Valenciana was unwatered to the bottom at 1,800 ft. and a new orebody was discovered in the Merced* vein. At the same time Glennie developed the Cata mine and found the rich Juanita* vein. When he became invalided, in 1890, another period of depression ensued at Guanajuato. All the company work at the Valenciana was stopped and the water was allowed to rise. At the Cata, the water was kept down, but here,

M. E. MacDonald, assisted subsequently by his brother, Bernard MacDonald.

In 1902 the Guanajuato Power & Electric Co. was formed by a group of mining men at Colorado Springs, on the initiative of Leonard F. Curtis; he was ably supported by George Bryant and George W. McElhiney, to whose financial ability are due several of the most important enterprises in the district. As fuel of any kind was very expensive, the introduction of power at a reasonable price was an important step in the progress of mining. This was accomplished in November, 1904. The electric energy now used at every large mine in the Guanajuato district is obtained from the river Duero, in the State of Michoacan, 101 miles distant. This power at 185 pesos per h.p. year† replaced wood at 8 to 10 pesos per metric ton and stone coal, from Las Esperanza, in Coahuila, at 20 to 24 pesos, delivered.

The next enterprise of importance to be started was

The Reduction Works of the Guanajuato Con. Mining & Milling Co.

as at the Valenciana, the workings were handed over to the tender mercies of the *buscones*. These are tributers on a small scale, that take a lease from week to week without any written contract and divide the ore they get with the mine-owner, who provides the tools, powder, and blacksmith. On each Saturday morning the *buscon* sorts his ore, arranging it in two equal piles, of which the foreman takes his choice on behalf of the owners of the mine. Of course, the *buscon* cannot afford to explore, he does no dead work; and as he moves no more waste than is necessary, the workings soon become choked with refuse. He nibbles at every pillar left to support the old stopes, and causes caving that will close the mine or portions of it, permanently.

And so mining came down to a dreary unprogressive level, with no new work and no fresh discoveries of ore, until in 1898, another revival was inaugurated by the enterprise of a few Americans. In that year the Guanajuato Consolidated Mining & Milling Co. secured the Sirena mine and erected a modern mill, under the direction of

the Guanajuato Reduction & Mines Co. The history of the mines that it acquired has been mentioned, they included the property originally belonging to Obregon, the discoverer of the Valenciana, and from his descendants by intermarriage they passed to the noble family of Rul. In 1860 the Señora Perez Galvez, then head of the house of Rul, began a clever campaign, the purpose of which was to obtain *avios* or perpetual leases on these mines, including the Valenciana, Cata, Tepiac, and Mellado. By the *avio* she was able to charge all expenditures against the mines, crediting them with the money received from the sale of ore, but by building large works or *haciendas*, she made contracts with herself to purchase the output of ore, deducting high rates for treatment and mixing the rich with the poor ore so that the expenses of mining were always in excess and steadily increased the debt against the mines, while permitting of handsome profits at the *haciendas*. The options to these contracts or *avios* were acquired by Messrs. Bryant & McElhiney, and transferred by them to the Guanajuato Reduction & Mines Co.,

*These were special segregations of rich ore in the Mother Lode.

†This is the average price. The lowest price in the district today is \$85 per h.p. year.

which finally bought them outright. According to Mexican law, if at any time the mines get into bonanza so as to make big profits from the sale of ore, the lessee has the right to take all such profits, without any division with the owners, until the entire accumulated debt—about six million pesos—is paid, thereafter dividing the further profits according to the terms specified in the lease; in plain English, the original ownership is a legal figment. Besides acquiring these old contracts, the promoters mentioned had the foresight to ‘denounce’ or ‘locate’ claims covering the dip of all the important properties on this part of the Veta Madre; that is, they secured the ‘deep levels.’ Finally, after expert examinations and reports had been made by such men as Carlos Van Law, Robert T. Hill, and Louis Noble, these properties and all their rights passed under the control of the Guanajuato Reduction & Mines Co., in November, 1904.

Since then other ventures have been organized and started, but their story is in process of making and must be left to a later record.

On the morning of November 2,* a party was made to visit the old mines of the Veta Madre. We formed an imposing cavalcade, for it is the custom in Mexico for each horseman to be accompanied by a *mozo*, who serves as groom on ordinary occasions, and is a courier and general servant when going across country to the mines at a distance. These men wear the wide-brimmed *sombrero*, fancy leggings, and big spurs, so that they are picturesque if nothing else, and on an occasion of pleasure such as this was, they gave a touch of gaiety to a group of horsemen, most of whom were as properly accoutred as in Chapultepec or Central Park. There were ten of us, and eight *mozos*, so that when we clattered down the narrow cobble-paved alleys of the old Mexican town, we made noise enough for a regiment, scattering careless wayfarers and awakening echoes under arches that had seen many invasions much less peaceable. The well-bred Mexican is a splendid horseman, but the inhabitants of such a town as Guanajuato are, of course, content to go afoot, so that accompanied as I was by a group of engineers and metallurgists, it occurred to me that there was a simile to be snatched from the scene, the technical man being the fellow on horseback, progressing confidently (usually with less noise), while the rest of the world is content perforce to go on foot. Well, my friends rode several hobbies, not to mention spirited steeds; one of them was the application of the cyanide process to silver ores; and their horsemanship was good either way. On arrival at the lower end of the town, I was shown the Hacienda de Bustos, where the Guanajuato Reduction & Mines Co. is remodeling an old reduction works to the needs of a modern equipment, as the accompanying photograph will illustrate. This *hacienda* is about a hundred years old; in pulling down the walls to make room for the concentrator floor, there was found a system of older unconformable foundations, and in the angle made by two walls of ancient date, the workmen unearthed half a dozen complete skeletons, with a bullet hole in each skull, and so placed as to indicate that the originals were pistoled while lying down. However, this gruesome find did not hold our attention long, for the foundations of the new stamp-batteries and the steel framing of the ore-bins afforded more cheerful subject for thought.

In the erection of the Bustos plant, bedrock was everywhere available, and the heavy masonry walls were built cheaply by Mexican labor, which is particularly skilled in such work. The stamps are of 1,050 lb. weight. The mortars are of El Oro type and weigh 9,000

lb.; they rest upon massive concrete blocks laid in Dyckerhoff cement. The concentrator room is spacious, being covered by a well-designed roof-truss of steel construction. The tailing from the Wilfley tables runs into a concrete launder, which extends down the longer axis of the concentrator room to the centre of it, delivering its contents to a tunnel at right angles and thence to the cyanide annex. While the plant was in course of construction, a 5-stamp battery, with its cyanide annex complete, was being employed for testing the various ores destined to be delivered to the works when finished. Even when the 80 stamps are at work, this small addition will be kept in service, for experimental purposes. In the concentration department of this testing plant there is a Wilfley table, a Gilpin county bumper, and an Overstrom table. After being crushed under the stamps, the pulp passes over one of the three machines just mentioned and then to a sump, whence it is pumped 60 ft. to cone-separators. The sand undergoes percolation in vats 8 ft. deep and 8 ft. diam., provided with the Butters hydraulic distributor. The slime is agitated in vats 9 ft. deep and 8 ft. diam.; one vat using the Hobson aeromechanical agitator and the other a Butters pump with mechanical stirrers. Thus the testing plant is designed throughout to duplicate the conditions under which the big mill is to be operated.

The Bustos mill is planned so that it can be doubled conveniently; in fact, excavations for that purpose were under way at the time of my visit. A sufficient space will be cleared at the back of the existing plant to allow of the erection of a second row of 80 stamps on the other side of the bins. A concentrator room, identical with the existing one, will be added, so as to make the plant a 160-stamp mill of back-to-back construction.

Owing to the high price of American lumber when delivered at Guanajuato, and the poor quality of the Mexican material, it is considered economical to use steel. The skeleton of the bin is of 15-in. channels placed back-to-back in bents which are on approximately 6-ft. centres, the vertical channel posts being tied together at bin-floor level by two 15-in. channels, which are braced from the feet of the posts by inclined struts composed of four 5 by 3½ by ¾-in. latticed angles. The thrust which these inclined struts carry to the feet of the posts is taken by two 8-in. channels acting as a tie between the feet of the posts, thus trussing the whole and making the strains on the masonry wholly vertical. As the weight in the bin is about 2,500 tons, exclusive of the bin itself, the feet of the columns are supported upon a grillage of six 5-in. I-beams, two feet long, held together by plates riveted to the top and bottoms. This rests directly upon the masonry. All the bents are braced together longitudinally at the top and floor-level of the bin by 8-in. channels and heavy angles; at the ends of the bin the outward thrust upon the bents is taken by a truss-member at the top of the bin. The bents themselves are tied together at the top by ¾-in. plates 4 in. wide, riveted between the channel-beams to the posts. Within this skeleton is a lining of plank, 4 in. thick in the bottom courses, with an inner sheathing of 2-in. plank with the grain vertical. The bin has a flat bottom supported on 4 in. by 14-in. joists on 12-in. centres, carried upon horizontal members of the steel bents before mentioned, on the top of which is laid a 3-in. plank covered by a 2-in. lining. The entire construction does credit to the manager, Mr. Carlos W. Van Law.

While we examined the mill, an interesting discussion arose regarding the comparative value of the mechanical conveyor. Cars were advocated as economical because the cost of power alone (apart from repairs, maintenance, and interest on capital) for the conveyor exceeds the

* In 1905.

expenditure for labor when employing cars *plus* human labor. A conveyor requiring 7 h.p. at \$7 per h.p. per month is equivalent to, say, \$50 or 100 *pesos* per month. The same work can be done by two *peones* at 50 *centavos* per day, equivalent to 30 *pesos* per month. In case a *peon* wears out, you can get another without absorption of capital! But alas for such calculations, the *peon* does not work on feast days! There is a great advantage in employing machinery that goes forward without any stops. For in Mexico there are 25 *fiestas* per annum that are rigidly observed, besides Sunday and San Lunas or St. Monday—sacred to sobering observance—so that there are at least 75 days of interruption in a year, and

wall, exposed in the bed of the stream, there is a quartz vein traversed by black streaks of argentite that dip at 45°; and under this ore comes brecciated schist cemented by quartz, the latter diminishing until the schist exhibits a ramification (*ramileo*) of stringers, the dominant members of which are parallel to the foot-wall. Beyond this point, the quartz continues to decrease, and on the further side of the stream the schist appears in the regular laminae to which it owes its name of *hoja de libro*, or book-leaves. This is the main foot-wall country. Remounting our horses, we returned down the cañon, soon reaching the Rayas church, a beautiful remnant of the loving architecture that the Spaniard lavished even on his

mines. In these churches are found all sorts of queer pictures celebrating the thankfulness of the donor for deliverance from various perils. In them the miner testified to the danger of his calling, by the tribute offered to his particular saint.

Ascending the hillside overlooking the church and its environing buildings, we turned to look on the crumbling walls of an old *hacienda* that we had failed to notice as we rode past it. The walled enclosures seem inadequate for protection, and yet they served their purpose before long-range rifle practice was developed. Until about twenty-five years ago, brigandage was so rife in this, as in other parts, of Mexico, that the *haciendas* or reduction works were periodically 'held up,' more particularly those in outlying districts. As regards Guanajuato, their special nest was at El Capulin, on the road between Silao and Marfil. They terrorized the country, and despite occasional raids from the military, who drove them into the hills, the bandits would return after a short interval, to resume their depredations. Finally, in 1883, the State Government sent a body of mounted police to clean them up. Sixty men were captured, placed against a wall and shot. El Capulin was completely destroyed; not a hut was left to mark the spot. That ended the business.

Passing close to the flying buttresses of the magnificent walls that enclose the San Miguel shaft of the Rayas mine,

we entered the old enclosure. A suggestion of the appearance of this architectural survival is presented by the accompanying photograph.

A little further and we entered the courtyard of the Rayas shaft, one of the four great openings on the Veta Madre. This one is octagonal in shape, and 38 ft. in diameter. The depth is 1,400 ft. Why these shafts were so big and the manner in which they were operated, will be told in the sequel. They make even the most self-confident American miner realize that his science did not begin at Virginia City, nor was it born in Colorado. The Rayas was sunk by the Spaniards in 1850, while the Valenciana shaft is a hundred years old, and yet one can read in the mining papers of forty years ago that there was jubilation on the Comstock when the Ophir shaft reached 400 ft., and that doubts were entertained whether there would be machinery able to cope with any greater depth. Yet eventually the men of Nevada went down 3,250 feet.

The Bustos Plant of the Guanajuato Reduction & Mines Co. in Course of Erection.

wherever laborers are not plentiful, this feature must be taken into account. On the other hand, if one has a bin capable of holding a ten days' supply of ore for the entire plant—as is the case at the Bustos mill—the bad effect of two or three days of *fiesta* is obviated. Of course, where a car-track is impracticable or where elevating is required, the conveyor holds the field—and that is often.

Leaving the Hacienda de Bustos, we rode up a ravine leading to the mines on the great lode of Guanajuato, called the *Veta Madre*, a term which in the guise of 'Mother Lode' has also been applied to the main vein system of California. In the State of the Argonauts it refers to a general zone or belt several miles wide and 300 miles long, but at Guanajuato it defines a distinct lode channel about 600 ft. wide and seven miles long. At the foot of the hill on which stands the Rayas mine, the *Veta Madre* is crossed by the Cañon de Zapote, and a natural section of the big outcrop is visible. The lode consists here of eight feet of silicified breccia; on the foot-

Metallurgical Accounts, III.

Written for the MINING AND SCIENTIFIC PRESS
By PHILIP HENRY ARGALL.

METALLURGICAL REPORTS AND ACCOUNTS.—With the receipt of the copy of Inward Receipts Book, Fig. 1, from the Sampling foreman, the Refinery Receipts, Fig. 10, Parting Plant Receipts, Fig. 12, the particulars of ore, bullion, etc., received by the three departments, such as name of consignor, class, number of bags, weights less bags, date sampled, lot number, disposition, etc. are entered in the Ore Purchase Record, Refinery Purchase Record, and Parting Room Purchase Record. These are kept in an elaborate manner in book form, giving all details and data possible in connection with each lot of ore or bullion. Each lot may be entered numerically,

to the Margin Tag, and the contents of such lot are figured without deduction of any kind whatever. The price for the contents on the Margin Tag may be estimated, basis of estimation being previous realizations, or it may be figured at the current quotations. From the total amount then shown is deducted the amount due to the shipper, plus any other charges, such as freight, etc., which increases the cost of the lot to the smelter, the balance is the total margin, from which is made the loss or profit, in addition to any gain that may be made on prices at which the refined metals are sold. The margin per ton is found by simply dividing the total margin by the total net dry weight in tons. The figures on both Settlement and Margin Sheets are then checked by another clerk, and if found correct, they are copied, the Margin Tag torn from the Settlement Sheet and sent to

Fig. 20. PRODUCTION AND SHIPPING RECORD.

but they may also be classified, for example, consignments coming from a certain locality or State, or from a frequent and large shipper, etc.; but this, of course, gives more work. If these records are kept by one clerk the use of a loose leaf binder with special forms for each department is recommended. Fig. 17 shows a form for the Ore Purchase Record, which has been found to answer all requirements. Records for the other department would be somewhat similar.

The balance of the records is filled in after Fig. 2, Weight & Assay Sheet, has been received from the Laboratory and Settlement and Margin Sheets made out. This gives the first check on the correctness of the work already done, and the weights shown on the Weight & Assay Sheet should be compared with those already entered from the Daily Receipt Sheets.

The Settlement Sheet, Fig. 18, is made out for the consignor, giving full particulars of shipment. To this is attached the Margin Tag by a perforated line, so that it may be torn off. The settlement is made out on the basis of the assay and terms either specially quoted, or those usually in force for the particular class of ore or bullion under process of settlement. This being completed, the total net weight, assay, total contents are carried down

the metallurgical clerk. The Settlement Sheet is forwarded in due course through the cashier to the shipper with remittance, and the transaction becomes merged in the financial book-keeping.

The value of the metal contents in the Purchase Records is the value as shown on the Margin Sheets. The total value of the metals should equal the total cost, including all charges, plus the total margin. If these columns do not check, something is wrong, and the work must be gone over again. Each month's cut-off is made to agree with the plant's cut-off, and the purchase as shown by each department, as will be explained later, should correspond with the total purchases as shown in each of the Purchase Records; also the total of the entire plant's purchases should check out the total of the various Purchase Records.

On receipt of the Margin Tags, the metallurgical clerk places them on a file, so that they may be had immediately they are wanted. On receipt of copy of the daily Distribution Sheet Fig. 4, from the metallurgist, showing the bed or mixture to which certain lots have been sent, he proceeds to make up his Bed Sheets. The beds are simply the mixture of certain ores in order to make the smelting operations yield the best results, and the

Bed Sheets show the contents and analyses of such ores, together with lot number, name of shipper, cost, and margins. On completion of a bed—that is, when no more lots are added, the mixture is totaled, and the average assay and analyses are shown. This information, if

in his Ore Purchase Record in columns provided for that purpose in order to show the distribution.

Roasting mixtures are not completed until after the mixture has been roasted—that is, the average assay and analyses are not calculated out. After such a mixture is

check on ores smelted, and checking the correctness of the total purchases as made up by the settlement clerk.

The particulars for the Roasting and Smelting Mixtures are taken from the Margin Tags. These tags are then kept together for the time being according to the number of their mixtures. The number of the bin to which the ore is sent, and the mixture in which such lot is put, is passed on to the settlement clerk, and is entered

The difference in the contents of the mixture before and after roasting is either loss or gain in roasting. The gain or loss per ton is shown by dividing the total loss or gain by the total weight of the mixture before roasting. The new weight and contents of the mixture are used in completing the mixture for the blast-furnaces, to which are added any further lots or by-products that may be put in the bed. When completed, the figures

month will show a corresponding loss. When, however, any complete clean-up is made the difference either way may be accepted as being almost the actual figures.

Having shown how the metallurgical balance is arrived at, it is now necessary to find out the cost of smelting, refining, and parting. To do this it is necessary to go back to Fig. 1, the first report of the sampling foreman, and enter from there the Fuel & Fluxes (limestone, ironstone, coal, coke, oil, copper plates, sulphuric acid, zinc, etc.) received. Prices of such materials are obtained from the various accounts rendered. A special book is required for this, Fig. 22. At the end of each month the respective columns are totaled, and amounts used by the various departments, as shown on the various daily reports, deducted, such amount being charged to the department using the material. The quantity of fuel used by the boilers is proportioned over the plant, according to the number of horse-power hours used during the

month by each department. This information, of course, comes from the chief engineer, who fills in Fig. 23, at the end of each month. Where electricity is used, the same would apply. The next item to be considered is that of stores and supplies. It is the best in every way for the plant to have a storehouse, and storekeeper, who receives, checks, and is responsible for the goods placed under his care. Under no consideration should he deliver goods to anyone without a signed order from a foreman or responsible officer, and these orders should form the basis of his entries and charges to the various departments. Fig. 24 shows a form, simple yet effective, for this purpose. At the end of the month the storekeeper should total the value of stores charged to the various departments, and make out his monthly statement.

The monthly statement covers the whole of the accounts in his Store Ledger, which in turn covers those of the Financial Ledger. The simpler the form the less time is occupied in compiling it, but there is always more or less detail, so that the cost of the various operations can be arrived at if necessary. Fig. 25 shows a form that may be used, but if necessary it can be modified to suit any requirements. General items, such as fire apparatus, runways and tracks, laboratory tools and supplies, power, etc., are divided over the plant. When completed, this report, together with the sheets from his loose-leaf binder (assuming that he is working with the loose-leaf system, which is generally preferable) are sent to the office to be checked and passed. The next step is the time. The simplest way of keeping check on the time is by the Time Check Fig. 26.

Throwing the responsibility of putting in his own Time Check on each man, relieves the foreman and timekeeper of considerable work. If a man has been employed on half a dozen jobs during any one day, and in different departments, it should be itemized on the Time Check, and approved by the foreman of the gang to which he usually belongs. Being filled in by the man himself, there can be no claim for short pay when pay-day comes around. As with the storekeeper, the timekeeper would enter up his time in his Labor Distribution Book to the various departments from the Time Checks, from which he would also make up his Pay-Roll. The total of his Pay-Roll should check the total of his labor distribution; thus correctness of work is ensured. At the end of the month the columns are totaled, and the monthly report is made out, and sent in to the office for checking and approval. The monthly report would be itemized as with the Store Report, and the labor employed by the various departments would also be kept distinct. Fig. 27 shows a form that will answer this purpose.

General items, such as power-house labor, watchmen, etc., are apportioned as with the stores. Any cost for new construction or improvements cannot be charged direct to any particular department on the monthly statement, as it would swell the cost of treatment for the particular month in which it is incurred, out of all proportion to the actual cost of treatment for such month. It is only when such new construction or such improvements are in daily operation that their charge of operation and maintenance becomes a direct charge to the department to which they belong.

With the data now in hand, it is a simple matter to make up the cost per ton of ore smelted, the cost of treatment per ton of ore refined and parted; the cost of production per ton of lead, per ounce of doré bullion, and per ounce of fine gold and silver. The cost of sampling, roasting, briquetting, crushing, and handling matte, as well as the cost of fuel and fluxes used. Fig. 28 shows how this is made out.

In explanation of the foregoing statement it might be well to state briefly where the figures are taken from:

Ores Sampled..	{	Weight from the Daily Operating Record.
		Labor from Timekeeper's Monthly Report.
		Stores from Storekeeper's Monthly Report.
		Total cost is the total of the two preceding columns.
		Cost per ton is the total cost divided by the weight.

Ores Crushed, Mattes Crushed, Ores and Mattes Roasted. Briquetting, and actual Smelting. Figures are taken from the same reports as Ores Sampled.

Ore Matte, and Bi-products smelted, with contents, are found on the Mixture Sheets.

Fuels and Fluxes used, are taken from the Fuel and Flux Record after it has been made up for the month.

In the cost per ton smelted, average cost per ton lead refined, and average cost per ounce of gold and silver parted, the wages and stores are taken from the Store-

Cornishmen in Evidence.

Our London correspondent has sent us an interesting photograph of one of the floats in the Lord Mayor's show. This annual event is a historical and industrial procession that parades the streets of the city of London on the day, each year, when the new Lord Mayor goes into office. This year the Mayor of London is a Cornishman, Sir William Treloar, and by his suggestion the pageant of November 11 included a car carrying a group of Cornish miners, who gave an exhibition of rock-drilling, as they progressed with the procession. The men were stalwart students from the Truro School of Mining, in charge of Capt. J. S. Henderson. The exhibit was a notable success.

THE ANEMOMETER of R. Goldschmidt, a Belgian electrician, depends upon variation in electrical resistance

keeper's and Timekeeper's Monthly Reports. The proportion of salaries, interest, and general expenses are obtained from the cashier.

The statement of Particulars and Cost of Operations completes the Metallurgical Bookkeeping of the Plant. From now on the metallurgical becomes merged into the financial records of the concern, which, as already mentioned, do not need explanation here, as they embrace the usual phases of accountancy. With some plants it may be necessary to include other items on the various reports submitted; it may also be necessary to particularize and itemize the reports more, but throughout if the system as outlined, is followed systematically, methodically, with stringent exactness, it should meet every call on it, and each report will fit in its proper place, forming a harmonious whole, and when completed the reports present a compact, concise, and presentable statement of operations and cost.

[The first two parts of this article appear in the issues of November 10 and December 15.—Editor.]

due to the cooling by the wind of an electrically heated platinum wire. To compensate for the changing temperature of the air itself two similar wires are used, and these form arms of a kind of wheatstone bridge, which is so adjusted that when the two wires are of equal resistance the galvanometer is at zero. After this adjustment, the cooling of the exposed wire—the other being protected—varies with the wind. The galvanometer—which may be at considerable distance away—is correspondingly deflected, and gives a direct reading of the wind's velocity, the indications having been accurately calibrated by driving one of the instruments on a rotating stand through calm air at a series of known speeds. With a recording galvanometer and an electrical weathercock—the latter acting through changes of contact on a circular slide wire—a permanent record can be kept of both the velocity and the direction of the wind.

Most people are like the man who needs a jack-knife; if they want an opinion they borrow it.

The Right to Minerals on Railroad Lands.

Written for the MINING AND SCIENTIFIC PRESS
By COURTENAY DEKALB.

An agitation has been started in the State of Nevada to secure legislation permitting the valid location of mining claims on railroad grant lands by outside parties, under the plea that the right of eminent domain may apply in view of the fact that the chief interests of the State lie in its mineral wealth.

The question is one of importance to other States as well, and if Nevada can solve the problem by a statute which shall be held to be constitutional by the Supreme Court, a condition which has worked much hardship, and has retarded progress in many parts of the West, can be done away with.

The intent of Congress at the time of making land grants to the projected trans-continental railroads is perfectly plain from the express reservation of mineral lands from these grants. The alienation from the general public of large areas of mineral-producing territory was not contemplated, but the railroads took advantage of the provisions for having lands upon which valuable minerals had not been discovered, classified as agricultural lands by the Land Office, and proceeded to acquire title. This was accomplished perfunctorily for the most part, without investigation to establish the fact whether or not valuable minerals did exist on the lands for which titles were issued. It is true that surveys were made, but these disclosed nothing as to the character of the lands. It is also true that considerable areas remain unsurveyed where prospecting may be freely conducted, but such areas are mostly remote from the railroads, or else exceedingly inaccessible.

Formerly the railroads, in selling their lands, conveyed both surface and mineral rights, which went far toward mitigating the evils which have now become the object of complaint. At the present time it is the custom of the railroads to reserve the mineral rights, so that in effect the resources of important areas are completely locked up. It is difficult to see any legitimate interest which the railroads can have in the adoption of such a policy, since it deters settlers from buying land on account of the incompleteness of title, while on the other hand it is inconceivable that a corporation would risk the great expense of systematic prospecting and development necessary to prove the mineral values of its holdings. Prospecting is a function of a special class, willing to consume the earnings of a portion of each year in the quest of fortune during the remainder. Figured in terms of normal miners' wages and costs of supplies, the annual expenditure in the Western States in chasing the golden will-o'-the-wisp, can be counted only in millions of dollars. It used to be commonly asserted that the costs of prospecting plus unproductive mine development were twenty times greater than the net spot value of the total mineral output of the Western States. Though this may be an exaggeration, it would not be surprising to find that our production of metals was actually won at a loss.

If the railroads would adopt a broad policy, conceived in recognition of the fact that they exist by virtue of franchises granted by the State, virtually constituting them an arm of the Government for the promotion of the general welfare, and would grant prospecting privileges, retaining only the right to a suitable royalty on the output of mines which might be discovered, it is likely that such privileges would be eagerly sought, and that the system would meet with very general satisfaction. But the policy of the proverbial dog in the manger will continue to be offensive, and the public cannot forget that it

was not intended to convey mineral rights to the railroads.

As the case now stands the prospector has no means of determining, without the very considerable initial expense of surveys, where the lines of the railroad sections lie in the great stretches of desert, for the survey monuments to a great extent have been obliterated. If he discovers a vein, he is permitted to work undisturbed until he has revealed something which affords promise of value, when proceedings to dispossess him are instituted. After numerous experiences of this character, the prospector has become wary of districts in which every odd section belongs to the railroads, and consequently the land lies undeveloped, the public domain sharing in the evil because of the lack of adequate definition of metes and bounds by conspicuous marks.

It seems very doubtful whether, when titles have once been granted by the United States, the principle of eminent domain could be appealed to as a warrant for conceding the rights of location of mining claims to one set of legal persons in contravention of the rights of others acquired by patent, even though these be corporate persons. It is possible, however, that the principle might apply if the State assumed the right to grant claims in consideration of a royalty to be paid into the public treasury, if such right of location were made operative on all lands held in fee simple, without distinction of classes or persons. A precedent for this could be found in some of the Eastern States, the State of New York being a case in point, where the discoverer of veins of gold, silver, and certain other metals, is entitled to enter and operate the same, making an annual accounting to the original owner of the land, and paying him one-half of the net proceeds. But such privileges in the Eastern States are a relic of the colonial charters which affirmed the right of the crown to the monetary metals. Whether this ancient theory of sovereign prerogative could be extended to the newer States of the Union is a question for the legal fraternity to decide. If it could be done it would make strongly for the general good, not only of the public, but of the railroads themselves.

SCIENTIFIC INTEREST, with the possibility of great economic value, attaches to the discovery, by Dr. James Moir, of a new solvent for gold. It is thiocarbamide and is efficient in a slightly acid solution, a feature which renders it attractive to those that are treating old dumps or oxidized pyritic ores. The present price of the salt is high, but should there be a demand for it, new methods of manufacture are likely to be found.

QUICKSILVER IN TEXAS.—The greater part of the quicksilver produced in Texas has been obtained from shallow workings. That the easily accessible deposits should be utilized was natural; they were near the surface, rich, and cheaply mined. These surface deposits have not yet been exhausted, but companies now operating have commenced to exploit the ground in depth, anticipating the time when surface deposits can no longer be depended upon for regular supplies of surface ore. One company has already sunk its main shaft to 350 ft. with satisfactory results. According to present indications there is little doubt that ore may be profitably mined at as great a depth as 1,500 ft. in the limestones and 1,000 ft. in the shales, while so far as the shallow workings are concerned, it is held that there is much more quicksilver in the district to be obtained from this source than has been produced. The present mining laws are considered a detriment, the Commissioner of the General Land Office being vested with the power to fix his own valuation on a mining claim over and above a minimum of \$25 per acre.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

Certain amendments to the statutes of Nevada were enacted for the benefit of locators of mining claims, giving them ninety days in which to perfect their location, to cure defects, if any existed, in the original notice or the marking of the boundaries, mistakes in the directions, courses, etc. But the statute does not require the filing of an amended certificate of location where the original notice is clear, definite, and certain, and the boundaries of the claim so marked and monumented that they can be readily traced, in which case such notice may be filed and recorded as a certificate of location. The reason for this is that mining claims are not open to re-location until the rights of a former locator have come to an end, as two locators cannot legally occupy the same place at the same time. However regular in form a junior location might be, it is of no effect as against the rights conferred upon the prior locator, so long as the prior location is subsisting.

Porter v. Tonopah North Star Tunnel &c. Co., 133 Fed. 756.

In a case where the principal controverted question related to the sufficiency of the mineral discovery claimed to have been made by the locators to sustain their placer location, the trial court stated the law to the jury thus: "What is a 'discovery'?" What finding of mineral upon a placer mining claim is sufficient to satisfy that clause of the statute which provides that no location of a mining claim shall be made until the 'discovery' of the mineral within the limits of the claims are located? This inquiry is partly answered by the terms of section 2,318 of the Revised Statutes of the United States, in the following language: 'In all cases lands valuable for mineral shall be reserved from sale, except as expressly directed below.' It is only lands valuable for mineral which are reserved from sale for disposal under the mineral laws. Lands not valuable for mineral are not so reserved, and may, if otherwise unappropriated and unoccupied, be settled upon and used, and occupied for townsite or business purposes, or taken under the homestead or other laws for the settlement and sale of the public domain. Lands valuable for mineral are lands having value or worth for the minerals contained therein; lands containing mineral in such quantity as to pay a reasonable profit upon the capital and labor necessary to extract the mineral therefrom. Any other lands would have no value for mineral, and are not such as the statute contemplate reserving from sale for disposal under the mineral laws of the United States."

In this instruction the Court stated the correct rule that it was essential to the validity of the location under which the claim was made that the discovery of mineral thereon was such that "an ordinarily prudent man, not necessarily a miner, would be justified in expending his time and labor thereon in the development of the property." But at the same time the Court further instructed the jury that it was essential to the recovery by the claimants that "they should have proved with reasonable clearness that for the labor and capital expended in locating the ground it would yield a reasonable profit, and that, unless the jury so found, their verdict should be for the defendant." On appeal, the Court held that this latter instruction was not only not a correct statement of the law, but was also in conflict with the correct rule given.

Cascaden v. Bartolis, 146 Fed. 739.

Where a miner was engaged under a contract at a specified rate per ton for ore delivered at the mouth of the shaft, and under the contract it was his duty to run his loaded cars out of the room in which he worked to the entry and in so doing a car was derailed. The responsibility of getting the car back on the track rested upon such miner, and the proprietor of the mine was chargeable with no duty to a person injured in assisting the miner in the re-railing of such derailed car.

Cavanaugh v. Centerville &c., Co. 109 N. W. 303.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The two minerals from C. W., of Daunt, Cal., are: No. 1, brown Jasper; No. 2, earthy Limonite.

W. W. J., of Elmore county, Idaho: The large specimen is Chalcedony, and the small one opalized wood.

The rocks from Wallace, Idaho, are: No. 1 and 2, Slate; No. 3, decomposed clay rock; No. 4, Quartzite.

Specimens from F. A. F., of Tehachapi, Cal., are: No. 1, Andesite; No. 2, Quartz stained with oxides of iron and manganese; No. 3, Authophyllite, or a brown amphibole altering to talc.

The mineral sent by H. J. C. W., of Bruce Mines, Ont., is Bornite, but it probably contains an admixture of chalcocite, which raises the percentage of copper. Some chalcopyrite is also present.

The rocks from W. H. L., of Cobalt, Ont., are: No. 1, 2, 3, and 4, metamorphosed and mineralized rock, perhaps altered; No. 5 is a Diorite. The rocks are too fine-grained to definitely class them without a microscopical examination.

It is beginning to be recognized that industrial warfare is no better a regulator of business than private warfare is of social intercourse, and it is this feeling that has led to the organization of labor on the one hand and to the organization of capital on the other, labor seeking to reduce its hours and increase its earnings, and capital, which is crystallized labor, striving to prevent the dissipation of that which it has so laboriously gathered. Each is wrong in its aims when it seeks exclusive domination, both will be right when they learn that they are forces which must work in harmony to carry out the ancient command to subdue and replenish the earth. Strikes and trusts are the clumsy attempts of the giants, Labor and Capital, to carve out each a world on which he shall be sole lord. Co-operation will be the form in which they will work together when they realize, as they are coming to do, that as enemies they can only harm each other while as allies they are masters of the world.

Power prices vary widely. As a rule, power from hydraulic installations is cheapest, and power developed from coal that must bear the expense of a long railroad haul is the dearest. According to a recent report by the Hydro-Electric Power Commission appointed by the Ontario Government, \$12 per horse-power year may be assumed as the cost of developing high-tension power at Niagara Falls. Transformed into low-tension power and delivered to sub-stations throughout the province, the cost would be from \$15 to \$35, varying with the amount, distance and load. The cost of distribution from the sub-stations to the individual consumers would vary from \$2.51 to \$24.74 per h.p. year, according to the amount and the distance. The annual cost of twenty-four-hour steam plant power per brake horse-power, with \$4 bituminous coal, according to the same report, would vary, with the character of the plant and the amount of power developed from \$41.11 to \$180.76. Under the same conditions, it is estimated in this report that producer gas power would vary in cost from \$34.66 to \$90.02. For ten-hour power, developed from producer gas, the cost would vary from \$20.46 to \$53.48; for steam power from \$22.47 to \$91.16.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

CLEANER FOR BUCKETS OF EXCAVATING MACHINES.—No. 833,749; Howard Pike, Chicago, Ill., assignor to F. C. Austin, Drainage Excavator Company, Chicago, Illinois.

The combination with an excavator-bucket and means for effecting the inversion thereof, of a cleaner pivotally mounted externally of said bucket, said cleaner having an operating edge adapted to engage the forward edge of the bottom wall of the bucket and scrape over said bottom wall during the inverting of the bucket, substantially as described.

HOISTING APPARATUS.—No. 833,994; William S. Bradshaw, San Jose, California.

In hoisting apparatus, the combination of a drum having a plurality of frictional surfaces, a drive-shaft having a plurality of frictional surfaces, and means for shifting the drum relative to the shaft whereby one of the frictional surfaces thereof will engage one of the frictional surfaces of the drive-shaft and the other frictional surface of the drum will simultaneously disengage the like surface of the shaft.

ROCK-DRILL.—No. 833,875; Henry Deitz, Denver, Colo., assignor to Anna Theresa Deitz, Denver, Colorado.

In a rock-drill, the combination with a guide-shell, casing, and reciprocating yoke, of a drill-holder mounted in the casing collars loosely mounted on the holder and engaged by the yoke which is located between them, springs surrounding the drill-holder and engaging the yoke-collars, other collars surrounding the drill-holder and engaging the spring extremities remote from the yoke, the foremost collar and the rear yoke-collar engaging shoulders on the drill-holder, the collars being in the rear of the shoulders and the portion of the drill-holder immediately forward of each shoulder being reduced for the purpose set forth.

ELEVATED CONVEYOR.—No. 834,194; John W. Cooper, Seattle, Washington.

In combination with a track and a stop thereon, a carriage on said track, a hoisting-rope supported on the carriage and provided with an enlargement, a rotatable element on the carriage having a depression in its edge portion and provided with a projection receiving said rope and being adapted to be engaged by the enlargement thereof to effect rotation of said element, means secured to the edge portion of said element at a point below the projection thereof and embracing the rope after said element has been rotated, and a catch member pivoted to the carriage and having its lower portion formed to snugly engage the edge portion of said element or engage in the depression thereof and having its upper portion formed for locking engagement with said stop.

REMOVABLE POINT FOR PICKS.—No. 836,856; Cyrille Bourque, Vancouver, British Columbia, Canada.

As an attachment for picks, a removable point provided with a tapered socket, the corners of which socket are curved, said socket being adapted to receive a similarly tapered end of the head of a pick and be self-holding thereon, substantially as shown and described.

MINE-CAR STOP.—No. 836,880; John Hamilton, Byesville, Ohio.

The combination with a cage in a shaft and a track leading thereto, of fore and rear carstops connected together and movable oppositely up and down through the track, to stop and release the first and successive cars respectively, a tripper in the shaft arranged to be struck by the cage, and operative connections located under the track and extending between the tripper and the stops, to raise and lower the latter.

MECHANICALLY RABBLED ORE-ROASTING FURNACE.—No. 836,871; Thomas Edwards, Sebastopol, Ballarat, Victoria, Australia.

In an ore-roasting furnace, in combination with superimposed hearths, multiple rabbles, a plurality of lines of rabble-spindle-rotating overhead shafting, and a plurality of longitudinal series of superimposed closable apertures for insertion and removable of multiple rabbles as indicated.

The Hughes Gas Producer.

The accompanying illustration gives a sectional view of the Hughes mechanically poked continuous gas producer, which is manufactured exclusively by The Wellman-Seaver-Morgan Co. at Cleveland, Ohio. The special feature is the mechanical poker, which is a water-cooled steel casing, suspended from a trunnion. The poker is operated by ratchet gearing actuated by a crank and crank-shaft, which in turn are driven by a reduction of gearing connected with the main shaft. This mechanism moves the poker back and forth in the coal, agitating and breaking up the mass of coal, and also assisting in the distribution of the coal and the working down of the ashes for removal. Thus hand labor in poking is eliminated, and the fuel is not subjected to the variations in treatment incidental to hand poking. This uniform treatment has proved espe-

Sectional View of Hughes Patent Mechanically Poked Continuous Gas Producer.

cially beneficial, giving better and more uniform results as to quality, quantity, and supply of gas, and thus reducing the number of producer units and the size or number of buildings required for a given capacity. Under average conditions it is stated that the capacity of the mechanically poked producer will average 25 lb. per hour per sq. ft. of producer area, and that frequently 30 lb. per sq. ft. may be gasified for long intervals. The nominal capacity for the Hughes gas producer is one ton of coal per hour per producer, basing this estimate upon the standard size of producer, which is 10 ft. diam. inside of the fire-brick lining.

The main shaft and gearing are supported by steel framework securely braced to the top of the producer. The gearing is accessibly placed for removal or repairs. The producer shell is of steel plate, and is secured to a cast-iron base ring, to which is bolted a cast-iron water-seal forming an ash receptacle. The base ring rests upon supporting columns bolted to a cast-iron revolving turntable, which as it turns rotates with it the body of the producer and the ash-pan.

The bottom of the turntable is fitted with a steel tread resting on conical carrying wheels and supported by the necessary axles and boxes. As the producer shell revolves, the ashes work down and are deposited in the rotating water sealed ash pan, from which they may be shoveled direct to the car by a man standing at one side of producer, and without the intervention of machinery. The producer shell is arranged for the usual fire-brick lining. The producer top is a steel casting flanged and ribbed to provide for water cooling, a water seal being formed by a top flange at the outer circumference of the producer cover. The use of a steel casting for the producer top adds materially to its durability, as experience has demonstrated that, where parts are exposed to the heat, steel castings are much superior to cast iron and decrease the expense for repairs.

These producers are driven by electric motors, either

alternating current or direct current, as desired. The power required to operate a single machine continually is three electric horsepower. The labor required is, of course, somewhat dependent upon the arrangement of the plant and the facilities for coal and ash handling. In plants where the coal is delivered overhead into bins and fed to the producer by a hopper or other mechanical devices, six men are ordinarily sufficient to operate eight producers, or an average of three-fourths of a man per producer per turn.

An Improved Derrick Engine.

The system of hoisting with derricks passed through many stages of improvement until it reached its present state. The tag line for pulling the boom around has always been expensive and slow. Some contractors got up schemes of their own and men of inventive genius came to their aid to devise means to swing the boom with the hoisting engine. The simplest and most efficient is claimed to be the Werner & Flory patent. It supplies a long-felt need for the successful and economical operation of boom derricks. It is extremely simple and efficient. The accompanying engraving shows the arrangement of the gears and drums to swing the boom in either direction. It is independent in action from the hoisting drums, and at will the engineer can swing the boom while hoisting or lowering the load, or when the hoisting drums stand still.

It consists of a series of gears which are placed in a cast-iron frame connecting the front drum-shaft and swinging shaft. The drum-shaft projects beyond the housing sufficiently to receive a pinion-frame and winch-head. Two of the swinging gears are fitted with the Flory standard type of friction, with special compensation for adjustment. It is through these gears that the swinging drums are reversed. The entire equipment is mounted on skids so the gears clear the ground or floor on barges or docks.

The movements are effected by a single lever placed in notched quadrants between the two friction drum-levers, convenient for the engineer. The illustration does not show this part properly. Placing the lever in a vertical position, both swinging drums are out of frictional contact, and stand still; moving it forward, the drums revolve in one direction, and are reversed by moving it back over the centre. The sluing rope, of course, gives and takes, but it is always taut without the use of brake-bands. For further information the reader is referred to the S. Flory Manufacturing Co., at Bangor, Pennsylvania.

Trade Treatises.

THE BRODERICK & BASCOM ROPE Co. of St. Louis, Mo., is sending out a handsome blotter, bound in a celluloid cover, on which is a view of an aerial tramway $3\frac{1}{2}$ miles long, erected by this company in South America. This blotter will be sent on request.

Publications Received.

UNITED STATES GEOLOGICAL SURVEY. The Production of Platinum, by F. W. Horton; The Production of Bauxite and Aluminum; Contributions to Economic Geology.

THE FIRST ANNUAL CONVENTION of the Sigma Rho Fraternity, of the Michigan College of Mines, will be held at Chicago and Milwaukee on Thursday, Friday, and Saturday, January 3, 4, and 5, 1907. An important feature of the convention will be the formation of the alumnus body of the fraternity into the Alumnus Association. Various plants and works, which appertain to mines, mining, and the manufacture of mining machinery, will be visited by the convention during its three days' session. The Committee on Convention hopes to secure as large an attendance as is possible in order that the Alumnus Association may outline a future policy for expansion and growth, which will meet with general approbation, and which will be followed by success. The Committee has arranged a program, which will prove entertaining, instructive, and profitable, and has also secured privileges for the delegates which individually they would be denied.

Commercial Paragraphs.

WORD BROS., of San Francisco, have issued a handsome little circular describing their well-known drill-maker and sharpener.

JOHN H. MARKS and E. S. SNELL have opened offices at 503-4-5 Empire Bdg., Denver, and will do a general engineering business.

W. L. LOVELAND, manager of the mining-machinery department of the Allis-Chalmers Co., has returned to Milwaukee from Denver.

C. I. GLASSBROOK has been appointed local manager of the Mine & Smelter Supply Co., with offices at 9 Front St., San Francisco, California.

THE H. W. JOHNS-MANVILLE Co., of New York, announces that its Boston branch will move early in December into a new building at No. 55-59 High Street.

W. J. Spencer, special representative of the REVERE RUBBER Co. in the Western States, with headquarters at Denver with the Mine & Smelter Supply Co., is at the factory, in Boston.

THE WESTERN ELECTRIC Co., of Chicago, have issued a handsome booklet describing their new plant at Hawthorne, where they are now able to build heavy power apparatus and switchboards.

STONE & BROWN, of Searchlight, Nevada, have just issued a new and complete map of the Searchlight mining district. All the wagon-roads are shown and the surveyed claims are platted from field notes.

THE DE LA VERGNE MACHINE Co., on East 138th St., New York, has just issued a folder describing the Klein water-cooling tower built by them. These towers will cool the water to from 5 to 15° below the temperature of the atmosphere.

THE JOSEPH DIXON CRUCIBLE Co., of Jersey City, N. J., publishes a neat pamphlet containing illustrated essays upon 'The Function and Value of Flake Graphite' in air-compressor lubrication, from the theoretical as well as the practical standpoint.

Through G. & O. Braniff & Co., agents for the WESTINGHOUSE ELECTRIC & MFG. Co., Pittsburg, Pa., a large and modern electrical plant for lighting and power is being installed by the Oaxaca Smelting & Refining Co., of which O. F. Westlund is manager.

J. W. DUNTLEY, president of the Chicago Pneumatic Tool Co., sailed for Europe on November 6, for a five weeks' trip in the interest of the company's business, during which time he will visit the important trades generally in England, Scotland, France, and Germany.

THE SULLIVAN MACHINERY Co. announces the opening of a branch office and warehouse at 319 Howard St., San Francisco, Cal. The best obtainable facilities have been provided for the prompt handling of business. Howard T. Walsh will be manager of this branch.

THE POWER & MINING MACHINERY Co., of Cudahy, Wis., has issued a handsomely illustrated catalogue (No. 6) descriptive of standard machinery, furnaces, and equipment used in roasting, smelting, and refining. The designs embody improvements in mine machinery introduced by this firm.

AUGUST MIETZ IRON FOUNDRY & MACHINE WORKS, of New York, issue catalogue M5 and A42 describing their marine oil engines and gas engines, as adopted by the United States and foreign Governments. These machines have been in wide use for the last ten years and they have undergone recent improvements, making them even more simple and effective.

As an indication of the prosperity of the country the BUSINESS MEN'S CLEARING HOUSE at Denver states that of the many orders it receives from concerns from different parts of the world for accountants, stenographers, engineers, and technical men, it is only able to supply about one-half the demand. During the past year or two this company has more than doubled its capacity for handling this class of trade, and is now obliged to add another room to its already commodious office. This institution is divided into

five departments: Mining, Engineering, Accounting, Stenographic, and Mercantile, and it is prepared to secure positions for first-class men in any part of the country.

THE KEYSTONE DRILLER Co. has opened offices at 170 Broadway, in New York, as an Eastern Sales & Export office. This move has been necessitated partly by the remarkable growth of their sales of Portable Well Drilling Machines in South Africa, South America, and Russia, and also by the increase in the volume of business coming to them directly from the City of New York.

The Cieneguita Copper Co., whose mines are at Tarocho, Sonora, Mexico, has ordered of the TRAYLOR ENGINEERING Co., of New York, a reverberatory furnace, a set of crushing rolls, a Blake rock and ore crusher, and a Centripact screen. The crushing rolls and the Blake crusher are sectionalized for mule-back transportation, and other machinery is so designed that no single part shall be too heavy for transportation.

THE ATLAS ENGINE WORKS, of Indianapolis, Ind., has sold through its agency at Mackinac Island, Michigan, three large high-pressure Atlas water-tube boilers, to be installed in the new stamp-mill of the Michigan Copper Mining Co., at Keweenaw Bay, in the northern peninsula of Michigan. These boilers are for 200-lb. working pressure, they will superheat their own steam, without using a superheater, and are guaranteed to develop from 10 to 30° superheat, with the proper quality of coal and good firing.

PRICES in the electrical trade continue to show a distinct upward tendency in sympathy with the well-maintained advance which has taken place in the prices of all raw materials. Orders for future delivery can only be placed in many instances at a considerable advance over present market quotations. The GENERAL ELECTRIC COMPANY, in common with many other large manufacturing concerns, is announcing a general advance in prices of electrical apparatus and supplies. This will not unlikely be followed by further advances, if present market conditions continue.

Books Received.

PROBLEMS IN SURVEYING, Railroad Surveying, and Geodesy, by Howard Chapin Ives and Harold Ezra Hilts, both instructors in the University of Pennsylvania. It is a manual to be used in field courses of study. Published by John Wiley & Sons. Price \$1.50.

PETROLEUM AND ITS PRODUCTS, by Sir Boverton Redwood, deals with the whole subject of petroleum, its geographical distribution, and geological occurrence, also the physical and chemical properties of petroleum and ozokerite, together with a full description of natural gas, shale oil, and allied industries. Published by J. B. Lippincott Co., Philadelphia, Pa.; 2 Vol., price \$13.50.

THE STEEL SQUARE AS A CALCULATING MACHINE.—This little book describes in simple language a number of difficult problems in all branches of mechanics that may be solved by the aid of the common steel square without any calculation whatever. The explanations are full and clear, so that they are easily understood and put into practice. Published by the Industrial Publication Co., New York. Price 50 cents.

'Industrial Furnaces and Methods of Control,' will be welcomed by the managers of furnaces. There is a poverty of English literature on this important subject, which renders this admirable translation of Emilio Damour's work, by A. L. J. Queneau, the more welcome and valuable. It gives the results of many scientific experiments, as well as of practical experience. The value of the book is greatly increased by the numerous halftones, line drawings, and diagrammatic plates which accompany it. There are 21 chapters in the volume, each devoted to a particular branch of the broad subject, passing from one phase to another in rational succession. It deals with heat, and its generation; utilization of heat; types of furnaces; fuels, their analyses and efficiency; chimneys, and numerous useful tables. This valuable book will be sent by the MINING AND SCIENTIFIC PRESS upon receipt of price, \$4, postpaid. *The Engineering & Mining Journal*, Publishers, 505 Pearl St., New York.

Editorial.

ON ANOTHER PAGE Mr. John A. Reid makes a plea for the preservation of place names, such as embody the history of the country. In California particularly, where the Spanish names carry forward the traditions of an era now fast receding into the historic background, it is well to retain intact the old nomenclature.

EVERYONE KNOWS that Mr. Albert Ladd Colby possesses a vast amount of useful information, especially on nickel steel, but we were not prepared for the statement that his "search through the proceedings of scientific societies for the past eighty years" showed that someone was a little severe in his criticism. If Mr. Colby has been delving into the reference library of the profession for eighty years he must be a sage indeed, and we hope he will hasten to write his autobiography before it is too late—*absit omen*. All of which is merely intended to draw attention to the value of punctuation.

THE GEOLOGICAL SURVEY OF CANADA is being bothered by enquiries regarding the advisability of investing in the Amalgamated Coal Company of British Columbia, and while it cannot give such advice, it refers to the reports of Mr. R. W. Ells on the Nicola and Quilchena coal basins. It appears that the 17,000 acres of the alleged coal company are all situated in volcanic rocks, and that the claim to a large tonnage of valuable coal is without basis of fact.

IN THIS ISSUE we publish an article on the legendary mines of the desert region by Mr. W. H. Storms. The article is written in his best vein and is full of interest, together with a dash of humor—a most excellent seasoning. These legendary mines have caused loss of life and money in the fruitless search for fabulous veins of gold, but they have not been an unmixed evil, for the lure of them—like that of the fabled El Dorado, the Hesperides, and Ophir—has drawn strong energetic men into exploration of untraversed tracts of desert country and, in a way, prepared the way for the present blossoming of southwestern Nevada. 'Lost mines' are making their appearance in prospectuses and it is a wonder that they have not been used more by the predatory financier, for it is a fact that humankind has ever been fascinated by the picture of lost treasure, sunken galleons, and buried gold. The year now closing has seen the equipment of an expedition to find the loot of a pirate's nest, as disclosed by a chart made by a prisoner who escaped. But even in this there is, to a modern mind, less of fascination than in the story of a wandering prospector that loses his way, and dying of thirst, sees the fierce sun set behind forbidding ridges, alone in an aching desolation; then the slanting sunbeams strike an outcrop of quartz and as the light suffuses the white rock, he

sees that it is ribbed with gold. He breaks off some pieces, his courage is restored, he faces the unknown once more, and emerges at last—the wreck of a man—on the outskirts of civilization. He has been compelled to drop his specimens of golden quartz, for they were too heavy, so there is only his story and his privations to offer as evidence. And so forth. But truth is stranger than fiction, and the facts that appertain to the discoveries of mines in the Great West will put to shame the most lurid imagining of the literary artist. For example, the authentic tale—for is it not recorded in the chronicles of the U. S. Geological Survey—of the men whom Tabor grub-staked, who took with them a bottle of whisky—to be used medicinally—and having started up the hills behind Leadville, decided that the moment was propitious for the emptying of that bottle—so that they might not be burdened with the unnecessary weight of it. Having imbibed generously, it occurred to them that there, on the spot where they rested, was the place to dig a hole, for it looked a likely place for mineral—to a fuddled head. They dug and they struck it; it happened to be one of the few places where the Leadville ore measures came near grass roots; their haphazard hole became the Little Pittsburg mine. The moral being, not that you must use whisky in prospecting, but that you must dig.

Air Blasts.

On another page we give a part of Mr. C. R. Corning's scholarly translation of a most interesting paper on the cause of air blasts in the famous mines of Příbram, in Bohemia. Similar phenomena have been observed in India, in New South Wales, and in Michigan, although the conditions have differed in each locality. Chemical processes have been referred to in explaining this sudden rupturing of rock underground, and the analogy of the so-called Prince Rupert's drops—made by sudden cooling of drops of molten glass—has been used to illustrate the state of molecular strain, the sudden relief of which is supposed to cause the explosive shattering of the rock. But these theories have been largely put to one side as careful observations have been gathered in different parts of the world. At Příbram the explanation given is in accord with the generally accepted view that air blasts are traceable to unequal stresses caused by strata that are in a region undergoing pressure, and that the immediate cause is the disturbance of an unstable equilibrium by mining operations. In these celebrated mines the pressure of the overlying rock-mass is one factor, but a distinct stress parallel to the bedding planes of a synclinal fold, is another. Despite precautions, several men have been killed and now it is the custom in dangerous ground to use shields, made of planks firmly spiked together. It may be described as the intrusion of man into a geological position of extreme delicacy. The sudden shattering of the sandstone at Příbram into a number of fragments, with a noise as of a powder explosion, is duplicated at Hillgrove, in New South Wales, where there is a particular belt of silicified slate known as the 'kicking zone.' This slate is traversed by numerous joints, coated with films of cal-

cite. When tapped with a hammer the rock breaks suddenly into fragments. Where an arch of ground is left standing in the stopes, it is apt to exhibit extreme strain, pieces flying off with projectile violence and sometimes the whole mass explodes, with the noise of breaking crockery, so as to cause fatal accidents. But these occurrences do not happen in cross-cuts or in shafts, only in drifts that follow the gold vein, suggesting that it is the extra pressure consequent upon underground excavations that is the final factor in causing the rupture of the rock. In the gold mines of the Mysore, in India, the rock has been known to 'fly' and in this case the explosive shattering is not confined to one kind of rock; it has been noted not only in the hornblende schist and in trap dikes, but in the quartz veins that they enclose. It is stated that there is a well-marked jointing, suggestive of extreme pressure. In this instance also, it is conceded that the air blasts in the lode may be due to pressure of the walls following the removal of ore. Such undoubtedly is the case in the copper mines of the Lake Superior region. There air blasts have attained the dignity of 'earthquakes' and when several of them occurred last April, the daily papers gave them a kinship with the jar that so seriously disturbed San Francisco. But this, of course, was an error. The big copper mines that are most affected by air blasts have been stoped almost continuously in strike and dip for several thousand feet, and, the lodes dipping rather flatly, there is a great superincumbent mass of rock, the pressure of which increases as the mines are deepened. When the strain is too much for the pillars and arches left standing in the stopes, there is a sudden crushing of the rock, a collapse of the hanging wall, and the violent expulsion of a large volume of air, with reverberations and vibrations that extend throughout the mine and to the surface, where the houses and those that inhabit them go through an experience not unlike that of a small earthquake shock. In these lodes, with a dip of 37 to 50 degrees, there is a big overhang, a width of 8 to 20 feet of ore being stoped continuously, save for occasional pillars, until the pressure becomes excessive. If the ground would yield easily, or if soft headboards were used with the stulls so as to take up the pressure gradually, the suddenness—and with it the violence—of this settling of the ground would be decreased. The Quincy and the Atlantic mines are famous for their air blasts. The former has 62 levels, reaching to a depth of over a mile on the dip, with almost continuous stopes 3 to 20 feet wide, and almost as long as they are deep; the latter has been stoped for a uniform width of 15 feet to a depth of nearly 3,000 feet on a dip of 54° and for a length of over 4,000 feet. Successive air blasts in the early part of this year finally compelled the abandonment of mining at the Atlantic, the extra cost of repairs being too much for the small profit won from a lode that averaged less than one per cent native copper. Thus, in every case, we find that mechanical causes explain these mysterious rock explosions and that while nature is primarily responsible for the condition of unstable equilibrium, the immediate agent is man, who interferes with forces that are beyond his control.

By the Way.

In a recent address on 'The Technical School and the University,' Mr. William H. Burr, professor of civil engineering in Columbia University, said:

So closely are all forms of knowledge related in their fundamental elements that no one of them can attain to a state of real growth without carrying others with it. This elementary principle, which finds illustrations and the most conclusive proof in every field of educational experience, underlies the fundamental organization of the university, and it completely justifies the place of the technical school in the university plan.

The ramifications of every branch of science reach a great variety of human interests, many of which are directly affected by it, while others are more remotely touched. The full significance of every acquisition of knowledge can only be understood or even to a small degree appreciated by realizing the industrial activities or other real interests of the community which it affects. An isolated study of any one technical subject, or of any other subject, without regard to its relation to other branches of knowledge, would be excessively narrow in its results and probably as valueless as narrow, if indeed such a study be not unthinkable. The greater the number and scope of scientific or technical subjects brought within the range of instruction, the broader will be the whole amount of knowledge acquired, and the more complete and thorough will be the comprehension of any one of them. There is a limit to the number of subjects which can profitably be taken by any student in a course of proposed study, but there can be no question whatever that the instruction in any one subject will be enhanced in value in proportion to its breadth, or its reach into other and related or affiliated subjects.

The more complete the view of the field covered, the more satisfactory will be the student's work in it. In fact, it may be stated that the real study of any one part of the field of knowledge consists in acquiring information relating to its effect upon other fields into which it reaches. It is impossible to conceive of any subject of scientific study as an abstraction either from other subjects or from the material elements of experience.

The advantages gained by a technical school in a university environment are fundamental; they touch both its technical work and the general educational training which must precede the technical in any adequate course of study of a professional character. An engineering or other technical student pursuing his work in a university system finds himself in a stimulating atmosphere of study and investigation reaching far beyond the limits of his own field. He acquires largely by incidental or even unconscious absorption a broad cultivation by constant contact with active educational work, some of which is more or less affiliated with his and some not. This association is an inspiration to a broader and more enthusiastic view of his own work in itself as well as a material enhancement of value of that work by disclosing its relations to other fields of learning, all impossible to attain outside of the university. These conditions give his educational training qualities that not only strengthen them and widen his subsequent professional practice, but contribute most effectively to his intelligence and usefulness as an educated citizen.

More than this, the technical professions now demand of their members for the higher planes of successful practice the same general educational preparation for professional study as that required by the best law and medical schools. Without entering into a discussion as to the relative merits of the educational work done by the small college and by that forming a subordinate member of the university, it is sufficient to say that this

part of a well-rounded course of professional study harmonizes completely with the university system, and is in fact an essential element of it.

The university has long since lost the character, if it ever properly had it, of a place where abstractions of learning, separated from the things which only give them life, are to be dispensed after the manner of instruction to men who are never to deal with the affairs of life. It has come to be an intensely practical working agent. It is effective and worthy of support only in so far as it makes itself felt in the real life of the community. If it is to be a true and real centre of instruction it is imperative that it shall carry knowledge into every useful calling, governmental, corporate, or private. The time will soon come, if indeed it is not already reached, when it only can prepare men to administer and extend in a rational and moral way the great industrial activities which at the present time form the foundation of the material prosperity of the modern world.

The true student of the professional or technical school becomes heir to a comprehensive and clear understanding of his duties and responsibilities in his relations to his fellow men and to the community. Those duties and responsibilities present themselves to his trained mind in their real proportion. He is neither non-developed nor mal-developed in his judgment of affairs. His university training, especially in the technical school, has taught him accuracy and penetration in the analysis of any proposition confronting him, and that truth and knowledge must be sought with the directness of a plumb line. Science yields nothing but confusion to the shifty, devious, and dishonest inquirer. The fundamentals of morality are the very stepping stones to technical success or professional attainment.

The opportunities offered in the administration of public affairs and the great corporate interests of the present time, rapidly increasing in number and magnitude, create almost irresistible temptations to prostitute them to selfish gain. The realization that great power, or what has now come to be its full equivalent, great wealth, is a grave and delicate trust, to which selfish gratification in its infinite and seductive variety is abhorrent, comes most naturally and easily through sound knowledge 'the beginning of wisdom.'

The correct conception of his duties gives to the professional man such a deep and true sense of his responsibilities as to render him the safest administrator of those great interests whose sinister power has already threatened both the morals and the safety of the community. Selfish gratification is a temptation to which he may or may not yield, but his inheritance from the university translates wealth to be a means of accomplishing the highest means of life, and saves him from that narrow, common complacency of wealth which is the dry rot of character.

In this age of self-appointed erratic and dangerous regulators of society when an unreasoning and destructive discontent frequently prompts to crude measures whose real purpose is a blind upheaval of the existing order of things, the intelligence and the calm balance of the university man of affairs must be the corner stones of public safety. His trained mind taught to analyze and to test by the records of experience no less than by the precepts of science does not lose its poise before either the shallow plausibilities of the advocate of Utopia or the sinister deceptions of the revolutionary reformer or what has come to be nearly as bad, by the egoistic and blundering, although much-applauded strenuousness of the present time. It is not to be supposed for a moment that every subject of university training will issue from its halls the ideal well-rounded citizen, but judgment must be passed upon such matters in view of their resultant tendencies.

Special Correspondence.

London.

Cornish Mining.—More Flotations.—Irish Copper Mining.—Local Enthusiasm and a Banquet.—San Francisco del Oro.—Stratton's Independence.—Treatment of Low-Grade Ores.

The Cornish mining industry is described by a well-wisher as steadily progressive. One would like to see more proof of it at the tin 'ticketings,' as a variation in the list of the ten or a dozen old familiar names that crop up at every fortnightly sale for about the same tonnage more or less. We are promised that it is really "hoped to offer" a first parcel of black tin from South Crofty next week. Progress is still marked by the writing up of old mines for flotation. The Tresavean mine, in the once famous district of Gwennap, is being taken in hand, it is said, by a new company. The late Capt. Thomas Teague, at an outlay of about £1,000, succeeded in discovering its wealth. Under different companies the mine has divided among shareholders some £800,000. From the year 1814 to 1848 it returned the large quantity of 307,970 tons of copper ore, which realized £1,879,735. In 1833 £60,480 was divided among the holders of 96 shares. At this time the shares were negotiable at £2,700 each, £20 paid. The Killifreth 'sett' is another historical property enjoying the attention of "an influential group." The property is just south of the Great Busy mines, and north of the celebrated Gwennap, and is considered by local authorities as one of the best pieces of mineral ground in the district. It is probable that a large part, if not the whole, of the capital, will be subscribed privately. Sufficient work was done in the old mine when last worked to prove that the lodes approaching the cross-course gave every indication of yielding large quantities of mineral. Tin mining in Malay is also not without its admirers. The shares of the Lahat Mines, Ltd., have been put upon the market. This company, which has a capital of £120,000 in £1 shares, all issued, states that it has acquired, as a going concern, a group of tin mines of an area of about 172 acres, situate at Lahat, in the Malay Peninsula. The mines are said to have been worked for some years by Chinese tributers under a primitive and wasteful system, but have, it is now reported, produced regularly for some time past from 20 to 60 tons of the metal per month.

As a sequel to the formation of the new company and the provision by underwriters of £75,000 cash for working the Bonmahon copper mines, a large company of pressmen and engineers visited the company's properties lately at the invitation of the directors, and inspected the newly re-opened workings. The mines are situated in the village of Bonmahon, 17 miles from Waterford, and, though really not more than 14 hours distant from London, are somewhat "in the wilds." According to one of the numerous and enthusiastic accounts published for the information of the public that "deeply needs instruction" on the subject, every arrangement for the comfort and convenience of the guests had been made by the company and it seemed that every jaunting-car in the South of Ireland had been 'commandeered' for the occasion. Great interest was aroused in the neighborhood by the appearance of such an unwonted concourse of strangers, the peasantry turning out to do honor to the visitors, who, they believed, had come over expressly to restore a once-prosperous, but long-since decayed, industry of Ireland. After pleasantly occupying some hours in a "thorough inspection" of the properties, the company returned to Waterford, where, in the evening, a banquet was held, under the presidency of Sir James Power. The

chairman, in a very interesting speech, outlined the program of the syndicate that owns the Bonmahon mines, and expressed the belief that a great step forward was being taken in restoring to Ireland one of her former industries. It is now confidently asserted that the Company will begin to pay dividends in 1907.

According to news from India, the reports from the Mysore mine continue to be of a most satisfactory character. In the No. 1 winze below the 3,226-ft. level north of Ribblesdale's shaft the lode is 5 ft. wide, assaying 2 oz. 5 dwt. 7 gr. The No. 2 ends north and south of the above winze are also opening up good ground. The lode in the former is 5 ft. wide, assaying 2 oz. per ton, and in the latter it is 5 ft. wide, with an assay-value of just under 1 oz. 18 dwt. The new discovery in McTaggart's section continues to open up well.

Interest is being maintained in San Francisco del Oro, the shares of which have risen some 10s. in price during the fortnight's account just closed. In issuing the accounts for the year ended December 31 last, the directors state that sales of ore, rent, &c., have realized £47,591, while the net profit over all expenses is £25,880. Including the balance of profit brought forward, the total profits to be dealt with are £50,201. It has been necessary to put the whole of these profits back into the mines in the form of capital expenditure. The directors have written £25,022 off in respect of depreciation and development, leaving £25,179 to be carried forward. Within the past few weeks a considerable amount of further working capital has been subscribed in respect of part of the unissued shares, and sufficient capital has been thus provided to meet all expenditure up to the end of 1907, independent of any income from the sale of ore to the smelters. The ore reserves already actually developed amount to 280,000 tons of good ore averaging about 26 oz. silver, 11% lead, 25% zinc, and a little gold. The completion of the fourth level should add another 200,000 tons of ore to these reserves. It is expected that shipments will shortly be resumed as there are considerable reserves of shipping ore above the third level. A large proportion of the zinc values, which have hitherto been entirely lost, can now be profitably recovered, and when the process is settled it is intended to erect a plant capable of dealing with fully 200 tons per day. The directors having cabled the manager for confirmation of the reports that a water supply had been struck, and that a body of rich ore had been discovered, the following cablegram has been received. "Reports are true. Late development shows very considerable improvement. Assays of highly satisfactory character. Silver 1,620 grams (52 oz.); gold, 5 grams; lead, 23 per cent; zinc, 25 per cent."

The change in the management of Stratton's Independence, referred to in my correspondence of last week, is now confirmed by the directors' annual report for the twelve months to June 30 last. It states that the revenue account at the mine shows the sales of ore to have realized £256,726, of which £186,424 is on lessees' account, £70,302 being the total royalties and percentages of profits retained by the company, or 36.87%. Three dividends, each of 6d. per share, were paid, amounting to £75,000, the last distribution on April 10, 1906, bringing up the total of dividends paid since the incorporation to £979,173. After providing for these and sundry writings off, the balance on June 30 last was £25,090. Mr. George A. Schroter, in his report, says: "You must expect a steady decrease in production until such time as it is feasible to treat much lower grade ores. An examination of the Stratton mine proved the following: First, that there is 600,000 tons on the dumps of an average value of \$3.70 per ton. Second, that there is between 60,000 and 75,000 tons of broken material in the stopes, assaying about \$5 per ton, and which will probably cost between \$1 and

\$1.50 per ton to deliver to the surface. Third, that there are areas or zones on the different levels which probably will produce a large quantity of milling ore. The sampling showed the character of the material in these zones to be so spotted or irregular in values that it is impossible to judge its value without breaking large tonnages and putting the same through a mill. Experiments were made in a small way on samples of dump material, the results of which would seem to prove that previous estimates made on dump ores are very conservative, that is, a profit of \$1 per ton on dump material, assaying \$3 per ton—and should be exceeded in practice,” but he leaves it to the board to decide as to the erection of a low-grade ore mill without indicating whether in his opinion he considers such a step advisable. The manager, Mr. Charles Becker, seems more positive on this point, and urges that “something should be done” at once. In his opinion “when it comes to the milling of low-grade ores, tonnage of same will be found sufficient to keep a large plant running for many years.” The manager also mentions that as regards the freight and treatment on shipping ore, owing to the action of the American Smelting & Refining Co., the treatment costs averaged about \$1.25 per ton in excess of the preceding year. With regard to future earnings, Mr. Schroter considers that from a comparison of last year's results with those of the preceding year, with practically no amount of ore in sight, at the present time it is safe to say that the earnings will not be any larger than, or even as large as, the past year.

Leadville, Colorado.

General Lowering of the Water Level.—Large Orebody in the Humboldt.—The Resurrection to Resume.—Work in East Tennessee District.—George Campion Organizes Another Company.—The Helena Shipping Sulphide Ore.—A Sale at Ashcroft.

A significant feature in the local mining industry is the steady and regular lowering of the water line in the Leadville mining district proper, meaning in a general way the territory from Harrison avenue on the west to Adelaide Park on the east. Properties widely separated have experienced a gradual recession of their water-level, 150 to 250 ft. being an average. The facts are that many comparatively shallow mines have been freed entirely of their water, which but a few years since made them unprofitable for this reason alone. This wonderful change has been wrought by the persistent lifting of great volumes of water by the Midas Mining Co. down town and the Yak Co. and Iron-Silver to the east.—The Humboldt mine is sending to the smelter a large quantity of silicious and carbonate ores from a new shoot opened up during the past summer. From the present stage of development it appears to be the largest shoot of this character ever opened up in the Leadville district. The ore now presents a breast of nearly 25 ft. This property has also been favored by complete disappearance of water and as a result shipments will be resumed from a large body of sulphide ore formerly opened up, but abandoned on account of the flood of water. The manager states that the water's disappearance followed the starting of pumps on the Tucson, about half a mile to the south.

Among the big producers, the Resurrection will be the largest to resume operations before the close of the year. The property is now being put in shape by B. I. Groves, the manager, and connections are to be made with the Yak adit; but as the latter is still over 4,000 ft. distant, it will require several months to make connections. An electric pumping plant is to be installed to meet the present requirements and when unwatered a drift will be driven south from the lowest level to meet the Yak adit coming from the opposite direction. This property for-

merly shipped, during a long period of activity, more than 200 tons daily, and just before being abandoned, energetic development was being pushed on the 1,100-ft. level. There are extensive bodies of ore of low-grade that with the advent of favorable smelting charges and cheaper transportation will make this property a dividend payer. —The northern shaft of the Western Mining Co. is silent as a result of an injunction reported to have been issued by Judge Lewis of the Federal Court, granting a permanent injunction against the Northern people from further operations. A costly and tedious litigation has hampered this property in the past, and as yet there are no indications that the end is in sight.

Among the new properties to begin operations in the East Tennessee district is the Martye Bird, with F. E. Baker as superintendent. The company controls 40 acres south of the Jennie June mine, and a shaft is being sunk, from which a drift will be run to cut the Jennie June vein. Since connections were made with the Yak adit some weeks ago, the Louisville has been developing an unusually valuable shoot of zinc ore and is now shipping

A Part of Colorado.

a large tonnage.—George Campion has consummated a deal by which a group of claims on Long and Derry hills, six miles southeast of Leadville, will soon be developed on an extensive scale. The property will embrace about 160 acres, upon which Mr. Campion has obtained a long lease, and the new hoisting plant has been completed at a cost of \$25,000. Cottages are being built on the ground to accommodate the workmen with families, the idea being to obviate the usual shifting of men which would otherwise occur in the working force. The present working force amounts to 20 men, and when the shaft reaches a reasonable depth a much larger force will be added, to extend drifts now projected. Opinion is current that Mr. Campion expects to cut the big ore-shoot that he is working on the famous Reindeer. The new company is styled the Musk Ox Mining Co., and is one of the strongest organizations in the Leadville district. As is usual in the development of Leadville's mineral resources, the enterprise was instigated, and will be carried to completion, by local capitalists.—The Helena is shipping a good grade of lead sulphide from the 300-ft. level. It is intended to unwater the workings to the bottom of the 600-ft. shaft. Since the Ollie Reed went into the hands of the Yak company a few months ago, the latter has kept up work, presumably on the higher levels where the former owners at one time shipped considerable ore of good grade; diamond drilling

is, being employed to prospect the lower contact.— Joel Smith has consummated a sale on the Tom O'Shanter group of mines at Ashcroft to a syndicate incorporated as the Tom O'Shanter & Montezuma Mining Co. This property has been made famous by both its production and litigation, the latter extending over twelve years in the various courts of Colorado.

Cripple Creek, Colorado.

Strikes in the Mountain Beauty and Trilby.—Prosperous Lessees.— The Gregory to Be Worked.—Good Ore From Guyot Hill Mines.—New Rates of Ore Treatment.—A Dividend.—The Drainage Adit.

A good strike has recently been made on the Mountain Beauty Mining Co.'s property on Bull hill. John Hodges and F. R. Marsh are operating a block of ground, from the surface to the 600-ft. level under lease. A fair sized vein has been encountered in this lower level, on which active development is being done, and the lessees hope to open up as good an orebody as they are now working on the Little Clara claim of the Work Co.'s property. This new strike has caused the stock of the Mountain Beauty to rise considerably during the last few weeks. On another part of the same property, Sellers and Blanchard have discovered a new vein at a depth of 280 ft., and assays of \$30 per ton have been obtained.—The Pittsburgh and Philadelphia capitalists who lately bought the Trilby mine on Bull hill from the Moose Gold Mining Co. have incorporated under the title of the Trilby Mines Co. The capitalization is 1,000,000 shares at a par value of \$1. James T. Stewart, one of the incorporators, will be in charge of the company's interests in the district. The price paid for the Trilby property is said to be \$125,000. A discovery of ore was made by the new owners a few days ago on the eleventh level of this property; in clearing away some waste that had been left on this level a vein estimated to be six feet wide was found. It is thought that the vein was covered up intentionally by the Trilby Leasing Co., which operated this mine two years ago, the discovery being made near the termination of their lease. Indications of the find were obliterated in hopes of the lease being renewed, but an extension was refused by the Moose Company.

Lessees on the Free Coinage mine, situated at Altman, are shipping ore of fair grade. J. O. Carper, operating through the Pinto-Bison shaft, has made a shipment during the last few days, returns of which are not yet to hand.—The first clean-up is shortly to be made by the Isabella cyanide mill and good results are anticipated. Seventy-five tons of dump ore are being treated per day.

The old Hayden workings on the Gregory claim of the Elkton Consolidated Gold M. Co. have been leased to Smith & Johnson. Explorations to discover the continuation of the rich orebody formerly worked by L. Hayden, will be undertaken. After yielding around \$250,000 profit to this lessee the orebody pinched out, and the property lay idle for about a year.—Two cars of ore have been shipped during the last few days from Guyot hill properties. One car was from the Aileen and the other from the Chicken Hawk mine. Returns of between \$30 and \$40 per ton are expected in each case. The Colorado State Investment Co. is operating the Aileen mine under the management of John Sharpe, and the Chicken Hawk by the Columbia Mining & Development Co., Charles Walden being manager.—The South Burns of the Acacia Co. on Bull hill, operated by the Standard Leasing Co., is shipping ore that gives returns a little better than an ounce. The ore is obtained at a depth of 800 ft.—The treatment rates on ore from the Cripple Creek district have been reduced by the smelter trust. The

reason for this is given out as due to the demand for ore by the United States Reduction & Refining Co. owing to the completion of the Golden Cycle mill, which will handle the outputs of the Golden Cycle, Findley, and other properties. The new rates are lower than those of the Golden Cycle, and whether the latter mill will meet this reduction remains to be seen. The change is as follows:

	Elkton.	Golden Cycle.	Old open rate.	New open rate.
Up to \$10 per ton.....	\$5.75	\$.....	\$6.25	\$.....
\$10 to \$15.....	6.50	5.75	7.50	5.50
15 to 20.....	6.75	6.50	8.00	6.00
20 to 25.....	7.25	7.50	9.00	6.25
25 to 30.....	7.50	7.75	9.25	6.75
30 to 40.....	8.50	8.75	10.25	7.50
40 to 60.....	9.25	9.50	11.00	8.50
60 to 100.....	9.75	10.00	11.50	9.00

From the above table it is seen that there will be a reduction in cost of treatment between \$2 and \$3 per ton, which will materially aid in the marketing at a profit of the low-grade ores of the camp.

A dividend of \$30,000 or two cents per share has been declared by the Work Mining & Milling Co. During the last eight months ending November 30, a profit of \$79,473 has been made—about \$10,000 per month. Dividends amounting to \$60,000 have been paid, leaving \$19,473 in addition to the balance on hand April 1, of \$13,143.—A strike has been made on the Four Brothers claim of the Agnes Co. situated on the east slope of Beacon hill. Driving has been going on at a depth of 250 ft. in an easterly direction to catch a vein opened up on the 150-ft. level above. The vein is four feet wide, averaging around \$40 per ton, while a 10-in. streak shows values of several hundred dollars per ton. The Wabash Leasing Co. is operating this property, several of the county officials being interested.

A meeting was held at Colorado Springs on December 18 of Cripple Creek mine owners, when nearly \$1,000,000 was pledged for the driving of the big drainage tunnel. A resolution was passed calling for the work to be commenced at the earliest possible date, which will be about January 15. As soon as the project assumes definite proportions, the smelters, mills, and railroads will come in and help the undertaking. In view of the commencement of operations, the stocks of the properties that lie in the immediate line of the tunnel have strengthened considerably.

Salt Lake City, Utah.

Mineral Output of Utah.—Dividends Paid During 1906.—Smelter Smoke Troubles.—Removing Operations.—Electrical Plants.—Railroad to Pioche.—Sundry News.

According to authentic figures recently released (the month of December estimated) the metals produced in the mines, smelters, and mills of the State during the year aggregated the sum of \$38,042,383, the classification being as follows:

470,976 oz. gold at \$20.67 per oz., \$9,735,082; 15,981,315 oz. silver at 66.585 cents per oz., \$10,629,517; 67,303,376 lb. copper at 18.95 cents per lb., \$12,744,988; 115,018,811 lb. of lead at \$5.635 per 100 lb., \$4,480,310; 6,472,734 lb. zinc at \$6.153 per 100 lb., \$398,267; 1,276 flasks of quicksilver at \$42.50 per flask, \$54,187. In some instances it has been impossible to segregate ores coming from other States, but an allowance for this of \$5,000,000 has been made, leaving a net result therefore of over \$33,000,000 as representing the value of the gold, silver, lead, copper, zinc, and quicksilver ores extracted from the mines of Utah alone during the year 1906.

The dividends paid during the present year aggregated a total of \$5,148,044 and the mines credited with these

payments, together with the respective amounts were: Beck Tunnel Consolidated, \$305,000; Bingham-New Haven, \$22,600; Bullion Beck & Champion, \$40,000; Carisa, \$30,000; Consolidated Mercur, \$100,000; Daly West, \$432,000; Gemini, \$200,000; Grand Central, \$172,000; Horn Silver, \$80,000; Mammoth, \$140,000; Mountain View, \$12,554; Petro, \$32,000; Sacramento, \$40,000; Silver King, \$800,000; Swansea, \$18,000, Utah (Fish Springs) \$34,000; Utah Consolidated, \$1,350,000; Uncle Sam Consolidated, \$50,000; United States, \$1,099,907; Victoria, \$125,000; West Mountain Placer, \$2,483; Yankee Consolidated, \$42,500. The Utah Consolidated Mining Co. has posted a regular dividend of \$2.50 per share and an extra dividend of 50 cents per share, payable in January. The Daly Judge of Park City has posted its initial quarterly dividend of 37½c. per share, or \$112,500 for payment on January 12.

The Utah Consolidated Mining Co. has decided to abandon its smelter near Murray, south of Salt Lake City, as a result of the smelter smoke troubles. A new

Utah.

plant will be built, outside of the agricultural districts of the Salt Lake valley, at a cost of about \$1,000,000. It is also the intention of the company to engage in the treatment of custom ore. The site of the proposed smelter has not been settled, five sites are under consideration. The plant to be abandoned is treating between 800 and 900 tons per day and began in 1899 with a total capacity for the treatment of 200 tons per day; since it went into operation 1,500,000 tons of ore have undergone treatment in its furnaces, from which has been won about 90,000,000 lb. copper. R. H. Channing, Jr., who has been manager of the company since its organization in 1899, has resigned to accept the presidency of the Cerro de Pasco Mining Co. and the Cerro de Pasco Railway Co. in Peru, the same to take effect in January. His successor has not been named.

The Consolidated Mercur will not report the usual production of gold this month owing to a shortage of fuel, which has compelled a shut-down of the roasting furnaces in its milling plant. Other mines have been affected in the same manner, but none so seriously as the Mercur.

—The management of the Columbus Consolidated at Alta has installed an electric pump capable of raising 400 gal. per min. from the 300-ft. level below the adit.—

The Little Chief mine in the Tintic district is being operated with its new hoist, and will soon be producing again.—The Boston Consolidated Mining Co. has awarded the electrical contract for its Garfield mill, which is to have a capacity of 3,000 tons of ore per day, to L. M. Cargo, the local representative of the Westinghouse Electric & Manufacturing Co. It calls for the entire electrical equipment of the plant and the payment therefor of about \$50,000.

Ore shipments have recommenced from the Last Chance mine at Bingham; this mine is operated under the control of the Nevada Utah Mines & Smelters Corporation.

—A controlling interest in the Ohio-Kentucky Mining Co., at Pioche, Nevada, has been acquired by Samuel Newhouse, who has been elected president of that corporation. J. Ross Clark, vice-president of the San Pedro, Los Angeles & Salt Lake Railroad has made the statement that the contract for the grading of the proposed branch line from Caliente to Pioche will be awarded in a few days and that the laying of track will begin as soon as it is possible to get ties. The road will be about 30 miles long.—The Majestic Copper company, operating in Beaver county, is shipping a carload of copper ore daily from the Old Hickory and a car per week from the O. K. mine.—The Cedar Mining Co. has struck some high-grade silver ore in its shaft at a depth of 275 feet.

Butte, Montana.

Number of Men Employed.—Output of Ore and Contents.—Rich Ore in Alliance.—Operations of Amazon-Butte.—North Butte.—Explorations by Butte & Bacorn.—Final Payment on the Ophir.—New Machinery.—Recent Incorporations.

The average number of men employed in the Butte mines is: Amalgamated Co., 6,600; North Butte, 500; Butte Coalition, 1,400; Original, 1,150; Pittsburgh & Montana, 375; others, 1,620. Total, 11,705. The daily payroll for miners and surface men prior to November 15, the date of the raise in wages, was \$40,965. The monthly payroll prior to that time was \$1,228,955. The monthly payroll since November 15 averages \$1,316,735.—The estimated tons of ore mined by the various companies during the year were: Amalgamated, 4,000,000; Coalition, 390,000; United Copper, 90,000; La France, 47,450; East Butte, 72,000; miscellaneous, 328,000. Total tons, 5,715,850.

Estimates of copper, silver, and gold production of the Butte district, during the year now ending, have been made as follows:

Company.	Copper, lb.	Silver, oz.	Gold, oz.
Amalgamated	278,000,000	7,623,470	45,134
Butte Coalition.....	24,000,000	940,000	1,000
United Copper.....	7,500,000	250,000	1,000
Original	116,000,000	1,000,000	1,000
La France Copper	4,745,000	800,000	1,350
Pittsburgh & Montana.....	485,000	850,000	900
North Butte.....	40,000,000	2,000,000	1,000
Miscellaneous	10,000,000	2,000,000	1,100
Total.....	380,730,000	15,463,470	50,384

The Alliance Mining Co. has begun making shipments from the rich vein of copper it struck at a depth of 200 ft. recently. The first lot of 60 tons yielded about 11% copper, some of it assaying as high as 50%. The company expects to be able to ship 40 to 50 tons daily in a short time. Driving is in progress both east and west on the vein, which is eight feet wide, four feet of it being first class. The ore also assays well in silver, the average being about 7 oz. per ton, with \$2 in gold, making the gross value of the ore about \$55 per ton. Only Butte men are in the Alliance Co., and they own all the stock. The Alliance has 1,300 ft. of the vein, although there is a short piece of ground within that distance owned by

outside interests. The Farrell Copper Co. also owns a good bit of territory on the same vein and is developing it through the Alliance shaft, which was sunk jointly by the two companies. There is some talk about a consolidation of the two companies, but so far nothing definite has been done. The Farrell has several known veins within its boundaries. The Alliance vein has been traced for a distance of more than a mile, through the ground of the Ophir, owned by the Butte Central & Boston Copper corporation, and east through the Alliance and Farrell ground, and through a big tract of ground owned by the East Butte Copper Mining Co., far south of any of its present mines and workings, and in ground purchased by that company some time ago, to be used for the operation of a precipitating plant on the old Parrot smelter tailing, which covers that ground.

None of the new mining companies organized in Butte during the past year has made better progress than the Amazon-Butte Co., which was organized only two months ago and has erected a number of permanent buildings, a large and complete plant of machinery now running perfectly, and has a double-compartment shaft down 100 ft. The company owns the Amazon, West Altona, and Gagnor lode claims, all patented many years ago, situated about a quarter of a mile south of Bullwhacker, and covering for more than 1,000 ft. the main north and south fault-vein that is so prominent in the Bullwhacker. The Amazon group also adjoins the properties of the Ida-Montana Co. on the west and covers 1,600 ft. of the main Ida east and west vein, from which that company has extracted excellent sulphide ore at a depth of only 110 ft. The Amazon ground also contains four other distinct veins. The location of the shaft was selected as being some distance from any vein, yet it dropped down upon an unknown vein 12 ft. wide at a depth of 50 ft., from which highly mineralized vein-matter and some ore has been taken. The shaft should reach a depth of 500 ft. by May, when cross-cuts will be started, while sinking of the shaft progresses to a depth of 1,000 or 1,200 ft. A number of lessees are working in Amazon ground on the Bullwhacker fault-vein and are opening another big deposit of silicate and carbonate ores, almost identical with that found in the Bullwhacker, and at a depth of 60 ft. they have found several bunches and streaks of copper glance. The discovery of sulphide ore at a slight depth in conjunction with the large deposits of copper ore in the fault-vein, is said to indicate the proximity of larger and richer bodies of sulphide ore than have heretofore been discovered in that locality. E. H. Wilson, mining engineer for F. A. Heinze, and W. Spencer Hutchinson of New York, have examined the property and are outspoken in their high opinion of the showing made with so little development. The present company is merely a co-operate enterprise of several prominent Butte men that owned the claims, and there was not a share of promoter's stock allowed to anyone. The mining operations are managed by John Hewett, who was for many years superintendent of the Gagnon mine, owned by the Amalgamated Company.

The North Butte Co., in driving a cross-cut north from the 1,600-ft. level of the Jessie mine to reach the Berlin claim, has cut into another big vein in the Jessie ground. It is claimed to be some 20 ft. wide, and that nearly all of it is first-class ore. It is uncertain where the vein apexes, whether in the northern part of the Jessie or in the Gem, a small fractional claim purchased not long ago by the company from J. A. Murray and others. The North Butte now has four large veins—the Speculator, Edith May, Jessie, and the new one. The company expects to find another big vein in the Berlin ground, but that will not be reached within another

year. It is possible, however, if the North Butte's phenomenal luck holds out, that three or four other veins may be cut before the Berlin is reached.—The vein being opened in the combination mine by the Reins Copper Co. is growing larger, and is now carrying commercial ore for a width of 10 ft. The vein has been opened both on the 900 and 1,000-ft. levels, and a considerable quantity of ore is being hoisted. It is likely that another cross-cut will soon be started from the 1,200-ft. level.

The Butte & Bacorn Co.'s north cross-cut from the Calumet shaft at a depth of 500 ft. passed through a barren vein 17 ft. wide. The only values it contains at that depth are 5 oz. silver per ton, and about 1% copper. The vein is dry, indicating that the water-level has not been reached and that the minerals have been leached out to that depth. They will probably be found deeper in the vein, in the form of glance and bonanza ore. The barrenness of the vein does not surprise the management. At the 700-ft. level the Edith May vein of the North Butte Co. was absolutely barren, but at the 1,200 and 1,600 levels it was tremendously rich. There is no working on the Edith May vein between the 700 and 1,200-ft. levels, and it has therefore not yet been ascertained at what point the mineral deposits begin. It is probable that the Butte & Bacorn will not run another cross-cut until the Calumet shaft reaches a depth of at least 1,000 ft. The Belinda shaft, being sunk a short distance north of the Calumet, has reached a depth of 600 ft. It is the opinion of everyone familiar with the Butte & Bacorn ground that copper ore must exist in commercial quality within a depth of 1,000 feet.

The final payment on the purchase of the Ophir mine has been made by the Butte Central & Boston Copper Corporation, which took over the property on July 1, after an examination and favorable report made by several engineers sent to Butte by Freeman I. Davison and his associates of Boston. At that time the shaft was less than 300 ft. deep, and it has been sunk to the 500-ft. point, where an 800-gal. pump has been placed. In all the levels, four in number, fine bodies of silver ore have been opened, some of it showing good values in copper. The cross-cut on the 500 has disclosed 18 ft. of ore in place. Besides carrying high values in silver and gold, this ore shows copper glance and sulphides, so as to assay as high as 7% copper. Although the ore occurs in quantity, no shipments will be made until the new surface plant, now being installed, is ready for operation—in about 30 days, at which time all leases on the property will have expired. It is said that shipments of ore will then begin on a large scale, at least 200 tons per day. The shaft will be sunk at the same time and will be continued to a depth of 2,000 ft., with cross-cuts at every 200 ft. The new company has acquired additional property since it purchased the Ophir, and negotiations are under way for more. The latest acquisition is the Boyer mine, a small property on East Park St. in the city, on which there is a shaft 215 ft. deep, and from which some ore has been taken.—The North Butte Mountain Copper Co., which has a locator's rights to mineral ground in the Butte & Bacorn section of the district, announces that it will begin work soon. The company is capitalized for \$5,000,000 in 1,000,000 shares.

The Golden Sunrise Mining Co. has been incorporated by Kansas and South Dakota men to operate in the Butte district. It is capitalized for \$1,000,000 with shares at \$1 each. The directors of the company are J. L. Penny, A. H. Shaffer, J. E. Shaffer, and I. Brubaker of Topeka; L. L. Stephens, F. A. Stephens, and B. J. Binford of Pierre, S. D.—The new hoisting engine on the Greenleaf, owned by the Boston & Montana Co. has been fin-

ished and sinking has been resumed.—The new machinery installed on the property of the Colusa-Leonard Extension Co. is working nicely and good progress is being made in sinking.

Toronto, Canada.

Cobalt News.—Rich Ore in the Government Mine.—Prospectors Still Arriving.—Sturgeon Lake.—Treatment of Cobalt Ores.—Oil in Ontario.—Search for It Farther West.

W. G. Miller has returned from the Gillies Limit, Cobalt, and expresses satisfaction as to the discovery made in the vein, which was found in driving on the 70-ft. level at about 18 ft. from the shaft. The wall of the vein is being laid bare, indicating a solid orebody extending to the surface. A rich sample of the ore from this vein has been received by the Provincial Bureau of Mines.—Henry G. Adler has been appointed general manager of the Foster mine at Cobalt. He has had experience in South Africa and was for three months in charge of the University mine.—At the Trethewey mine a new vein has been discovered 50 ft. below the surface. It is only two inches wide, but carries very high-grade ore. About 90 men are at work. No. 1 shaft is down 120 ft., and driving has been done at the 50-ft. and the 100-ft. levels. The east drift on the 50-ft. level is 160 ft. long, and to the west it extends 60 ft. At the 50-ft. level a cross-cut has been started to encounter two veins found on the surface about 60 ft. apart. Two 80-h.p. boilers, a duplex compressor, hoist, and dynamos have been installed. Frank C. Loring has resigned his position as general manager of the company, but will remain in their service as consulting engineer.—The United Cobalt Co., which recently acquired several Cobalt properties, has a gang at work under Algernon Del Mar, a mining engineer from California, as superintendent. Shafts will be sunk and energetic development proceeded with.—The shaft on the main vein at the O'Brien mines is now down 300 ft. and active prospecting is being done on the southeast part of the property.—About 12 men are at work on the Gamey property belonging to Gamey & Wright, north of the Buffalo mine. A small calcite vein followed down 24 ft. has widened; it shows cobalt and niccolite.—At the Green-Meehan, large deposits of silver ore running as high as 4,000 oz. per ton are exposed on vein No. 1. It is stated that the output on December 19 and 20 amounted in value to \$25,000.—S. Price, the Mining Commissioner, arrived here on Wednesday from Cobalt. He reports that notwithstanding the wintry weather and the depth of snow on the ground, prospectors are still arriving and that six or eight new claims are recorded every day in the Haileybury office.

Charles Giffard, a Western miner, is developing, for a company whose name does not appear, a 20-acre property adjoining the Nova Scotia, Nipissing, and O'Brien properties. He has done about 1,000 ft. of trenching and has disclosed nine veins, one of which is a continuation of the Nova Scotia vein. Two shafts are going down, one of which is sunk 20 ft. and the other 24 ft. A plant comprising two steam-hoists, a six-drill compressor, and two 60-h.p. boilers has been ordered from the Rand Jenckes Co.—A. McEwen, manager of the Sturgeon Lake gold mine, in northwestern Ontario, has arrived at Port Arthur with gold bars of the value of \$8,000, the result of a six-weeks' clean-up. The concentrate will be of about equal value.

Experiments have for some time been carried on under the direction of Wills & Co., Toronto, in the treatment of Cobalt ores. They claim to have solved the problem satisfactorily, and are having a model plant constructed here for the carrying out of their process, which it is stated will be equally available for the treatment of British

Columbia gold quartz—rendering it profitable to reduce quartz ore assaying as low as \$5 per ton. The plant is operated on the principle of pneumatic concentration and employs no water. There are six inclined cylinders through each of which a shaft passes, and attached to the shafts are brushes revolving by means of level gears. The material, introduced automatically from bins above, is kept in rotation by the brushes, and the mineral content being heavier than the refuse, falls into the receptacle of the cylinder. A current of air introduced by a suction-fan at the upper end of the cylinder, carries away the gangue or tailing, which is forced up the cylinder and falls into a chamber, from which it is dropped by an automatic valve. The metallic contents of the ore, being too heavy for the air current to carry, work down against the air, and are released at the lower end of the cylinder. The air current can be closely regulated. The material is carefully sized, each size being fed to a separate cylinder. The process is regarded as being especially valuable in the treatment of low-grade ores at a distance from smelters. Some \$30,000 has already been spent in experimenting on the process.

There is much excitement over a new strike of oil in Romney township, Kent county, Ontario, in what is known as the Tilbury oilfield. The well is situated on the farm of J. A. Tremblay, about six miles south of the scene of active operations. The strike occurred on December 19 and oil gushed out in such profusion that at least 1,000 bbl. escaped. The well is only 300 ft. deep. Oil rights on M. Campbell's farm, Tilbury East, have been sold by the Campbell Oil Co., of Detroit, to A. D. Adkin, Spencerville, Ohio, and C. M. Vanburen, of Bolivar, New York, for \$56,000.—Eugene Coste, of Toronto, who has traveled extensively through the Canadian West during the past season in connection with the development of the oil resources of that region, states that so far no oil in any quantity has been struck. The Alberta Oil Co. has a well down 1,585 ft. at Pincher Creek, south of the North Kootenay pass, and has found a little oil. They will sink to a further depth. Mr. Coste is acting as engineer for the Canadian Pacific Railway, which has gone down 800 ft. and got a showing of gas. They will sink 2,000 ft. further if necessary in the hope of obtaining oil to use as fuel for their locomotives. The company has another well at Langham 1,000 ft. down, and will sink to 1,700 ft. Small results have been obtained by the Rocky Mountain Development Co. and the Western Oil & Coal Consolidated Co., operating in southern Alberta. Mr. Coste thinks that drilling operations have not so far been conducted on a sufficiently extensive scale to determine whether oil exists in paying quantities.

The mining rights to the bed of Cobalt lake, covering an area of 46 acres, recently advertised for sale by tender, have been sold by the Provincial Government for \$1,085,000 cash. The purchasers are a syndicate composed of several hundred subscribers, contributing not less than \$1,000 each, the principal promoters being Pellatt & Pellatt, and Britton Osler, of Toronto; Thomas Birkett, Geo. F. Henderson, and D. B. Rochester, of Ottawa, and Raymond Mancha, of Detroit. Five tenders in all were received, but two of them were not accompanied with the requisite cash deposit. There will be no royalty required on the output. Kerr lake, offered for sale at the same time, was not disposed of, as the highest tender was only \$51,500, which was not considered good enough. A tender from parties represented by Miller, Ferguson & Hunter, and T. A. Beament, of Ottawa, for the mining rights of about 14 miles on the right of way of the Temiskaming & Northern Ontario railway, subject to a 25% royalty on the output, for \$38,100 cash, was also accepted.

Mining Summary.

ALASKA.

The report circulated in Seattle that the Treadwell mines will close down on account of a shortage of coal is denied by the management. While the fuel situation is admittedly serious, the weather is moderating and a plentiful supply of water is anticipated. Robert A. Kinzie, the manager, in a late interview at Seattle, stated that while he had found it impossible to obtain coal anywhere in the United States, a plentiful supply had been ordered and was now on the way from Australia. Dispatches announce the arrival of the steamer Farallon at the Treadwell docks with 500 tons, and more boats on the way. A large oil-burning plant has already been installed, and will be in operation early in January. With ample water and a small amount of coal the mine can be kept running until oil supplants coal as fuel.

ARIZONA.

COCHISE COUNTY.

Following the discovery of orebodies in the Denn-Arizona, comes the news of a similar strike in the main workings of the Empire State, a property lying on the outskirts of the Warren district. About two weeks ago good ore was encountered while driving on the lode in the main shaft; since then the drift has advanced entirely in ore. The vein has a general trend from northeast to southwest, and has been cut by an adit 443 ft. long. As soon as this vein was encountered, a drift was driven which has now run 100 ft. in a southeasterly direction on the lode. A sample of 200 lb. has been sent to the smelter at El Paso. Hitherto the ore has carried values in gold and silver only, but during last week copper in the form of bornite and malachite has been showing strongly. A cross-cut will be started at once to determine the size of the orebody.

PINAL COUNTY.

The Silver Queen, a gold and silver proposition in the Superior district, has encountered a vein of carbonate ore in driving the old drift on the 300-ft. level. This ore assays 18% copper, and carries a large percentage of iron. There are about four feet of this ore in the face of the drift. Between this orebody and the quartzite, a large seam of copper glance was discovered that assayed 91 oz. silver and 58% copper. In a raise from the same level another vein was struck that carried 31 oz. silver and 46% copper. This vein is to be opened up as fast as practicable, and a winze is being sunk from the 300-ft. level. The 400-ft. level has also been re-opened and put into good shape, and here a good body of ore has been found assaying 17 to 28% copper. The company is now in a position to commence regular shipments to the Humboldt smelter, if teams can be secured to haul the ore to the railroad at Florence.—A carload of ore shipped recently from the Eureka group of copper mines situated at the Summit, 20 miles east of Florence, netted \$800 at the smelter. The main shaft is now down 158 ft., and a cross-cut back to the vein from the bottom of this shaft reveals a body of ore seven feet wide. On the hanging wall is a two-foot streak of shipping ore, and the assay average of the ore across the whole seven feet is about 7% copper. Two other lenses of pay-ore, dipping east in the vein, have been opened. This ore carries copper, gold, and silver.

GILA COUNTY.

(Special Correspondence).—Eastern people, as yet unknown, this week bonded three groups of 31 claims located five miles northwest of the city and a large force of men is at work on initial development work. The amounts to be paid for the claims aggregate \$300,000, final payment to be made in 18 months. The deal was consummated through F. J. Elliott and F. C. Alsdorf, the latter being retained as general manager for the purchasers.—On Saturday the Globe Consolidated struck a five-foot vein of sulphide ore in a new cross-cut on the 400-ft. level of the Mallory shaft. The management expects to begin shipments to the Old Dominion smelter within a few weeks.—The railroad of the Arizona Commercial Copper Co. is rapidly nearing completion. The road will connect the Blackhawk and Copper

Hill mines of the company with the road running to the Old Dominion smelter, and heavy ore shipments will begin as soon as the road is completed. The company will also ship carbonates from its open-cuts to smelters at Douglas, Cananea, and Clifton. This is said to make the finest converter lining in the Southwest and is in considerable demand by the smelters.—Tucson capital has invested in Globe district, Mose Drachman of that city and associates having closed a deal for three claims and a 160-acre ranch within a short distance of the new Mitchell smelter site. The consideration was \$100,000. It is believed that the ranch will be converted into a townsite. It is located three miles from Globe and within easy walking distance from the new smelter. Construction of the extension of the Gila Valley railroad to the smelter site will begin the latter part of this week.—The fuel situation here is much better than in any camp in the Southwest, judging from reports from Bisbee, Douglas, and Cananea, at which places the oil and coal shortages has threatened to close mines and smelters. There is plenty of both kinds of fuel here to run indefinitely.—Reports from the Queen mine at Superior state that during the last week a 2½-ft. vein of solid glance has been encountered and a car of ore assaying 60% copper and 100 oz. silver will be shipped to the smelter at Humboldt, Ariz. This mine is an old silver mine that was abandoned a number of years ago and it was recently purchased by a number of Globe business men, who are now operating it.—The new 100-ton concentrator of the Pinto Creek Mining Co. will be placed in commission soon after the first of the year, the work of construction and installation of machinery having been completed. The 75-ton mill at the Inspiration mine will be started at about the same time.

Globe, Dec. 25.

(Special Correspondence).—Operations at the Dominion smelter at Globe are continuing satisfactorily. Until the last week or two the smelter was handicapped by a lack of sulphide ore, but recently shipments of sulphide began from Cananea and Nacozari, in Mexico. The shipments will continue, enabling the company to resume smelting with four furnaces without interruption until the end of the month, so that there will be no reduction of output. Trouble has been experienced in securing an adequate supply of fuel oil, owing to a tank-car famine, and as there is no prospect of relief, the company has decided to use coal, which will be supplied by the Dawson mines in New Mexico, owned by the Phelps-Dodge Co. Shipments from the Continental mines now average 65 tons daily, and the development of sulphides in the lower levels of the Globe, the principal mine of the Old Dominion, is satisfactory. The west drifts on the thirteenth and fourteenth levels are both in good concentrating sulphide ore.—Another big mining transaction has just taken place, consisting in the sale of the Chapparal group of 13 claims northwest of Gibson, and the Halliday group of four claims lying between Gibson and the Chapparal group. The company that is to operate the Chapparal is to be known as the Union Copper Co.—The Pennsylvania Co. has been re-organized under the name of the Pennsylvania, Cananea & Globe Co., and has taken over control of the properties formerly operated by the Five Points Mining Co. at Globe; these will be worked in connection with the South Cananea properties of the old corporation. Preparations are complete for extensive development at the South Cananea, where the heavy machinery necessary for further sinking is now in place. George Mitchell, who was superintendent of the old company, will serve in like capacity for the P. C. & G.—Globe capitalists have formed a corporation to develop and operate 12 claims situated on the southeastern slope of Pinal Mtn., six miles south of Globe, and comprising a part of the Bremen holdings.

Phoenix, Dec. 26.

SANTA CRUZ COUNTY.

An important sale has been made in the Patagonia district, the 3-R group of copper claims having been purchased by C. W. Greene. The group is situated within a few miles of Patagonia, and is in close proximity to the Flux mine, which recently changed hands also, having been sold to Henry Gray. The former owners of the 3-R group had

spent a good sum in developing the property by means of shafts, adits, and cross-cuts, and several orebodies were opened up assaying well in copper and gold. The mine is easily accessible, and offers an excellent site for the reduction works which will be installed in the near future.

YAVAPAI COUNTY.

(Special Correspondence).—In the Lelan mine at Chaparral, several new orebodies have been opened up.—The H. J. Béemer Co. is developing its property by an adit on the copper vein, and by a shaft that recently cut the Ten Spot lode.—The Senator adit, which is being driven by the Commercial Mining Co. (Phelps, Dodge & Co.), is now 3,000 ft. long. The next large vein to be cut is the Snoozer, about 600 ft. from the present breast.—The once famous Peck mine is being re-opened by the Great Peck Mines Co. A new shaft 385 ft. deep has been sunk, and a level (now about 460 ft. long), is being extended toward and under the old workings, from which the bonanza ore was formerly taken, in an attempt to find other valuable orebodies.—The Jessie mine and the Dividend property, both at Chaparral, have again been started up.—The second payment in the Dunkirk deal, arranged a few months ago, has been made. The mine is being moderately developed.

Prescott, Dec. 20.

CALIFORNIA.

AMADOR COUNTY.

Further details of the transfer of the Wildman-Mahoney properties announced in this journal on December 1 are now to hand. The shareholders of the Mother Lode Co., which acquired the mines from Bishop & Spring, have elected J. Overhault, of Pittsburg, as president. The Pacific Coast directors are Homer Wilson, John A. McIntyre, John Ross Jr., and Jackson Dennis. A few months ago a large vein of pay-ore was uncovered in the Wildman, which has determined the company to spend over \$700,000 in development work in the next three years. The Emerson shaft will be completed and a modern mill erected. It is now understood that the back debts of the Wildman mine will be paid by instalments, and that John Ross Jr., the superintendent for the old company, will be retained by the new owners.

EL DORADO COUNTY.

Morgan, Forni, Smeeder & Vaughn made a strike of a good pocket in the Cranes Gulch property last week, taking out in six or seven days about \$7,000. This is a pocket deposit that has produced for years, but not regularly.—Kerr and associates are driving in some very rich gravel in the old Jones Hill property on the Middle Fork of the American River, at the junction of Canon Creek river.—The Beatty claim at Georgia Slide is in good ore. These are old diggings that have produced since 1852, and have a record of several million dollars to their credit.—On the Blue Rock claim, the north extension of Beatty, one man at work upon this property has put in 42 years of continuous labor. This mine has also been a regular producer for 50 years.—Mining is just beginning for the season in this district, as the rains were late in commencing, the last storm being the first of any importance.

El Dorado, Dec. 26.

NEVADA COUNTY.

A new mine is to be opened up at Deadman's Flat, consisting of a group of claims adjoining the Gold Mound, and lying between that property, the California, and Kenosha. This group, known as the Olympus, contains the extension of the Gold Mound lode. The outcrops are bold, and at slight depth the vein becomes solid and well-defined. A force of men has been busy tracing the lode, sinking prospect shafts, and taking samples. A working shaft will be sunk, and the property developed in a thorough manner.—Exceptionally high-grade ore has been recently encountered at the Arctic mine in Canyon creek, seven miles above the town of Washington. Assays range from \$12.60 to \$45 per ton, occasional rich stringers running much higher. The property is in the immediate vicinity of the Ethel and Grey Eagle, and the lode which is being exposed by prospect shafts, is five feet thick. The company engaged in prospecting the Arctic has also acquired the Lecompton mine on Deer creek, just above Nevada City, and will shortly

begin work on that property, operating it in conjunction with the Arctic. The Lecompton was originally located by the late George Hearst in 1857. When the Comstock excitement broke out, Hearst sold it to J. J. Ott, the veteran assayer of Nevada City. Senator Hearst and associates took a fortune from the mine, which has produced upward of a million dollars from the 500-ft. level to the surface. The present company will sink 200 ft. farther and drive drifts on the 600 and 700-ft. levels preparatory to stopping. The mine is equipped with a good hoisting and pumping rig, a modern 10-stamp mill, concentrators, dynamos, and slime plant.—One of the richest strikes made for some time in Nevada county has taken place at the Colfax mine in Willow valley, just east of Nevada City. In driving a cross-cut to develop a vein that was exposed in the 60-ft. shaft, a rich stringer was encountered assaying \$2,700 per ton. The vein is encased in a heavy gouge that is being sacked for shipment. E. A. Work and J. A. McKinney recently secured a bond upon the Colfax.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Lincoln Mtn. Co. has resumed work on its cross-cut adit, which is now in 800 ft. The old Virginia City mine will be developed by 600 ft. of driving, considerably deeper than the old shaft workings from which over \$250,000 were taken.—The Maud S. property, which has produced ore yielding as high as 600 oz. silver per ton, has been leased and bonded to Denver capitalists. The main adit will be driven ahead, in order to intersect the Maud S. vein in about 50 ft.—The Key West Co. is starting its lower adit on the McKinney lode. This will give an increased depth of 215 ft. E. W. Shepard is manager. A power plant for machine-drills will be erected early next year.—Bids have been asked for furnishing lumber for a mill with a daily capacity of 75 tons by the Ramsdell Co. A large force of men is now at work opening up the orebodies, and the extracted ore will be stored pending the completion of the mill. George W. Teagarden is superintendent.—E. E. Grubb has located 20 lode claims and a tunnel site on Alpine Mtn., a hitherto somewhat neglected part of the Virginia City district. Denver mining men are said to be backing the enterprise.—Charles Gilleen and Carl Johnson have recommenced driving the Hidden Treasure adit to exploit their group of 29 lode claims in East Argentine, near the Santiago mine. The adit is in 150 ft.—Pat Walsh, who has been operating the Little Emma mine for the last three years, has encountered a foot of solid lead ore carrying 150 oz. silver per ton; \$750,000 were taken from the upper workings many years ago.—Rees C. Vidlen has located the H. H. Pain tunnel site on Leavenworth Mtn. in connection with the Denver & Transcontinental Railway, the recent surveys for which show that by passing through this tunnel a considerable length of track will be saved. An air-compressor plant will shortly be erected and the work of driving commenced.—Chas. Carlson, who has been prospecting the old Lucky Hesperus vein, has opened up 12 in. of ore that assays 300 oz. silver per ton.—B. J. O'Connell has secured a lease and bond on the Mendota mine, above Silver Plume. This mine is producing excellent lead-zinc ore, both smelting and concentrating. Mr. O'Connell will carry on extensive development work to open up new orebodies.—Dan Williams, representing a Denver syndicate, has taken a bond and lease on the Mammoth property, near Silver Plume. There are large bodies of lead-zinc ore in the mine, which at present prices and with a modern mill can be made to pay.—The first section of the Nashotah Co.'s mill on the Diamond property at Silver Plume is nearing completion, all the heavy machinery being now on the ground. It will have a capacity of 150 tons per day. The second section, having a similar capacity, will be erected early in 1907.—Nelson & Kermode, leasing on the Gold Dirt property of the Empire Tunnel Co., have four feet of ore. The smelting ore has returned over three ounces gold per ton from recent shipments; the concentrate is worth \$50 per ton.—The Pioneer mine at Empire is also shipping ore, running 3 to 5 oz. gold per ton from a two-foot vein.

Georgetown, Dec. 21.

SUMMIT COUNTY.

(Special Correspondence).—The Abundance Co., which owns valuable ground on Mineral Hill in French Gulch, and which for some reason closed down the mine a few months ago, is about to resume work, and push on the main adit toward the centre of the hill. John G. Goodier, the general manager, has just returned from Kansas City, the home of the company, with this information. The property has developed valuable orebodies in its upper workings by shaft and drift-work, and it is well situated among the Union, Wellington, Oro, Mono, and other producers.—H. S. Clark, who has been manager of the Lanyon Zinc Co. for some years past, has resigned his position and the control of this company's affairs in Summit county will be in the hands of Benjamin B. Lawrence, who has accepted the position of Western manager for the Lanyon Co. Mr. Lawrence was for years connected with the Smuggler-Union mine at Tel-

between the Atlantic and Pacific slopes. If the present rate of progress is maintained the connection should be effected in about 12 months.

Breckenridge, Dec. 17.

TELLER COUNTY.

A rich strike has been made on the Four Brothers claim in the Agnes shaft now being operated by the Wabash Leasing Co. Cross-cutting has been in progress at a depth of 250 ft. south of the shaft for some time in search of a vein encountered at 150 ft. with the result that it was found early this week. Assays range as high as \$1,060 per ton. The richest portion of the vein is a stringer from 10 in. to a foot wide, but ore is being broken four feet wide, and is expected to yield from three to four ounces of gold per ton. The mine is situated on the east slope of Beacon Hill.

NEVADA.

ESMERALDA COUNTY.

Owing to the strike of miners at Goldfield the Florence, Jumbo, Combination, Red Top, and Mohawk closed down on Friday, December 21. The remainder of the mines closed on December 23, the lessees stopping work on the following day. Everything in Goldfield is reported quiet at date of going to press, and no outbreak has taken place so far. Notice was served upon the mines mentioned, and the men quit work, some immediately and others at the end of their shift. There is hope of an early settlement. The only mining being done is on the Hayes-Monette and Frances Mohawk leases, and one lease on the St. Ives. Governor Sparks arrived at Tonopah Saturday morning, while he stated his arrival was in a private capacity, it is thought possible his presence may help toward a settlement.

HUMBOLDT COUNTY.

Excitement has been caused in the Seven Troughs district, 25 miles north of Lovelocks by a strike made on property owned by H. W. Knickerbocker and Bent Lloyd, within a quarter of a mile of the new town of Vernon. The vein is from seven to eight feet wide, and assays have run high. A large number of properties have changed hands in the district on the strength of this strike. Knickerbocker & Lloyd are opening up the vein as rapidly as possible and some high-grade ore is being sacked for shipment.—In the same district four big properties have already been developed extensively, and some ore has been accumulated. The best showing is being made by the Fairview, Owens, Moler, and Knickerbocker. The Seven Troughs district has favorable conditions for cheap and rapid extraction, and the proximity of the Southern Pacific railroad, which is within 25 miles, furnishes adequate transportation facilities.

LANDER COUNTY.

(Special Correspondence).—It is announced that the operations of the Gold Park Mining Co., at Gold Park, Nev., for the month ending December 10, 1906, were conducted at a profit of 24% on the total investment. The company is shipping ore steadily to the Salt Lake smelters, and is preparing to build a new 20-stamp mill in the spring.

Austin, Dec. 15.

NYE COUNTY.

The Fairview Co. at Round Mtn., will continue development work this winter, and block out as much ore as possible until it is practicable to build a new mill in the spring. The ore now on the dumps assays from \$12 to \$40 per ton. The adit is in 360 ft., and a raise beginning 60 ft. from the face of the tunnel has tapped the bottom of No. 1 shaft. From there drifts will run both ways on the exposed orebody. The vein is 14 ft. wide in good milling ore and no hanging wall has yet been encountered. In No. 2 shaft they are still driving on an 8-ft. lode of good milling ore.

The new camp of Duluth situated 48 miles north of Luning, in the northern corner of this county, is attracting much attention, although the original locations were only made last July. On the Climax, July, and Black Mule properties there are 26 sets of lessees, and all are said to have high-grade ore in sight. The Duluth Co. owns the Red Dog, Reno, and Reno Extension. A tunnel has been advanced 26 ft. on the Reno, disclosing a well-defined vein three feet wide. The outcrop on this property is 14 ft. wide and car-

luride. Mr. Clark goes over to the Colorado Zinc Co.—The Silver King mine in Montezuma has been purchased by W. S. Leebrick and J. R. Roots of Idaho Springs. The property consists of several valuable claims, the principal of which is the Silver King, which has been worked for the past 30 years, and has a record of production of over \$200,000.—The transfer also carries a concentration mill and the whole deal was closed for \$20,000. The Silver King ores are principally silver, lead, and zinc.—Another important deal in the same section is that of the White Quail group on Cooper Mountain, which has been sold by Phillip Bianchi, Louis Dellamarte, and others to J. P. Simon of Superior, Wis., for \$20,000. A company has been formed to work the property on a proper scale at once.—The Kokomo camp is enjoying a big boom and all available buildings are filled and new ones being erected.—The new machinery has arrived for the large mill at the Breene mine, and the work of installation will be started immediately.—The large concentrating and separating Wilfley mill is running at its full capacity and making large shipments of zinc and lead products. A rich strike of \$200 ore was made last week on this property.—The big Vidler drainage and transportation tunnel which is being run through the Continental Divide at Argentine Pass, is being pushed along as fast as money and men can accomplish it. From Summit county side, the work is progressing at a rate of 250 to 300 ft. per month. On the other side about 200 ft. per month is being made. This work is not only opening up wonderfully rich mineral veins, but when completed will furnish a short road for connection

ries ore rich both in gold and silver. On the Silent Friend, owned by Bruener & Co., a shaft has been sunk 68 ft. and in the bottom specimen gold ore is said to have been struck. On this property the vein outcrops the full length of the claim. The formation of the district is rhyolite, with later dikes traversing its length with a general strike east of north. Much of the quartz is green in color, but carries no copper. The new town of Duluth is five miles northeast of Lodi Tank, and 10 miles west from Ione. A pipe-line is to be run eight miles from the Shoshone range, which will furnish ample water.

LYON COUNTY.

Edward Clay and G. D. Johnstone have obtained possession of the old Crabbe mine near Yerington, and are pushing work. Large bodies of excellent ore have been opened up, samples from a vein in the Rockland, one of the Crabbe group, showing free gold. The hills surrounding Yerington are now covered with working miners, most of whom are finding ore.

OREGON,

GRANITE COUNTY.

Development work is to be started at once on the Oregon-Monarch claims adjoining the Red Boy mine near Granite. The Oregon-Monarch property is owned by Chicago capitalists, and comprises 11 claims located on the same vein as the Red Boy. Power for machine-drills will be obtained from the Red Boy compressor.—Eighteen inches of good ore have been opened up on the Golden Star claim situated near Granite and located on the same vein as the Magnolia and Independence. The ore was encountered in a drift which is being driven on the Magnolia lode. The Golden Star is owned by A. P. Jones and associates.—Arrangements have been completed for opening the lodes on the Katydid and Katydid's claims on Magnolia Mtn., through the Snow Bird adit, which is near the dividing line of the two claims. The Snow Bird vein is rich in free gold, many thousand tons of ore from this vein having been run through the Magnolia mill during the past year that yielded a handsome profit.—A force of miners has been put to work in the long cross-cut at the St. Anthony mine near Alamo. Development operations will be continued through the winter until the claims are thoroughly opened. The St. Anthony Consolidated Co. owns 30 claims, upon which about \$60,000 has been spent to date. Although the lodes have not been opened to any depth, there are excellent surface showings of free-gold-carrying ore.

WASHINGTON.

SPOKANE COUNTY.

A compressor plant and power-drills have been ordered for the Mohawk mine, west of Spokane. Much work has been done on the property during the last few years, but development work was slow and expensive, with only hand work available. Much good ore has already been encountered in the long lower adit, but the main body is beyond the present face of the workings. The Great Northern railroad now passes directly by the mouth of the adit, and the Nighthawk ore can be mined and put on the cars for shipment at a minimum cost.—A strike of zinc occurring in three feet of gold-bearing ore was made on the W. & K. mine, 33 miles south of Spokane, a few days ago. The property is owned by H. N. Wentworth, of Spokane, and H. L. King, and Fred. King, of Connell. It has been opened by two 15-ft. shafts and by one 35 ft. deep, which have proved the vein for a length of 600 feet.

MEXICO.

CHIHUAHUA.

Chas. M. Schwab and associates of the San Toy Mining Co., have purchased the Central and Juarez mines in Santa Eulalia, for a consideration said to reach \$1,000,000. The San Toy Co. is also negotiating for the purchase of the properties of the Santa Eulalia Exploration Co., including the Buena Tierra, Nueva Santa Eulalia, and others. It is stated that the price practically agreed upon is \$1,250,000 gold, the original price asked being \$1,500,000. The management of the San Toy Co., contemplates building a large smelter near Chihuahua for the reduction of its own ores and a general custom business. The company is now build-

ing an aerial tram from the Galeana and Bustillos mines to a spur of the Mexican Central railroad at the foot of the mountain west of Santa Eulalia. A second tram will be built connecting the company's newly acquired properties with the main line from the Galeana and Bustillos, enabling ore from all the mines to be carried over four miles of mountains from the mines to railroad for 15 cents per ton.

JALISCO.

Ore assaying 20,250 grams silver, 40 grams gold and 20% lead has been struck in the Santa Clara claim of the Santo Domingo group in the Hostotipaquillo district. Simultaneous with this discovery, the pay-streak of the Santa Clara vein widened to four feet. The adit is now in 251 ft. and two drifts are being driven. Recent development work has

Map of New Mexico.

disclosed rich ore in other portions of the Santo Domingo property. In addition to six adits and two drifts now being run, three new adits have been projected. A wagon-road will be built from the mines to Magdalena, in connection with which a cable road will be constructed from the top of the Santa Clara Mtn. to a point near the Santiago river to facilitate ore transportation.

SONORA.

A deal has been completed by which Thomas F. Cole, John Ryan and associates have acquired heavy interests in the Greene Consolidated Copper Co. Messrs. Cole, Ryan and Greene already have large interests in the Cananea Central Copper Co., and these two companies, controlling as they do practically the entire camp of Cananea, will be merged into a new corporation, to be known as the Greene Cananea Copper Co. Stock to the amount of \$50,000,000 will be issued by this corporation, which will exchange this issue for Greene Consolidated upon the basis of \$30,000,000 for the property, and for the stock of the Cananea Central upon the basis of \$20,000,000 for this latter property. Cash has been provided for enlargement of plant and development. The new company will be incorporated under the laws of Minnesota, with nine directors representing the interests concerned.

It is understood that the Sonora Bonanza sale to the Guggenheims is at present considered off because of the refusal of a group of shareholders to come in on a pooling arrangement necessary in order to bring about the transfer of the property in the complete manner the prospective purchasers insist upon. Those standing out hold that the property has advanced to a point where its success is assured, and that parting with it under existing conditions is undesirable.

Personal.

E. N. VAN CORTLANDT is at New York.

WALTER M. BRODIE recently visited Prescott.

F. L. BOSQUI is on his way to Deadwood, South Dakota.

NORRIS ENGLISH has returned to Oakland from Mexico.

A. P. ROGERS is on his way to Colombia, to test dredging property.

M. VALENTINE is on his way from London to the northern Transvaal.

J. H. MEANS has returned from Mexico, on a visit to San Francisco.

LEO VON RONSEBERG is on his way from Prescott to New York.

HENRY F. LEFEVRE has returned to New York from Nicaragua.

ALFRED ALLEN has returned to Oakland from a season's work in Alaska.

F. N. RHODES is employed at the Calumet & Arizona mine, at Bisbee.

E. E. CARPENTER is assayer for the Tonopah Mining Co., at Tonopah, Nevada.

ROBERT BELCHER has come from Goldfield to spend the holidays in Berkeley.

W. S. GIFFORD is in charge of diamond-drill explorations near Stanford, Montana.

S. A. IONIDES is with the Penn-Wyoming Mining Co., at Encampment, Wyoming.

HENRY G. ADLER has been appointed general manager of the Foster mine at Cobalt.

ARTHUR J. RUSSELL, as managing director, is inspecting the Tolima mine in Colombia.

THEODORE BECKER is now chief assayer at the Garfield plant of the A. S. & R. Co., in Utah.

F. T. HAVARD, smelter manager for the Copiapo Mining Co., has returned to Chile from New York.

PHILLIP POORE is expected at the Barranca mines, in the Hermosillo district of Sonora, Mexico.

E. G. SPILSBURY is lying at the Nogales Hospital with a broken leg. He is recovering satisfactorily.

JOHN C. TREADWELL is now manager for the Coahuila Mining & Smelting Co., in Coahuila, Mexico.

C. HENRY THOMPSON, of the firm of Thompson & Gilliam, has left Los Angeles to inspect several mines in Mexico.

F. C. CARSTARPHEN has returned to Denver from Routt county, where he has been making examination of cement deposits.

LANE C. GILLIAM has been appointed manager of the Boca del Cobre mines, at San Luis del Cordero, in Durango, Mexico.

RICHARD A. PARKER, having visited British Columbia, Idaho, and Mexico, is on his way from Denver to Boston, to see his clients.

A. W. WARWICK, consulting engineer to the Sierra Madre Development Co., has returned to Denver from a long trip in Mexico.

GODFREY D. DOVETON, of Doveton & Purington, is at the Esperanza mine, El Oro, Mexico, conducting a metallurgical examination.

ROSCOE H. CHANNING, JR., has resigned as general manager for the Utah Consolidated Co., and will be president of the Cerro de Pasco Mining Co., in Peru.

PHILIP ARGALL has been appointed consulting engineer to Stratton's Independence, Ltd., to fill the vacancy caused by the resignation of GEORGE A. SCHROTER.

JOHN C. TREADWELL has resigned as manager of the Sahuayacan Mining Co., to take a like position with the Coahuila Mining & Smelting Co., at Viesca, Coahuila, Mexico.

C. COLCOCK JONES is in Arizona for several weeks examining mining properties in the Superstition and Bradshaw

mountains, and will return to Los Angeles at the end of December.

L. W. TRUMBULL, of Laramie, Wyo., is examining mineral properties in Gunnison and Chaffee counties, Colo. Shortly after his return from Colorado he will make a short trip to Sierra county, California.

FRANK C. LORING has resigned as general manager for the Trethewey Silver-Cobalt Mine, Ltd., at Cobalt, Ontario, but he remains consulting engineer. He will engage in a general consulting practice.

C. M. FUELLER, formerly at 1750 California St., Denver, has moved to 221 Empire Bdg., and in future will do a general consulting engineering and examination practice. Mr. Fueller has been appointed consulting engineer of three large companies in Colorado and Utah.

Obituary.

J. MORGAN TAYLOR, a mining man known from Nome to South America, died at Sacramento on December 20. He left Goldfield for Lodi, Cal., early on the morning of that date, and was taken ill with pneumonia on the way. Upon arrival at Sacramento, friends who were on the same train, telephoned for an ambulance, and sent him to the Sister's Hospital, where he died in the afternoon. Relatives of the deceased at Lodi were notified and the remains were expressed to that city and interred on December 24.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE lining for by-product coke ovens should be made of fire-brick high in silica, whereas that for a rotary cement kiln should be high in alumina.

THE gold lodes of the Appalachian region, from Nova Scotia to Alabama, are in quartzites, slates, schists, and gneisses of either Cambrian or Algonkian age.

THE antimonial lead, which is an undesirable by-product in lead smelting, is used in making coffin handles. The purer forms of antimony, free from arsenic and lead, are used in manufacturing type and babbitt metal.

MOLYBDENITE, which is often mistaken for graphite, is the sulphide of molybdenum. The demand for it has increased on account of the discovery, comparatively recent, that it gives very beneficial properties to steel.

ONE of the causes of loss in the transmission of compressed air is pumping the air of the engine room rather than that drawn from a cooler place. The loss amounts to from 2 to 10 per cent.

WHEN mercury is sub-divided minutely, as in stamp-milling, it is said to be 'floured'; when the globules become coated with grease, fine slime, manganese oxide, etc., so that they will not coalesce, the mercury is said to be 'sickened'.

COMPARATIVELY little has been heard about radium this year, due to the fact that the cost of the salt is almost prohibitive, and that the experiments to date, while interesting, have proved little or nothing as to the actual value of the element.

A RECENT British consular report states that the Ainsmara mines, situated 11 miles from Constantine, contain rich lodes of chlorophosphate of lead. Other beds of carbonate of lead have recently been discovered near Batna, but so far have remained unworked.

THE difficulty encountered in applying electricity to hoisting is due to the trouble of satisfactorily connecting motors to the existing drum. Electric hoisting is not only economical, but is simple of control, and the motors afford a uniform torque, which lessens the fly-wheel effect of the winding engine.

THEORETICALLY, a miner working underground requires only $6\frac{1}{2}$ cubic feet of fresh air per minute for respiration, the absorption of moisture, and the dilution of carbonic acid gas. This, however, assumes that all air after having been breathed is immediately removed, without mixing with the surrounding atmosphere, a condition impossible to fulfill.

MICA is used chiefly in electrical machinery, as an insulator between the segments of commutators. For this purpose the mica must be soft. The General Electric Company gets its mica from its own mine near Sydenham, in Ontario. Large sheets of mica are in demand for lamp chimneys and other novelties. Scrap mica is ground fine for fire-proofing material, as a lubricant, and for wall papers.

MANY mining engineers have disputed the superiority of the compound engine for winding, owing to its short

runs and frequent stoppages, and the large proportion of its power taken up in accelerating the load. It is possible, however, to install a four-cylinder compound engine of sufficient power to dispense with any live steam in the low-pressure cylinders, which latter condition is seemingly the cause of much of the inefficiency of most existing compound engines.

IN regard to operating a dredge in cold regions, the Conrey Placer Mining Co. works in the winter at Ruby, Montana, where for several months the temperature is 20° below zero. They are enabled to work in the winter by building a dam around an area of ground sufficient to equal the capacity of the dredge during the cold weather. The effect of submerging the gravel is to keep it soft. The washing is done in sluices on a barge, the sluices being enclosed and kept warm with steam.

ACCORDING to Chas. G. Yale, of the U. S. Geological Survey, in his report on the output of borax during 1905, the production of that mineral is almost entirely confined to the State of California, and to the counties of San Bernardino, Inyo, and Ventura. Only small quantities are occasionally taken from the marshes in Nevada, where a little work is carried on during the summer months. The total output of crude borax for the year 1905 was 46,334 short tons, as against 45,647 tons in 1904.

PIPES supplying air to rock-drills should be of a size to permit the passage of air at a velocity not greater than 25 to 30 ft. per sec., while all bends and angles (especially short ones) should be avoided, as they add greatly to the friction of the air, and thus decrease the pressure. The friction of the air is proportional directly to the length of the pipe, and to the square of its velocity. For this service, pipes up to 5 in. diameter are provided with couplings, above that with flanged joints made up with gaskets. Great care must be taken that these joints are perfectly tight, as the loss, even from a pin-hole, is considerable.

IN the manufacture of cyanide, ammonia, as a nitrogenous material, is combined with carbon so as to form sulphocyanide as an intermediate product. This is converted to cyanide by the oxidation of the sulphur to sulphuric anhydride. Nitric acid is used. The sulphocyanide is decomposed and the nitric acid is recovered. The operation takes place in a series of earthenware jars connected with each other; they are fitted with an exit pipe for the gases and an inlet pipe for the steam that heats and agitates the contents. The first jar is furnished with inlets for the sulphocyanide and nitre solutions, for vitriol, and for the return of the recovered nitric acid. The second jar is fitted to receive the water and to dissolve the hydrocyanic acid returned from the condensing apparatus.

WHERE compressed air is used, it is important that all joints in the air mains should be carefully made to prevent any possible leaks, as air leaks are more expensive than steam leaks. At intervals it is well to test for leaks by allowing the air at full pressure to remain in the pipe long enough to observe the gauge. To render pipes accessible for inspection, they should, if buried, be carried in boxes sunk just below the surface of the ground, and all low points which might form pockets for the accumulation of entrained water should be avoided, as they obstruct the passage of the air. It is also advisable, in long, uneven lines, to provide an opening near the end, for occasionally blowing out water. Long lengths of pipes on the surface or shafts where the temperature is subject to changes, should be provided with expansion joints.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

The Need of Experience.

The Editor:

Sir—Are you not hard upon the young mining graduates mentioned by E. D. C. in your issue of December 1? An expert millman yourself, you hardly realize that so evident a piece of knowledge as the care of amalgamated plates can escape the attention of a mining graduate. In his college course the steps of a chemical analysis, the demonstration of the mathematical properties of asymptotes, the system of crystallization to which a mineral belongs, are as all-important to him as the dressing and care of plates. He learns without discrimination, crams for examination, and forgets as rapidly as possible a large part of the knowledge both useful and useless thus acquired. I would venture to say, however, that our men who take our instruction involving practice work in ore-dressing learn by actual experience the care of amalgamated plates in a way which they do not forget. On graduation most men have not acquired the habit of study, and accordingly do not read up especially where, as in this case, the matter seems self-evident, and accordingly it seems severe to call them 'chumps.'

In the account of the clean-up one can hardly understand how it would be possible to clean and squeeze the amalgam, and yet leave it no metal which, upon retorting, would not give considerable residue.

L. S. AUSTIN.

Houghton, Michigan, December 12.

Black Sand.

The Editor:

Sir—Your editorial remarks concerning Dr. Day's work on 'black sand' are much to the point. The gentleman is no doubt doing over again much that has been done before, but there is the hope that he will do it better, and the almost certainty that his results, failures as well as successes, will be published to the enrichment of a subject that possesses but a scanty literature. Beach or black sand has been exploited for gold and for steel for many years. Twenty years have passed since I saw samples of steel made from the magnetite winnowed from the sand hills in San Francisco itself, and heard of the formation of a company which was to go into this manufacture on a great scale. Even before that time I had examined for clients certain deposits along the coast of southern Oregon, and I may mention incidentally that my conclusion as to their workability was that the only obstacle was the lack of gold—steel not being an object with us. This conclusion I still believe to be sound. Nevertheless, the metallurgy of such materials has made advance enough of late years to give some hope and even expectation that the time may soon come when a number of those deposits may be successfully worked, either for steel or for gold, or for both. Magnetic concentration increases the chances, for by this means the iron content can undoubtedly be got in a comparatively pure condition; and the cyanide process, if it meet the claims of some of its advocates in this direction, is likely to be instrumental in gaining the gold of the richer sand. But some will say that there is no rich sand; and in this I agree, if we limit ourselves to the material along the sea coast in general, and along such streams as the Snake river, for it is rare indeed that the assay shows more than a dollar per ton, while great areas carry only a few cents per yard. Those accidental happenings mentioned by the newspapers, where great amounts of gold are reported, I think must be wholly fic-

titious, in so far as the class of beach and river sands are concerned. They are most probably, if true at all, the results of the clean-up from some placer washing, and are therefore outside of the subject in hand. I hope that investors will not be led into this industry from exaggerated ideas of the wealth of these deposits, for they are, with the exception of some few restricted areas where conditions have favored the concentration of the gold, quite poor in that metal, whatever be their content of magnetic iron. I have myself made many assays—some hundreds, I presume—and my recollection is that I never got as much as ten dollars per ton in any case when operating on the natural sand, that is, sand which had not been artificially concentrated or winnowed, to raise its value. I have heard the opinion advanced by the beach miners of Coos and Curry counties in Oregon, where the working of such deposits has been long a recognized industry, that ten cents per yard would satisfy them, and that they did not think that the average contents of any large area of workable sand was more than half that. With this view the results of my assays forced me to coincide.

HERBERT LANG.

Oakland, December 4.

California Place Names.

The Editor:

Sir—The duties of a mining engineer are numerous and diverse. Some are plainly evident, others are not so. In fact, some are not recognized as duties in any sense. In this day and generation, when all lines of human activity, while preserving inviolate their individuality, still draw closer together, the mining man, in common with the other workers, finds at hand more and greater work to be done. What yesterday failed to attract his attention becomes today a small bit of work necessary for him to do. Thus we are slowly reaching a higher level of society. There is one small bit of necessary work which appeals to me strongly as being particularly within the province of the mining engineer to aid in accomplishing. This is the preservation of the old California place names.

Our place names have more than the mere worth of attached sentiment, great as this is; they also represent one of the strongest bonds uniting present with past, urging us on to greater and greater endeavors to perfect in all ways the future. Although we, as a people, do not yet adequately realize their full significance and value, each year serves greatly to increase this true realization. If we of today fail to preserve the old landmarks and milestones of progress, we shall be held to blame by posterity.

The early history of California deals with the hard work of founding a commonwealth, of labor in the mines, and on the great plains. The records of this have been preserved in the names of the various geographical and topographical points, of towns, and of all the other features of the country needing specific titles. The preservation of all these rests upon those among us who not only comprehend their full meaning, but who also are personally familiar with the places or things named. There have been a very few effectual, though desultory, movements in the State to preserve certain place names, but wide-spread attention to the subject is greatly needed, else we shall soon lose what never can be regained.

Of all men whose duties call them from the town to the mountain, from the atmosphere of intellectual growth to the fields of hard labor, the mining engineer and geologist stand pre-eminent. For this reason these men can and should help to keep the old names in their original purity, not only by using them correctly in speaking and writing, but also by spreading broadcast a

better appreciation of all for which they stand. The famous old mining town of Murphy's Camp is a good case in point. The popular tendency to shorten everything has reduced the name to plain Murphy—utterly bereft of both meaning and charm. Another instance of this gradual loss is found in a recent change in the name of the railroad station at the old mining camp at Shady Run to Midas. One has but to glance out of the car window here to realize the peculiar appropriateness of the original.

Again, at the famous scenic point just above Colfax, where the railroad rounds a sharp curve many hundred feet above the American river, the old and significant title of Cape Horn has been altered on the railroad schedules to Caporn. We need place names, need them more every day as we travel further and further from the olden times when the foundations of our State were laid. Therefore it is urged upon all mining men

Transport Under Difficulties.

The Editor:

Sir—General managers sometimes make mistakes. As a result of an error by the respected manager of the Mazapil Copper Co. at Concepcion del Oro, Mexico, in giving an order to the Allis-Chalmers Co. for a rock-crusher, the writer is enabled to give an account of an engineering feat which he believes will be interesting to the readers of this journal.

Some time ago our management decided, wherever possible, to adopt labor-saving devices. One of the first steps taken was to do away with hand-sorting of the copper ore as it came out of the mine; a crusher of the Blake type was available, but it was found, after a time, to be of insufficient capacity. After seeing the economic benefits to be derived from the new system, it was decided to order a machine of a larger size, 15 by 9 in., but in send-

A Crusher in Mid-air.

Mexicans Working a Crab.

that they do their share intelligently both to preserve these names and to widen the general knowledge of their ultimate meanings.

JOHN A. REID.

Stockton, December 13.

Cyanide Practice at Kalgoorlie.

The Editor:

Sir—With reference to Mr. Brett's long letter in your issue of December 22, of which you kindly sent me an advance proof, I notice that in spite of the space at his command Mr. Brett does not apparently deny my suggestion that in his so-called tube-mill versus pan tests he actually fed into the tube-mill with the sand to be re-ground more slimed (finished) product than sand to be re-ground, although he must have known that such a procedure would seriously diminish the duty of the tube-mill.

As Mr. Brett does not deny this, his long personal explanation calls for no other comment from me; but I would like to add that the pan work at the Ivanhoe has impressed me so favorably that were I laying down an installation of pans I should deem myself fortunate if able to secure the services of Mr. Brett for this purpose—so efficiently have the pans been worked at his late mill at Kalgoorlie.

ALFRED JAMES.

London, December 5.

ing off the order it was not mentioned that the crusher should be a sectional, for this was necessary on account of the absence of any proper road between the railway and the mines. The latter are situated at an altitude of 2,000 ft. above the terminus of the former, the distance between the two points being three miles.

The crusher arrived and after dismantling it as much as possible, we found that the main casting weighed about five tons; a very strong cart was made and by repairing the road a little, the machine was ultimately landed at a point where it was scarcely possible, excepting at tremendous expense, to proceed any further with the cart. An aerial tramway was then decided upon, the construction of it being entrusted to the superintendent of the over-head ropeways belonging to the company, an energetic, intelligent Mexican. First, an especially strongly constructed discharge station was erected, and from this two one-inch steel ropes of the best English make were carried over the bed of the river and on to a point at the top of the mountain. The horizontal distance between the discharging and receiving stations is about 510 metres (1,673 ft.) and the elevation is 250 metres (820 ft.). At the discharge terminal of the ropeway, a strong bent was built; over this the cable passed, the ends being anchored around large rocks and securely clamped.

The crusher was slung on the two guide-ropes by the ordinary kind of transportation carriers, two wheels inside two flat-iron discs, securely clamped together; the

pulling rope, which was worked by a strong crab turned by a few Mexican laborers, was of one-inch diameter and of the same make as the guide-ropes. The speed of hoisting was necessarily very slow, but the casting was landed on top of the mountain in one ordinary working day. From the discharge station to the site of the crusher, the road was fairly even and the work of completing the transfer was easily accomplished. While there was the extra cost of transport due to having the crusher shipped in one casting; on the other hand, there would be the maker's extra charge for supplying the machine in sections, and, as anyone knows, the stability of the crusher is fully established in the former case; in a word, a general manager's apparent mistake; by the use of sound intelligence and a determination to surmount trouble, will prove to have been for the better.

I am indebted to Mr. Chester-Master for the photograph of the crusher in mid-air. As can be seen, the crusher was shipped over the cable together with the wagon on which it was transported from the railway station.

JOHN COOPER,

Gen. Supt. of Mines, The Mazapil Copper Co.
Concepcion del Oro, November 12.

GRIFFITHS, referring to the work of Strutt and Rutherford, and assuming the earth to be in thermal equilibrium, states even if the whole of this interior heat be due to radium alone, the mean quantity per cubic centimetre can not exceed $1.75 \text{ by } 10^{-13} \text{ gram}$. The conclusion of Rutherford, based on somewhat different values for the constants involved, gives an equivalent of $1.52 \text{ by } 10^{-13}$, while Strutt has found that poorest igneous rock he examined (Greenland basalt) contains more than ten times this quantity, and an average rock 50 to 60 times the amount. The assumption that the earth is cooling only aggravates the difficulty, and facts appear to tell against the theory that it is getting hotter. Also we must take into consideration the heat due to the existence of uranium, thorium, etc. He concludes that either the rate of heat production by radium diminishes as we approach the centre of the earth, or the interior of the earth differs markedly in constitution from the exterior crust. Mr. Strutt, arguing from known data, assumes the maximum temperature at the bottom of a crust or about 45 miles in thickness is in the neighborhood of $1,530^{\circ} \text{ C}$. Such a crust would contain about $\frac{1}{30}$ of the earth's volume, and assuming that throughout this crust the radiant heat energy were of the average of that exhibited by many samples examined by Strutt, then the temperature of the earth could be maintained until our stores of uranium suffered sensible depletion.

METALLIC TELLURIUM is extracted from the slime which is the waste product of the electrolytic process employed at the Baltimore copper works in the treatment of copper-mattes from the West. This residue, after the removal of silver and copper, consists principally of the sodium salts of silica, selenous, and tellurous acids, the last named being in large excess. The method consists in the precipitation of the metal and its conversion into basic tellurium nitrate. This finely crystallized salt serves as an excellent means of obtaining pure tellurium. The basic nitrate is decomposed by heat; the oxide thus obtained is dissolved in hydrochloric acid; and from this solution the metal is re-precipitated by means of sulphur dioxide. Crystallization of the basic nitrate from a nitric acid solution removes selenium completely from the tellurium, and also furnishes a convenient method for the separation of other metals.

Two Special Alaskan Maps.

Two special maps of the Nome region, Alaska, recently made by topographers of the United States Geological Survey will be welcome to the many people interested in that rich and growing district. Ever since the discovery of gold placers on the Seward Peninsula in 1898 that general area has been as attractive to the public as was the Klondike in the spring of the previous year. Miners, operators, and investors have flocked into that part of Alaska and numerous towns have sprung up. The chief of these, in fact the metropolis of the north, is Nome. From a rough mining camp it has been rapidly transformed to a corporate city, with its own government and most of the modern improvements and facilities that are found in cities of equal size in the States.

A peculiar feature of the placers which have made Nome famous is the occurrence of beach deposits. These extend along the shore of Bering Sea in front of the present location of Nome for a distance of twenty miles. The value of the gold taken from these beach placers is estimated at no less than \$1,000,000, but this is small compared with the value of the gold taken from the nearby creek and bench claims, which have already produced \$30,000,000 and are still adding to the world's wealth of yellow metal.

The importance of this region was early manifest. In 1899 the United States Geological Survey made a geologic and topographic reconnaissance of the southern part of the Seward Peninsula. The data and maps published as a result of this expedition furnished valuable information to miners and investors, especially in regard to roads, ditches, available sources of water supply, and other features that are important in the economic development of mines. These maps lack, however, the details that are essential in maps used for such engineering purposes as making preliminary estimates, laying out grades and locations for future construction, etc., and it was to furnish additional data that a more detailed map of this region was made. It is published in two sheets, called the Nome and Grand Central specials.

The Nome special includes the area lying between 64 deg. 25 min. and 64 deg. 40 min. lat. and 165 deg. and 165 deg. 30 min. long. The Grand Central Special includes the area between 64 deg. 40 min. and 65 deg. lat. and 165 deg. and 165 deg. 30 min. long. These sheets are published on a scale of 1:62,500, approximately one inch to the mile, with a contour interval of 25 ft. referred to mean sea-level as a datum. The area embodied in these two sheets contains most of the placers in the Nome region, also the streams and their sources from which the operator takes water to sluice out his gold and on which he is absolutely dependent. From the elevations and other data shown on these maps the making of preliminary estimates of distances, grades, and locations for ditches, roads, water-power, and other construction work will be much facilitated.

THE value of zinc ore depends largely upon the presence of impurities, especially iron, manganese, and lime, which increase the corrosion of the retorts, and lead, arsenic, and antimony, which contaminate the spelter. The value of the ore is also affected by its character, whether oxidized or sulphide, or a mixture of both, the sulphide ore must be roasted, but yields a diminished weight for the subsequent treatment, which is the most expensive part of the process; the oxidized ore escapes preliminary treatment, unless it be carbonate, but suffers no diminution in weight. The preliminary treatment of ores which are mixtures of sulphides and oxides is often troublesome.

Primitive Methods.

The accompanying photographs we owe to the courtesy of Mr. Frank E. Shepard, of the Denver Engineering Works. They illustrate some quaint devices still employed in a remote part of Mexico.

Fig. 1 shows the rollers and buckets of a rudimentary tramway. The cable is made of six No. 9 telegraph wires—probably stolen. The buckets are 5-gal. oil-cans tied fast to the cable. When the tram is running it

Fig. 1. Rudimentary Tram.

Fig. 2. Bridge Built of Vines.

requires a man at each roller to lift the buckets over; the tram is about 800 ft. long and has about a 25% incline. If the tram starts to run away the boss calls down the line to stop the buckets and the whole thing becomes arrested on account of the buckets getting mixed up with the rollers.

Fig. 2 illustrates the use of vines in making a bridge at Atoyocuillo. No iron, wire, rope, or hide is used in this construction. The material all grew close to where

the bridge was built. Mr. W. H. Holcomb, on the bridge, weighs 230 lb. The span is about 150 ft.; the height above water is 16 feet.

Fig. 3 shows a water-power hammer. This hammer strikes about 90 blows per minute and all the machinery was made on the ground.

Fig. 4 represents the iron works at San Raphael under the *pueblo* of Itundujia. In this place about 1,000 lb. iron ore is reduced per day of 10 hours in an open fire with charcoal as fuel. Blast is supplied from a water-

Fig. 3. Water-power Hammer.

Fig. 4. Old Iron Works.

blower in which the water which carries entrained air is given a fall of about 15 ft.; the air is separated into a receiver built of stone and is led through a stone pipe to the forge. The iron melts out of the ore and collects in the bottom of the forge; a cold bar about 1½ in. diam. is inserted into the molten mass and turned until it collects enough for a bar; it is then hammered out by a water-power hammer. From the time the ore is put on the fire until it is in the form of a bar does not exceed 30 minutes. The material produced is about the same grade as the Swedish iron imported into the United States. To mine the ore and make the iron costs less than two *centavos* per pound finished. The waterfall to the right of the picture is 40 metres vertical.

THERE are two districts in Kentucky where zinc and lead occur. That lying in the western part of the State is now producing small quantities of ore in connection with the mining of fluorspar. In central Kentucky, near Lexington, there is also an area where zinc and lead occur, though very little has been produced.

A New Cyanide Plant.

Written for the MINING AND SCIENTIFIC PRESS
By MARK R. LAMB.

With the introduction of an economical method of washing slime, the cyanide process has undergone a decided change.

Formerly it was the aim to make as little slime as possible, because, although the actual extraction by the solution was better from slime than from sand, the separation of this solution from the slime was slow, expensive, and unsatisfactory. With one of the recently perfected vacuum-filters in mind, however, the designing engineer now plans to grind fine, or slime the entire product of the mill. The accompanying drawing exhibits the design of a plant to treat ores which run about as follows:

Gold	\$60 per ton
Silver.....	None
Concentrate.....	.5%
Free gold.....	.5%
Lime required to neutralize.....	10 lb.
Cyanide consumed per ton.....	1.2 lb.
Concentrate worth.....	\$400

The ore is rather softer than ordinary California gold-bearing quartz. This plant is designed along the new lines and is expected to treat 140 tons per day, crushing to a maximum of 150 mesh. The crusher, a gyrator, is not shown. The ore will be fed to the stamps of a size not exceeding one and one-half inches. The stamps will weigh 1,600 lb. The mortars will be very narrow, with no arrangements for inside amalgamation. Each stamp is expected to crush 7 tons through 10-mesh in two hours. This result is being attained with stamps of similar weight on ores of approximately the same hardness.

Stamps weighing 1,600 lb. may seem too heavy. The cam-shaft will be 7.5 in. diam. with five stamps to a shaft. The preponderance of weight will be in the boss-head, which will be 9.5 in. diam. Stems will be 4 in. diam. and are not expected to break. This may also be considered heresy, but 30 stamps weighing 1,450 lb. with 3.5 in. stems have now run nearly a year without breaking a stem. The mortar foundation will be of concrete and very broad. Muntz metal apron-plates are shown, as these have a life in cyanide solution approximating four times that of copper. It is more than likely that plates will not be used, as what free gold is in the ore is very fine and will dissolve promptly.

Cone classifiers are shown below the battery-plates, for roughly separating sand from slime before concentration on vanners. The tailing from the vanners goes to a large de-watering cone, the underflow from which goes to tube-mills for re-grinding. For this particular work, a Dorr classifier will probably be installed instead of the cones, as the sand can be sent to the mill with much less water, which condition is much better for efficient work in the tubes. The Dorr classifier will require practically no attention as compared with a cone.

The tube-mills are to be 4 ft. diam. by 12 ft. long and lined with soft iron plates 1 by 8 in. by 12 ft., the joints covered with 3-in. angle iron, 12 ft. long. It is expected that this lining will last 12 months. From the tube-mills the pulp will go to cones, or a Dorr classifier, the oversize returning to the tubes and the slime to the 6-ft. thickening-cone before concentration. It was hoped that slime-tables would be satisfactory for concentration at this stage, but experiments now being made point to a return to the canvas plant as the only means of extracting all the mineral.

This last concentration is the vital point of the process, as any mineral going over with the slime to the cyanide plant will carry all its value to the waste dump.

A canvas plant for such a tonnage will cover a large area, since using a 10-ft. width per ton of dry pulp as a

basis of calculation, a figure recommended by Mr. A. G. Kirby, there would be required a distribution length of 1,400 ft. with a width of canvas of at least ten feet. If placed on two floors, the space required in the mill will be 17,000 sq. ft., or about three times the area now covered by the slime-tables in the plan. It was the intention to concentrate about one-third of the pulp, taking this quantity from the bottom of the 6-ft. cone, but it will probably be found necessary to concentrate the entire product over canvas.

The remainder of the plant is simple and consists of settlers, agitators (equipped with compressed air for aeration), a slime-storage vat (whence the slime is taken to the vacuum-filter for washing). The overflow from the settlers and part of the overflow from the filter is sent to the battery-sump and pumped from there to the battery-supply vat, not shown in the drawing.

The solution drawn through the filter passes through a clarifying press on its way to 'strong' and 'weak' gold vats. From these vats it is pumped through a Merrill's zinc-dust precipitation press and returned to the battery-sump. The slime cake is washed first with battery-sump solution and then with water, enough of the latter being used to make up for evaporation loss and loss as moisture in residue.

The labor in this mill to consist of one battery man, one concentrator and tube man, one canvas man, and one cyanide man, together with superintendence, will cost about \$77 per day or 55 cents per ton milled. When the mill is increased to 40 stamps, the labor will be increased by one battery helper and one canvas man per shift, making a total of 36 cents per ton milled.

The slime-plant can be increased largely without increasing the labor required. The slime is transferred from the settlers to the agitators, from these to the filter and discharged from the latter by merely a change of valve settings. Precipitation is effected without the labor required when zinc shavings are used and is quite as complete. As the milling will take place in a dilute cyanide solution, a large part of the extraction will be attained before the pulp reaches the agitators. The battery solution will be kept at a strength of about one pound per ton, the necessary additions of cyanide being made to each charge in the agitators. Enough solution from the battery-sump will be precipitated to keep the value of the circulation solution as low as seems desirable.

The floor of the entire mill will be of cement set with a good grade and will drain into a sump (not shown) in the slime-room. The cost of this plant will be actually less than a sand and slime plant of the same capacity, using decantation and percolation. Labor will be much less, water loss less, extraction better, floor space (and consequently heating expense) less, and power slightly more.

The estimate of power required reaches 200 h.p. It is expected that an extraction of at least 95% will be attained in gold ores averaging \$60 per ton. Total working costs with 20 stamps will be well under \$2.50 per ton and with 40 stamps it is expected that the cost will be less than two dollars per ton.

SUCCESSION OF MINERAL PRECIPITATION.—In the ores of Cobalt, Ontario, it has been ascertained that the smaltite (arsenide of cobalt) was deposited first, closely followed by the niccolite (nickel arsenide); other minerals in small amount were laid down at this time. Then after a period of slight movement, in which the first minerals were more or less fractured, calcite was deposited as a groundmass. Later came argentite (silver sulphide), which was followed by native silver and native bismuth. Lastly came the surface decomposition products erythrite (cobalt bloom), and annabergite (nickel arsenate).—W. Campbell and C. W. Knight, in *Economic Geology*.

Plan and Elevation of a New Cyanide Plant.

Legends of the Desert.

Written for the MINING AND SCIENTIFIC PRESS
By W. H. STORMS.

No portion of the mining region of the West possesses such fascination for the prospector and adventurer as that vast domain lying between the Rocky Mountains and the Sierra Nevada, and southward to the Mexican border. It equals an empire in extent, and though actually a desert, in all that this severe term implies, it supports many thousands of people who lead an active and happy existence, and who derive not only a livelihood, but generally much more—often a fortune—from the wonderful resources of this sterile and little-known land.

Ever since the days of '49, stories of the marvelous wealth of the desert have been carried into the settlements along its border, and into the cities of the Pacific coast. These stories have, in many instances, been the chief, if not the only incentive for men—yes, and women too—to risk their lives on the burning sands of the waterless valleys and amid the rocks of the wind-swept ridges. So full of reality, and promise of fortune are some of these legends of the desert, that it seems little wonder if prospectors are willing to take any risk in the hope of sudden, and comparatively easy, fortune. Each of these remarkable tales describes the finding of wonderfully rich gold rock, or possibly of silver ore, but the finder, for various reasons, was able in each instance to carry away only a few pounds, at most, of the gold-matted quartz, or silver ore, but almost without exception it was a deplorable fact that they were never again able to find the place where the original discovery had been made.

Without doubt these oft-told tales are in a great measure responsible for the discovery and development of many desert mines. Prospectors, upon hearing for the first time one of these fairy tales, would start at the first opportunity in quest of the illusive wealth, and it is a sad fact that to these same stories is due the sacrifice of many adventurous lives, which might have been utilized to better advantage.

One of the most frequently repeated of these extravagant yarns is that of the 'Pegleg' Smith mine. Smith was a frontiersman and squaw man, who had lost a leg in one of his many scrimmages and had substituted a wooden leg for the lost member. He was widely known 50 years ago, in the Southwest, in Arizona and southern California. Although crippled, 'Pegleg,' as he was called, feared not to tackle the desert alone and single-handed. On a certain memorable occasion, so the story goes, being at Fort Yuma or in that vicinity, on the banks of the Colorado river, and wishing to visit Los Angeles, he started with his saddle horse and pack animals across that terrible reach of desolation and death known as the Colorado desert. A sort of road, or trail, was followed by the west-bound pilgrims of those days who chanced to be that far south. This was known as the Butterfield trail. It was partly in Mexico and partly in California. The fact that there was a road, over which hundreds of men, women and children, in wagons, on horse-back, on foot, had traveled, suggests that the trip across the desert, about 120 miles, to the mountains on the west side of the valley, could not be a difficult or particularly dangerous undertaking. Such, however, was, at that time the case, nor is it very much better now. Terrific wind-storms sweep across those plains, obliterating all signs of any roadway that may have existed a few hours before. The coarse sand and small pebbles are driven like chaff before the gale, and good-sized sand dunes are moved from one point to another or are so modified in shape as to be unrecognizable by one who had observed them the previous day. Water, too, is woefully scarce. There were a few

water-holes and springs on the route at that time; of these, Indian Wells was the largest and best known.

Pegleg was well acquainted with the desert and its perils, but undaunted he started for Los Angeles over Warner's Pass, and Temecula cañon—almost a direct line. He estimated that he could reach the little desert stream known as the San Felipe, which flowed in the spring-time from the Cuyamaca range, out onto the desert, in four days of hard travel. The second day out, one of those terrible simoons of the American desert suddenly sprang up, nearly suffocating the venturesome traveler and his animals. The air was filled with choking dust, alkali, and sand, the road-way was quickly drifted full of sand, and for a time progress was almost impossible. Imitating the practice of the Arabs on the Nubian desert, he lay prostrate upon the ground, covering his head with a handkerchief, to keep out the suffocating dust. For hours the storm continued. At times he made a little headway, but realizing that he could not determine the direction in which he traveled, gave it up for a time. During one of the intervals of forced rest the pack-horse strayed away, and when the loss was discovered, and it was possible to travel again, the drifting sand had left no trail, and the crippled prospector was alone with his saddle animal and only a short ration in his saddle bags, his provisions being mostly on the pack-horse. During the night the wind abated and Pegleg moved forward, shaping his course by the stars, as he had done many times before. He was in search of water now, but daylight came and he had reached no spring. His little supply of water in the canteen was running dangerously low. He was surrounded by strange low hills—ridges unfamiliar to him. He finally decided to make for three small buttes, which raised a little above the surrounding hills, and there endeavor to get his bearings, for in this trackless waste the traveler, like the mariner, must steer by compass or by landmarks. After an hour's weary tramp through the deep yielding sand—the most tiresome walking imaginable—he reached the nearest of the three conical little hills. His weary horse he left at the foot of the slope, while he ascended to the low summit. As the sun was rising in the east, far across a stretch of unbroken sand, arroyo, and dry mud lake, he gained the summit of the eminence, and gazed around. He saw at once that he was off the main trail several miles. To the northwest lay Warner's Pass. He studied the low ridges and neighboring hills. Many were mere dunes of sand, others were of rock, as could be determined by their clear-cut, rugged outline. The hill upon which he stood was of rock, blackened, and burned by the fierce desert sun, but presenting little of variety. It all looked black, all was coated with that peculiar gloss familiar to the desert traveler. Light-colored rocks and dark, look alike here. With the instinct of the prospector Pegleg glanced around, and knocked off a few chips from what appeared to be a dike or vein. A single look showed gold—a mat of gold in a bluish-black quartz; feverishly he attacked the ledge; pieces were spalled off from a score of places, and gold showed everywhere. He could hardly believe his senses, but the evidence was indisputable. Here was the vein and in it the gold—such ore as he had never seen before, nor dreamed of. Pegleg was a practical man. He had seen enough to satisfy him; delay was dangerous; he knew that to return later would be easy. At the time he was wholly unprepared to do anything with his discovery, his only fear being that some other might find it. He realized his physical condition, and the scarcity of the water upon which his life depended. His horse was weak, indeed, dying, for the simoon produces a raging thirst in both man and beast. He must leave this newly-found fortune and hasten on to Los Angeles as rapidly as

possible. He at once descended the hill, taking all the ore he could conveniently carry, and this he placed in the saddle-bags. Mounting, he rode slowly to the northwestward headed for Warner's Pass, still many dreary miles away. On and on, hour after hour, he rode or walked, hoping to again strike the trail. His water was now exhausted, his horse no longer able to carry him, and each moment growing weaker. The sun had become a blazing metallic ball suspended in an atmosphere of crystal. Every object viewed across the desert plain was distorted by the radiant heat of the sand. The half-crazed prospector saw, only a mile beyond, fields, beautifully fresh, and amid them a pelucid stream, delightfully blue, and fringed with trees of living green. What a glad sight to both man and horse. Poor Pegleg! To him it was only added torture, for by similar experience he had learned long since to recognize that lure of the desert—the mirage. He knew that where appeared green fields was nothing but sagebrush and griswood—the river, a phantom. He made haste, however, as rapidly as possible, stumbling, falling, crawling. Sharp poisonous thorns of the cholla cactus penetrated knees and hands; he was indeed a pitiable object; nor was his horse in better condition.

At last, when he was about to give up all hope, he recognized some neighboring ridges with their yuccas, and knew if he could only reach them he might obtain water. How gladly would he have given his mine of gold for only a canteen-full for himself. Late in the afternoon he reached a small spring, a short distance from the traveled emigrant trail. He and his horse drank deeply, and after resting until nightfall they set forth once more toward the Cuyamaca mountains, looming darkly in the west. They seemed very near just before night, but it was still many miles to their base.

Painfully Pegleg slowly advanced, and in time he reached the San Felipe and Warner's Pass, and a few days later, Los Angeles. During his journey through the more settled portion of the country not a word of his discovery did he breathe—he dared not—for the merest hint of what lay out on the summit of that low desert hill, would, he knew, send every man in southern California, who could possibly go, stampeding into the wilderness beyond the Cuyamacas.

When Smith reached Los Angeles he was very ill. He took a room at a small hotel, carried his saddle-bags into his room, tossed them under the bed, sent for a doctor, and went to bed. From this bed he never got up. Exposure, hardship, nervous excitement, and old age, each aided in breaking down the hardy desert pioneer. Realizing that his end was drawing near, Pegleg asked the doctor to pull the saddle-bags from beneath the bed. He did so, and drawing forth the golden pile of rock, he looked in astonishment at the man and the ore. Smith, rapidly sinking, laboriously told of his discovery. The sandstorm; the three hills; the gold; the mirage; the battle with thirst; and the final reaching of his destination. "I can't pay you, Doc," said Smith. "I'm going. Take the mine—she's yours. About 30 miles from Smith mountain, southeast from Warner's Pass, and south of the Butterfield trail." Smith died, and left this legacy to his friend, the physician who had attended him.

This is the story of the Pegleg mine as it has been told and re-told a hundred—perhaps a thousand—times in the mining settlements and about the prospectors' camp-fires of the Southwest. Hundreds of men have searched diligently for the Pegleg mine, but it has not been found, nor do I believe it ever will be, for in my opinion it is a fabrication, pure and simple. Started as a newspaper yarn of half a century ago, it has been repeated with

many variations and modifications until many have believed in it implicitly. It is no exaggeration to say that not less than a score of brave but indiscreet men have laid down their lives in the pursuit of this will-o'-the-wisp. I knew personally five men who died on the desert of the Colorado, and one who lost one of his hands and an eye by explosion of nitro powder—all in search of the ill-fated Pegleg mine. Nor has the search been abandoned. Each year still sees men go forth silently into the desert from the cities of southern California to look again for the mine that has no existence.

About the year 1861, a party was slowly wending its weary way across the desert through southwestern Nevada, not far from the California line. Water was short and in the hope of seeing some indication of water, one of the party, a man named Breyfogle, left the caravan and climbed up a neighboring hillside. He did not find water, nor see any sign of any, but he did find a quartz ledge, glittering with dull gold. He looked carefully about, took his bearings, hid a few small pieces of the wonderfully rich ore in his pockets, and returned to the wagon train. He said nothing of his discovery, for he was 'at outs' with the members of his party. Indeed, all were at outs, each with the other, for travel across the desert, hundreds of miles, had made each man a sordid selfish animal, ready and eager to take any personal advantage of his companions, if it would in a small degree relieve himself of hardship, privation, and responsibility.

After weeks of toil, loss and illness, the party reached San Bernardino, and eventually Los Angeles. Breyfogle made public his discovery, and considerable money was subscribed to outfit an expedition to locate the Breyfogle mine. The fortunate discoverer returned as a guide with the party, but when he reached the Death Valley region near which the find had been made, he was unable to again find the ledge from which he had broken the rich specimens. For days the members of the party searched, but in vain. Finally, concluding that they had been deceived, the angry men decided to give Breyfogle short shift, and informed the unfortunate prospector that he would be given a few minutes in which to settle accounts with his Maker. Breyfogle walked slowly up the hillside, leaving his scowling, muttering companions to decide upon the manner of his death. Overcome at the sorry fate which had overtaken him, he sat down upon a ledge of rock. Chancing to glance at the rock he saw numerous colors of gold. "I've found it, boys!" cried Breyfogle. "Here is the ledge." All rushed to the spot, and, sure enough, here was a quartz vein rich in gold. Locations were made, and eventually considerable gold was recovered from the mine, but few—not even Breyfogle himself—believe that it was the same vein that he had discovered before. It is said by some that the Montgomery mine is where Breyfogle made his original discovery. Others say it was at Bullfrog. As to this I am unable to say.

Some years ago I was one of a party that set out to search for a 'lost mine,' which still remains lost. A well known miner and prospector of the city of San Bernardino, California, had in his home a cabinet of minerals. One day a friend, looking over the collection, picked up a piece of heavy black ore, and asked with interest where it came from. After regarding the rock for some time silently, the owner said: "O yes, I remember this ore. We found it out on the desert four or five years ago."

"Do you know where?" inquired the friend.

"Yes," replied the other. "It was on the edge of a dry lake, not many miles from Rabbit Springs. Is it any good?"

"Good!" said the friend, "well, rather! It's almost

solid horn-silver, worth anyway \$6,000 to \$8,000 per ton."

The matter was carefully talked over, a sketch map made, and a four-horse outfit with four men, tents, tools, provisions, and every essential might soon have been seen going up the Cajon pass, headed for the Mojave desert. They searched for days, but unsuccessfully. Three seasons in succession, they looked, but in vain. They finally gave up the quest, and the map came into the possession of a friend of mine. Having business on the desert at Silver Reef, a few miles from Rabbit Springs, we decided to look for the lost mine, in the vicinity. By aid of the sketch map, and joined by two other men, we searched the hills and found every detail as described by the original discoverers, but instead of horn-silver we found only black tourmaline.

The conclusion reached was that the owner of the cabinet had become confused in his identification of the original sample, which had come from some other region.

Each important desert locality has its own lost mine. On the Colorado desert it is the 'Pegleg' mine. In the Death Valley region it is the 'Breyfogle,' or the 'Gun-sight.' On the Mojave river, it is the 'Lee mine.'

Lee was an old, erratic German prospector, who owned claims all over the desert. He was supposed to have located a vein in which the native silver cropped out on the surface in abundance. Although there are plenty of descriptions, and bearings, yet the Lee mine remains undiscovered, probably because, like the Pegleg mine, it never had an existence. Curiously, however, Lee had among his numerous locations one he called his quicksilver mine. This was situated about four miles north of Barstow, and about three miles from the Mojave river. Although the rock was various bright shades of mineral red, due to abundant hematite, there was not a grain of quicksilver in the entire hill. Lee did considerable work on this prospect, but appeared to attach no particular value to it, preferring, when rustling for a stake in San Bernardino, to talk of his 'white metal' mine—the one which no one has ever been able to find.

One day 20 years or more ago, Lee was found dead near Old Woman's springs, with a bullet hole through the back of his head. His 'quicksilver' mine was jumped by men searching for the lost Lee mine. It eventually proved to be a rich silver mine from which several millions of dollars have been taken.

The desert teems with story and romance. Many fortunes have been made there, in gold, silver, copper, lead, borax, salt, and other minerals, and far more doubtless remains to be taken from the mines, but no story yet told of early days and lost mines has eclipsed, or even equaled, the richness of some of the deposits found in the Goldfield region of Nevada. No one of the desert romancers, who play upon the credulity and cupidity of merchants and others in the cities, has yet dared to represent having found anything one-half as good as was discovered during the first year at Goldfield. Nevertheless, the fairy stories of the desert have been an important factor in the development of that region, and we may expect to hear of many more 'Lee' and 'Pegleg' mines, and possibly of other Tonopahs, and Goldfields, and Bullfrogs. The desert will long remain incompletely prospected.

A MIST OF WORDS, like halos round the moon, though they enlarge the seeming size of thoughts, make the light less, doubly. It is the thought writ down we want, not its effect, not likenesses of likenesses; and such descriptions are not more than gloves, instead of hands to shake, enough for us.

REAL knowledge in science means personal acquaintance with the facts, be they few or many.

Experiments With Lava From Vesuvius.

*The author had the opportunity, in April, of seeing the place on Mt. Vesuvius where, only a short time before, the great outpouring of lava occurred, and later he examined the new fields of lava at Bosco tre Case and Torre dell'Annunziata.

Both places showed a number of 'fumaroles,' or smoke-holes. Vapors arose from numerous cracks and crevices, and delicate deposits were being formed at the edges, before the very eyes of the observer. On the volcano itself, these deposits were yellow to orange in color and consisted mainly of alkali and iron chlorides. Below, near Bosco tre Case, the sublimates were chiefly white, consisting of ammonium and sodium chlorides.

On the mountain the steam from the 'fumaroles' frequently contained hydrochloric acid, as readily perceived by the odor, and occasionally even the smell of free chlorine was observed. At another place sulphuretted hydrogen occurred and there was evidence of sulphur dioxide. Below, the vapors consisted mostly of steam. Hydrochloric acid was rarely noticed, while free chlorine was not observed at all.

The present theory of the formation of these 'fumaroles' is as follows:

When the volcanic magma leaves the crater, it is highly charged with steam and gases. These escape during the cooling process, as the conditions of pressure, etc., change. The basis of this theory is apparent, for the upper parts of cooled lava are porous and spongy from the bubbles of escaping gases. Among these, aqueous vapor predominates, but hydrochloric acid is nearly always present, and probably vapors of sodium chloride and other volatile substances. Direct proofs of the last assertion are still lacking, however.

These vapors at first escape rapidly, often causing explosions; then more slowly and finally they cease altogether. Fumarole activity begins when the explosions have stopped and the gases escape quietly and regularly. The products of the fumaroles are the same as come from the crater itself. The present theory maintains that all the substances produced by the 'smoke-holes' are present in solution, *already formed* in the volcanic magma.

It was observed by the author while examining the lava near Bosco tre Case, that some places showed considerable fumarole activity, but others, where the conditions of heat, thickness of the lava-bed, etc., were apparently the same, showed none. For instance, no 'smoke-holes' were to be observed where the lava had filled a railroad cut, while close-by, in a ravine, they occurred in great numbers. In the cut the lava lay on a prepared and therefore comparatively dry bed; in the ravine it covered vegetation (to judge from the vicinity) and damp ground, for a lake was not far distant. Doubtless the lava vaporizes the moisture gradually, which then forces its way upward through crevices in the hot mass. To determine whether steam decomposes lava, causing the fumaroles, was made the subject of experiment.

Natural conditions were readily imitated on a small scale, with the following results: Pieces of lava were washed until they gave no chlorine reaction with silver nitrate, dried and placed in a combustion tube. The tube was then heated, strongly in the middle, less at each end, and a current of dry air passed over the lava. A little water showed first, and after about three hours a faint, bluish-white sublimate appeared. The water gave only slight traces of chlorides and was carefully removed along with the sublimate. A current of moist air was then passed through, and in less than half an hour

* Translated from the *Zeitschrift für Angewandte Chemie*.

sodium chloride, solid and in solution, appeared in such quantities as to give a strong reaction.

A second experiment with washed lava gave water and a white sublimate after heating two hours. On removing the deposits and continuing the heating another hour a second faint white sublimate was obtained, but no iron showed. On passing moist air containing hydrochloric acid, crystals of ferric chloride began to form after a few minutes in the cooler portions of the tube, and at the same time there was a strong smell of chlorine.

The formation of chlorides is readily explained, since it is seen that water and hydrochloric acid decompose lava, but the production of chlorine is not so easy to understand. It might be due to oxidation of hydrochloric acid by the lava, to decomposition of ferric chloride or to oxidation by air. To determine which occurred, lava was heated in a current of dry hydrochloric acid gas. Ferric chloride sublimed, traces of water appeared, and a very faint odor of free chlorine was perceived. On substituting moist hydrochloric acid, the results were unchanged, but as soon as air was admitted the chlorine increased considerably.

Cutting out the air again, the chlorine almost ceased.

This experiment could be successfully repeated as often as desired. When pure ferric chloride was treated with dry or moist hydrochloric acid, under otherwise identical conditions, the smell of chlorine was barely perceptible and less than in any of the former experiments. The formation of chlorine is, therefore, only in very slight degree due to the dissociation of ferric chloride. More is produced by the action of lava on hydrochloric acid, but the chief source is the oxidizing action of the air. It is also possible that catalytic processes are at work.

The circumstance of water-vapors, alone or mixed with hydrochloric acid and air, passing through hot lava occurs frequently in nature. Both water and hydrochloric acid can originate in the volcanic magma, or the water may have its source in moist ground upon which the lava rests. The products of sublimation are therefore not necessarily all present in the lava as such, but must be produced, in part at least, by the action of aqueous and hydrochloric acid vapors on the magma. When steam alone is present, white sublimates occur, while hydrochloric acid gives colored ones containing iron. If both are accompanied by air, there is formation of free chlorine.

Thus certain observations, formerly looked upon as insoluble riddles, are easily explained. For example, J. Roth said in 1857:

"On closer study of lava much is observed that is difficult of comprehension. Among other things there is the slow, but considerable evolution of volatile matters.

Some of these substances are vaporized at comparatively low temperatures, such as water, hydrochloric acid, ferric chloride, etc., while others, like sodium and potassium chlorides, require much more heat. All these should be found in greater quantity in fresh lava than in the older whose surface is already 'frozen.' Their evolution from fresh lava also seems not to last very long. The lava's viscosity might account for the retarding and long continuing sublimation, but the elasticity of the substances—gaseous at 212° F. or little above—must be very great at the high temperature of the lava. On breaking up lava three miles distant from Vesuvius from the eruption of 1767 for road metal, its interstices were found encrusted with crystals of hematite.

Therefore ferric chloride was not only contained in the lava at this distance, but it was *formed* when the lava had cooled so far that it had begun to crack. * * * The lava from the last eruption shows that evolution of volatile matters increases after solidification has begun. The

increased development of steam cannot be ascribed to rain falling on the lava, for it did not coincide with the rainy weather and the new fumaroles, formed after the lava had ceased, either emitted no water-vapor at all, or else it was mixed with other substances. The products were mostly sodium and potassium chlorides, which require a very high temperature for their vaporization. This was most evident in Fosso della Vetrana and at the ruined bridge between San Sebastiano and Massa di Somma, where the exhalations immediately after 'freezing' of the lava were considerably less than they were a month later. In Fosso della Vetrana evolution of gas only began toward the end of June and beautiful salt-crusts were still depositing early in November. The opening was covered with a large piece of lava on September 25, and was encrusted in less than two days with salts five-sixteenths of an inch thick."

If it is assumed that lava flowed over moist ground or such as became moist through later rains, and there was hydrochloric acid present, the observations formerly so hard to understand, are at once explained as the effect of secondary chemical action of water and hydrochloric acid on lava.

The theory of the formation of fumaroles is to be extended as follows: In this natural process mechanical expulsion of already formed alkali and iron chlorides does not necessarily occur in every case, but these chlorides are produced secondarily under certain chemical conditions by the action of water and hydrochloric acid gas on hot lava. In which cases mechanical or chemical processes occur separately and alone or together, can only be decided by further observation and experiment.

NUMEROUS IRON OBJECTS of prehistoric date have been found in northern Europe, where iron was undoubtedly the first metal to be used. Iron weapons, too, have been found in the remains of pile dwellings in Switzerland. In that country the Bernese Jura abounds in remains of prehistoric iron smelting, which have been carefully investigated by Quiquerez, a scientifically trained mining official. The furnaces were in dense forests, in order to obtain an easy supply of wood. The workmen dwelt in caves, and charcoal was burned in piles. The furnaces were all similar, differing merely in size. On the natural ground, with no foundation, the hearth of firebrick was laid. Lumps of the same material formed the walls, which were supported externally by dressed stones filled in with earth. Two inches above the hearth a channel was left open, which had the entire width of the hearth, was arched over, and widened out at the exterior. It was made of fire-clay, the aperture consisting of several large stones which were covered with a stone slab. The shaft of the furnace was cylindrical, and inclined toward the top, so that charcoal and ore would pass down on one side, leaving the other free for the air-current. The shaft was eight feet high, and the top was surrounded by a circle of stones. The furnaces were charged from above. The air entered at the base, no bellows being used. The opening at the base thus served as a tuyere, slag-hole, and discharging hole for the blooms, which were from 30 to 50 lb. in weight. At several of these prehistoric furnaces flint implements were found, showing that the Swiss iron industry dates back to the storage, before bronze was introduced by foreign merchants.

If it were possible to have all the phenomena of the past presented to us, the convenient epochs and formations of the geologist, though having a certain distinctness, would fade into one another with limits as undefinable as those of the indistinct and yet separate colors of the solar spectrum.

Prospecting With Churn Drills.

Written for the MINING AND SCIENTIFIC PRESS
By F. S. PHEBY.

Believing that the great horizontal orebodies of the Ely district could be more cheaply and expeditiously tested by the use of the drill rather than through the usual tedious and expensive method of shaft-sinking, the Ely Central Copper Co. purchased two drills, manufactured by the Keystone Drill Co., of Beaver Falls, Pennsylvania. These drills were hauled from Cherry Creek to the mines, a distance of 60 miles.

These machines are type No. 3 and weight 12,000 lb. each. A complete outfit of tools and equipment for recovering any parts of the drills lost in boring the holes, were included in the order.

The first drill was installed on the property in August and we had a hole completed to a depth of 308 ft. within 23 days, although but one shift was engaged in this work. It is far more economical in wood and water to keep the drills running continuously with three shifts. More than three times the sinking can be done in the same number of days, as steaming up in the morning generally comes out of the one shift. The drill averaged 13.3 ft. per shift for the 23 shifts, but if shut-downs are deducted, the drill averaged 19.6 ft. per shift of actual operation.

We have found in all our work that casing is necessary in every hole. At times we have sunk 200 ft. without casing, but to go deeper casing was necessary, which meant that the hole had to be rimmed out at an expense of more than the original cost of the hole for the 200 ft. I caution anyone contemplating the purchase of a drill, to provide 7½ casing for one-third the depth contemplated, 5½ casing for two-thirds the depth, and 4½ casing for full depth. This we had not done, and probably 25% has been added to the cost of each hole, working without sufficient casing. Trouble may not be encountered in several hundred feet, but a soft stratum of ten feet will require the casing for the entire hole.

We soon learned that the wear and tear on the drilling cable was severe. Under ordinary circumstances, each rope is safe for 1,500 ft. of drilling. When we appreciated that our ropes were deteriorating, an order was placed at once. By October 1 the cable had not arrived, and we were compelled to order by express from Ohio a coil of rope weighing 1,850 lb. With each drill, two ropes of the same length as the depth of the hole contemplated should be ordered.

Water is required for both the boiler and for diluting the drillings so that the sand-pump may bale them. The greater quantity is required for the boiler. This item of expense is local with each hole. It is advisable to haul water in a good wagon-tank, as the drills may be moved many times, and the cost of pipe might be greater than the cost of hauling. A drill-man and helper are required on each shift; the former receiving \$4 for eight hours' work and the latter \$3.25. The item of fuel and water is wholly relative, but will be given in our particular case, and may be taken as an average for this district.

The following is the tabulated costs for a certain hole which we have taken as an average :

Shifts of sinking (eight hours each).....	23 days
Depth of hole.....	308 ft.
One drill-man, wages.....	\$ 82.69
One helper and assistance while handling casing.....	81.08
¾ cord of wood each shift, at \$4.50 per cord.....	77.51
12 bbl. water at \$6.50 for hauling, 8 days.....	52.00
12 bbl. per day (when running two rigs), 15 days.....	48.75
Coal and oil.....	7.60
Miscellaneous charges.....	12.20
Superintendence.....	50.00
Cost of 308-ft. hole.....	\$411.83
Cost per foot.....	\$ 1.33

Some water was encountered in this hole, and I may say roughly that a two-compartment shaft for the same depth with equipment, would have cost about \$12,000, or \$40 per foot.

The question has often been raised concerning the character and accuracy of the sample obtained from this work. With small rich veins there may be an objection to the use of drills, but in orebodies like those found at Ely, I believe as good a sample can only be taken with great care. Most of the sludge or drillings will pass a 20-mesh screen, and a good method is to provide a large box with a capacity equal to several screw-lengths. I might say that a screw is three feet long, and when fed out, the clamps are changed on the rope, and the hole baled, or sand pumped. By settling and decanting the water, the entire product of the hole may be saved and sampled. In ordinary practice it is sufficient to dip a sample from the box and pour the same into a box partitioned off in compartments about the size of common brick. This sample, when dried in the sun, is compact enough to be sampled by chipping, and can be shipped and carried about without breaking.

In a hole carried down without casing, there is danger of knocking down particles from the upper portions of the hole. This will vitiate the sample, but the harm done is more theoretical than actual. As is well known, the orebodies of Ely are the impregnation of a great stockwork of porphyry, and an orebody of much value must be a hundred or more feet thick. While actually in ore, the sampling must be done with extreme care, but often the hole, all or in part, may be in barren country rock, and only a knowledge of the formation penetrated is desired.

The best test, where not in ore, is obtained by panning the sample. This concentrates the coarse particles, which are clear to the eye if a magnifying glass of low power is used. In oxidized formations some doubt often arises as to whether the drillings are composed of porphyry or limestone. A small bottle of dilute hydrochloric acid will soon settle this question with entire satisfaction. We have made a practice of saving a sample of each formation penetrated, in four-ounce bottles. This gives a clear picture of the hole, and is valuable for future reference.

Our drills are provided with traction gears, and may be moved at will over the roughest ground. This saves the expense and trouble of procuring teams. The winter weather is severe for outside work, and sectional houses, so made as to be readily knocked down and moved, have been constructed to enclose the drills, and within these houses the men work in comfort.

The cost of a No. 3 drill is as follows :

Drill f. o. b. Beaver Falls.....	\$1,400
Cost of casing for 400 ft. and fishing tools.....	350
Freight to Cherry Creek, Nevada.....	328
Hauling 60 miles from Cherry Creek.....	225

Cost of No. 3 drill, good for 500 ft., laid down on the ground.....\$2,303

A drill of this size is light for holes of greater depth than 500 ft. The size recommended is a No. 5, good for 1,200 ft., and the cost of the same with traction gear, is about \$2,500 laid down at Ely. Should five holes of 500 ft. each be sunk, the cost of equipment per hole will be \$500, about the price of a good whim outfit. The cost of \$1.50 per foot is so much cheaper than any shaft work as not to be comparable. Water does not retard the work of drilling; in fact, it is a benefit.

I can heartily recommend the use of three drills for prospecting in this region. Apart from the cost per foot, the time in which a good working knowledge of the ground can be obtained, is a great factor. The sample is quite as good as a core, and most ground can be penetrated at 25% of the cost incurred with a diamond drill; while the expense of equipment will not exceed 30% that of the diamond-drilling outfit.

A Profitable Syncline.

Miners are familiar with the occurrence of gold ore in the form of saddles or anticlinal formations of quartz, both at Bendigo, Australia, and in Nova Scotia. It has been reserved for New South Wales to furnish an example of an inverted saddle or syncline of rich goldbearing quartz. Such is the deposit at Mount Boppy, situated about three miles off the Nyngan-Cobar railway. The district had been mined for copper for a great many years, but it was only six years ago that gold was found. For the last three years Mount Boppy has become prominent, by reason of the profitable operations of an English company, and a town of 1,500 people has sprung up. The mine is the largest gold-producer in the State, the ore averaging 12 dw't. per ton. In the Annual Report of the Department of Mines it is stated that "payable ore has been found on the upper levels of the mine for a distance of 1,300 ft. The orebodies vary in width from 6 to 50 ft. If the longitudinal section be referred to, the stipes in the northern end of the mine will be seen to terminate in their downward extension against the so-called 'slide.' The term 'slide' is a misnomer and misleading. We have here not a line of faulting, but a natural plane of parting between the ore and the country along the bottom of the saddle or synclinal fold. The so-called new make of ore upon the west is nothing more than the western leg of an inverted saddle, of which the main lode is the eastern leg. The structure of the ore deposit will be more clearly understood after reference to the accompanying ideal plan, and longitudinal and transverse sections, and also the actual sections taken across the reef. The curved base of the saddle reef can be well seen at the 200, 300, and 400-ft. levels respectively. It is met with in the 130-ft. level at a point 360 ft. north of the main shaft, and in the 400-ft. level at a point 400 ft. south of the main shaft. So it would appear that it pitches southward at a high angle. A glance at the longitudinal section will show that the angle varies between the different levels of the mine. It will probably be found that the whole orebody pitches south with the syncline, and a correct appreciation of this fact should have a most important bearing upon the efforts which are being made to pick up the lode beyond the existing workings.

The legs of saddle reefs do not extend downward, or in the case of an inverted saddle upward, for an indefinite distance, and it is quite likely that owing to the southern pitch of the syncline, the legs of the reef may at this point be considerably more than 100 ft. below the surface, and the main body of the ore, which rides in the trough of the syncline, at a depth of several hundred feet. Indeed,

the disappearance of the reef in the southern end of the upper levels may be due to the pinching out of the legs, and it will probably be found that as greater depths are reached and the bottom of the syncline approached, the lode will extend farther and farther to the south. It would appear, if the lode be continuous and the pitch of the main body of the ore does not materially alter, that it must pass right under the cross-cuts.

In this connection I should point out that the length of the legs of a saddle, or the distance they extend from the cap of the syncline or anticline, as the case may be, is liable to differ for each leg and to vary considerably along the same lode. For instance, in the case of the Great Broken Hill silver-lead lode, using the cap of the saddle as a datum or starting point, the western leg seldom if ever extends more than 100 or 200 ft. downward, while

the eastern leg (which has in at least one place been found to give out altogether at 300 ft.) has been proved in other places to extend over 700 ft. At Mount Boppy there is evidence to indicate that the western leg is not so persistent as the eastern. Again, a lode which may have the normal outline of a saddle throughout the greater portion of its length may in some cases, owing either to the action of conflicting forces at the time of, or subsequent to its formation, be distorted almost beyond recognition. This is noticeable in some places at Broken Hill, and the section through the main shaft shows how the Mount Boppy reef has been distorted at this point.

The oxidized ore is composed essentially of quartz, with a small admixture of oxide of iron, and the unoxidized ore of quartz with iron and

arsenical pyrite, galena, and zinc-blende. Gold is always present in an extremely fine state of division. The ore hitherto treated only contained insignificant quantities of copper, and this remark applies also to the unoxidized ore now being raised from the lower levels as well as to the oxidized ore. It is on this account that the ore from Mount Boppy has proved far more amenable to treatment than that from certain other mines in the Cobar district."

THERE is no study better fitted than that of geology to impress upon men of general culture that conviction of the unbroken sequence of the order of natural phenomena, throughout the duration of the universe, which is the great, and perhaps the most important, effect of the increase of natural knowledge.

It should never be forgotten that what we call 'catastrophes' are, in relation to the earth, changes, the equivalents of which would be well represented by the development of a few pimples, or the scratch of a pin, on a man's head.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

A lease of mining property stipulated that the lessee should comply with the laws of the State, and surrender the premises at the end of the term in good condition as an entire mining property. At the time of the surrender of the lease, there was water in a portion of the mine, and there was no escapeway except a shaft sunk by the lessee on adjacent property. The lessee, at the end of the term, surrendered the premises as an entire mining property exclusive of the escapement shaft as constructed by him on the land of another. In passing upon the rights of the parties at the time of the surrender, the Court decided that the lessor, though bound to pay for permanent improvements constructed by the lessee, was not required to pay for the escapement shaft; that not being entitled to an escapement shaft and an escapeway to constitute the premises an entire mining property, a decree requiring the lessee to pay the cost of removing the water and the cost of removing obstructions in the escapeway was erroneous, as the statute only required an escapement shaft, or an escapeway, but not both.

Junction Min. Co. v. Springfield &c. Co., 78 N. E. 902.

A lease of a coal-mining property for a fixed term gave the lessee the exclusive right to mine on the property, bound him to take the premises as an entire mining property, to mine and sell the underlying coal as speedily and in as large quantities as possible, to pay the lessor a royalty on the coal mined, to quit the premises at the end of the term in good condition as an entire mining property, and bound the lessor to purchase the property of the lessee then on the premises, and pay for all the improvements of a permanent character made on such premises by the lessee. In a controversy of the rights of the parties at the end of the term, the Court decided that the lease contemplated that in the operation of the mine by the lessee, some of the personal property on the premises at the beginning of the term would be worn out by use, and that the lessee would substitute therefor new property and fixtures and would from time to time provide additional property and fixtures necessary for the operation of the mine, and make permanent improvements; and for all of which the lessor must compensate the lessee at the end of the term. But the lease did not require the lessee to rebuild worthless buildings that were destroyed by fire without any fault of the lessee, they not being necessary to constitute the premises "an entire mining property." The lease also prohibited the lessee from mining and taking coal from other than the demised premises. But the lessee did mine coal from other lands with the knowledge of the lessor and without any protest from him and the lessor received and accepted the royalty on the coal thus mined from other premises with full knowledge of this fact. The Court decided that the lessor was not entitled to damages for the violation of the covenants of the lease against mining on adjacent property.

Junction Min. Co. v. Springfield &c. Co., 78 N. E. 902.

The statute of Pennsylvania makes it a misdemeanor for anyone to engage as a miner in any anthracite coal mine, except he first obtain a certificate of qualification and has been duly registered to engage as a miner in any anthracite coal mine. As a qualification for such certificate the applicant shall have had two years' experience as a miner or mine laborer in the mines of that Commonwealth. In placing a construction upon the statute, the Supreme Court of Pennsylvania decided that the act should be construed so as to require two years' experience in the anthracite coal mines of the Commonwealth, and as thus construed it was not unconstitutional as contravening the Constitution of the United States in respect to the privileges and immunities of citizens.

Commonwealth v. Shaleen, 64 Atl. 797.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The rock sent by P. H. McM., of Randsburg, Cal., is a biotite gneiss.

The small pieces of slate sent by S. T. P., of Palisade, Nev., are not oil-bearing.

Specimens from Paris, Cal., marked E. F. E., are: No. 1, Schist, containing pyrite; No. 2, Rhyolite; No. 3, Melaphyr; No. 4, Rhyolite-tuff; No. 5, Limestone.

Samples from Homestead, Ore., marked M. R., are: No. 1, Limonite and quartz; No. 2, Silicious rock with hematite and serpentine; No. 3, Pyrite in quartz; No. 4, Talc schist; No. 5, 6, and 7, silicious rock, mainly quartz stained green with chlorite or serpentine.

A Strange Clean-up.

Not long ago, the Bonanza Basin Gold Dredging Co., operating an Allis-Chalmers gold dredge in Alaska, reported the finding of a perfect specimen of magnetic iron ore, or lode-stone, in the clean-up. Although, from its unusual size, the specimen referred to was remarkable, it seems that a still more curious find was made recently by the same dredge. When the long sluice-box was opened recently, preparatory to the periodical clean-up, it was found that the bed of the slough which had just been worked, had yielded an assortment of stuff, the equal of which has never before been seen in Dawson or elsewhere in the mining regions of the West. The collection disclosed, among other things, two Russian bronze ikons, which had probably been carried into the region by Russian explorers many years before the Klondike was heard of. The ikons were identical with those carried by some of the regiments of the Czar's army in the recent Japanese war. Besides the ikons were found eight American pennies, probably thrown into the slough by some prospector in a fit of disgust when he realized that they possessed no purchasing power in the Yukon district. There were also recovered about 100 lb. of unexploded cartridges, gallons of bullets, many of which had a coating of amalgam, which necessitated their treatment for the gold adhering; 120 lb. of nails of all sizes; an alarm-clock; a saw set; two masonic gold charms; an opal with its setting from a broken scarf-pin; innumerable pieces of watch chains; knives, forks, keys, locks, native bismuth, cassiterite, stannite, bushels of black sand, and a number of nuggets worth over \$10 apiece. The last item caused some surprise, as it had been generally understood that the gold in the basin was of a fine quality. The dredge, which is now in winter quarters, has been in operation all summer.

RAILROAD BUILDING in Mexico proceeds vigorously. The Southern Pacific is building a line from Guaymas to Mazatlan and thence to Guadalajara, where connection will be made with the Mexican Central. This road, however, will not prove of such immediate benefit as expected to the mining districts of Durango, because it will hug the coast, and not until spurs are built to the separate districts will they get the facilities needed. The International railroad, that stretches from Eagle Pass through Torreon to Durango, is also to be extended to the Pacific coast at Mazatlan and this will help mining in Durango. Furthermore, a new railway is planned between Tucson, Arizona, and Port Lobos, on the Gulf of California.

The Cause of Air-Blasts in the Mines at Pribram, Bohemia.

BY HUGO STEFAN.

*Stresses in the country rock may develop from chemical as well as from mechanical causes, although in the case under discussion the latter alone are of importance.

Assuming that there be at any point in the earth's crust a strain such as would tend to buckle the rocks in which it occurs, it will vary in its effects according to the physical characteristics of the different strata; thus, mild and plastic clays will behave very differently under tension from harder and more brittle coal. Conditions prevailing near the surface, moreover, are different from those at great depths. If the buckling force is brought to bear on a rock stratum at great depth, the direction of the movement taking place in the folding of such a layer will be opposite to that in which the force of gravity acts on the rock. Near the surface of the earth equilibrium of these stresses has long since been established, partly because the original superincumbent strata have been removed by denudation or else because deep weathering or disintegration has loosened the ground and so allowed it to yield readily. As long as any bed in a formation maintains its solid relationship to others, it is in a position to withstand much greater forces than after having been disturbed or loosened.

When the equilibrium of layers of rock is disturbed by

underground workings and sudden changes of strain are produced, breaks may occur with irresistible force, frequently resulting in the phenomena termed 'air-blasts.' In support of this statement the following paragraph may be cited from F. R. von Hauer:

"Interesting observations on what may be termed a latent pressure to which beds of rock in their natural position in the earth's crust are sometimes subjected, and concerning the sudden breaking apart of such beds, have been published by Professor Niles of Boston. He noticed in a number of quarries in the United States that on loosening large sheets of rock from their original position, they underwent considerable expansion. Actual measurements showed an increase in length of at least one in a thousand. It appears that this expansion occurred in a north and south, not in an east and west direction. In a limestone quarry at Lamont, twenty miles south of Chicago, on stripping off the surface, an underlying stratum of rock was exposed, which afterward buckled slightly, forming a wave-shaped crest or anticlinal, the ridge of which extended east and west for over 800 ft. The height of the anticlinal was 6 to 8 in. and its width about 18 ft. Later on a longitudinal fissure formed with a loud explosion along the crest of this fold. The buckling was evidently the result of a horizontal pressure, in a north and south direction, to which the strata yielded as soon as their overburden had been removed."

*Translated for the *School of Mines Quarterly* by C. R. Corning from *Oesterreichische Zeitschrift*.

Aside from chemical processes, therefore, the cause of air-blasts may be assumed to be mainly a combination of several factors: (1) The composition, structure, and cohesion of the rocky strata. These present varying resistance to pressure, together with conditions permitting the equalizing of internal strains. (2) Depth below the surface. Here the weight of the overburden of rock tends to prevent the stress from being relieved by buckling. (3) The advance of surface weathering, if very extensive, produces elasticity in the overburden, which is then easily forced aside or upward by any tendency on the part of underlying formations to form anticlines.

At Pribram a number of silver and lead veins are worked. They are frequently associated with greenstone and diabase dikes. These veins dip from 70 to 90° east or west, and run approximately north and south in a syncline of Cambrian sandstone from 2 to 3½ kilometres wide. The northwesterly slope of this syncline dips 80°, while the southwesterly side is flat. The Maria shaft is 350 m. west of the bottom of the syncline. At a depth of 1,009 m. (the thirtieth level) the shaft is within 40 m. of this syncline and cuts it at the thirty-second level at a depth of 1,009 m. where a vertical fault-fissure traverses the horizontal strata so that east of this fissure the beds are 25 cm. below their position on the western side. The course of the fault-fissure is nearly at right angles to the sandstone strata. In the easterly and lower strata there are a number of calcite stringers up to one centimetre thick, traversing the strata and starting from, but younger

than, the fault-fissure itself. The individual beds, which often pinch out, vary greatly in thickness as well as in structure and composition. Hard silicious graywackes alternate with clays, both fine and coarse-grained, in dense schistose layers.

The diabases, which are an important element in the structure of the formation, have, when fresh, much of the hardness of feldspar; when, much altered, they are soft. It is evident that the squeezing of the rocks incidental to the intrusion of the greenstones in the graywackes was the cause of much stressing.

The metalliferous veins which occur in the diabase and sometimes also in the sandstone, are accompanied by fissures of calcite, and these again by barren fissures showing many slickensides. All of this indicates that movement has taken place.

Such relations between stratification, country rock, and metalliferous fissures give the entire complex an unusually varied character, so that the various forces to which it has been subjected have produced unequal stresses in its heterogeneous members. This condition of unequal stressing is to be considered one of the causes of air-blasts.

At the Maria shaft there are two distinct conditions producing air-blasts:

1. On driving drifts and cross-cuts in the hard greenstone, a crackling sound is frequently noticed. This is attributable to the formation of small fissures and is a warning to the miner, because angular fragments of rock are often thrown off with loud explosions from the face

of the drift. Fortunately, these pieces are rarely large, but they are sometimes of sufficient size to cause painful wounds. The cause is probably to be sought in the pressure which the hanging and foot-walls exert in many places on the dike or vein formation. In most cases this pressure is produced at points where the vein changes its strike or dip (Fig. 1). A movement of the hanging or of the foot-wall, or of both simultaneously, may then readily bring about a compression of the vein-matter. Such movements, as well as irregularity of the fissuring, are common characteristics of the Pribram veins. In cases where the walls are under pressure and converge, so that the vein-filling takes the shape of a wedge, large and heavy blocks of ground may readily break loose (Fig. 2).

On abandoning work in ground subject to air-blasts, the phenomenon as a rule rapidly quiets down, but promptly begins again when work is resumed. In spite of the use of the best methods of stope-filling known, the conditions in this mine are gradually growing worse, as the stopes extend and as the pressure of the hanging wall is concentrated on continually dwindling pillars of rock, but even under these conditions, air-blasts occur only in hard vein matter or country rock. When the ground is soft or gougy, considerable falls of rock are apt to take place, but these must not be confounded with the sudden and unexpected air-blasts.

2. A much more dangerous situation is produced by another type of air-blast, which occurred for the first time at Pribram in 1897, when the thirty-second level south (1,109 m.) on the main fissure of the Adalbert vein was driven. This mishap cost the life of one of the men. On July 7 of that year the face of the drift was 37 m. south of the Maria shaft east cross-cut, at K (Fig. 4). The drift was 2.2 m. high by 1.5 m. wide, and on the hanging wall side was in a greenstone dike, which had gradually pinched as the drift advanced. On the foot-wall the face was in hard quartzitic sandstone, plainly stratified and with a flat dip (Fig. 3). Just after the two miners on shift had thrown back the broken rock and were preparing to drill, a piece of rock, weighing nearly 200 lb., broke loose from the foot-wall side of the drift near the roof, exploding at the same time into a number of angular pieces of various sizes with a detonation like that of a powder explosion. Some of the pieces struck one of the men, crushing his skull and causing other serious wounds. Since then work in this portion of the mine, both on the thirty-first level (1,059 m.) and on the thirty-second level (1,109 m.) has been uninterruptedly continued, the stope at present reaching 15 to 30 m. above the level. Layers of explosive sandstone have been encountered frequently on both walls of the drifts, but fortunately there have been no further casualties, on account of the precautions mentioned below. Sandstone often occurs in the levels and stopes, but as yet no explosive strata have been found above the depth of 1,000 metres and then always in the neighborhood of the intersection between the trough of the syncline and Adalbert fissure, and in the flat southeasterly slope of the syncline. Such air-blasts as the above have never yet been encountered in the numerous workings of the southerly, steeper slope of the syncline.

The pieces of rock which are thrown off with the explosion, bursting into numerous smooth-faced angular pieces, average as a rule half a cubic metre in size. Frequently, a heavy air-blast at a particular place is followed at irregular intervals by a series of minor outbreaks, so that the stope cannot be approached with safety for hours, sometimes even for days. The various beds of graywackes are not all equally dangerous. It is rather the hard, fine-grained silicious layers which act in this way, rather than the mild and clayey strata, and it would appear that sudden changes in the character and

structure of the strata are responsible for the occurrence of air-blasts.

All of these air-blasts occurred in the main Adalbert fissure, which as yet is the only vein opened up on the thirty-first and thirty-second levels.

Considering all of the circumstances, the conclusion appears justified that the cause of these explosions is not only the pressure of the superincumbent rock-mass, which is at right angles to the strata, but is due also to a stress parallel to the bedding planes and to the axis of the syncline. This view is supported by the fact that thin streaks or layers of calcite, filling clefts between the strata opened by end pressure, not infrequently accompany the bedding planes of the formation. Such streaks occur at a depth of 1,080 metres on the tenth slope of the Adalbert vein and on the thirty-second level, 110 m. north of the Maria shaft. This explanation is furthermore borne out by a marked slatiness of the country rock, cutting the stratification at an angle of 60 to 90°. Cases occur where the fissility of the rock is parallel to the main Adalbert vein, the bedding planes of the rock at the same time being nearly horizontal. When such ground is under high pressure, it tends to break up into an aggregation of flat slabs. These are the conditions which appear to favor the occurrence of the air-blasts, so that when they occur one or more of the above-mentioned flat slabs are likely to break loose and explode.

Such conditions of stress demand serious consideration in executing work with a view to the greatest possible safety of the miners. They necessitate immediate removal of any broken ground in the stopes, especially where the walls are suspected of being favorable to air-blasts. Such removal of rock and ore must be promptly followed up by the stope-filling, so that no open spaces are left except those absolutely necessary for handling the ore, for ladder-ways and for ventilation. It is, moreover, the custom to reduce as much as possible the number of stopes in simultaneous operation and to distribute them over as large an area as possible. This is disadvantageous, as such an arrangement prevents concentration of the workings. Work at such points is prosecuted during one shift only, so that the ground is not disturbed for at least 16 hours out of each 24. This is for the purpose of allowing the stresses in the rock to equalize themselves. Only experienced and intelligent workmen are employed, and these are not changed without urgent reason, as it takes some time for men to become familiar with the ground. When air-blasts are anticipated, shields are frequently used. These are made of planks firmly spiked together and are braced against the point of danger by means of stulls. Such precautions, together with others which have been employed from time to time, have enabled the management to meet the danger successfully.

AMALGAMATION OF SILVER SULPHIDE.—It appears that silver sulphide is decomposed in the course of stamp-mill amalgamation. Mr. Keijiro Nakamuri, chief metallurgist of the Besshi copper mine, in Japan, states that at the Sado gold mine, situated on one of the islands in the Sea of Japan, the precious metals occur as a natural alloy having the composition of 58 parts of gold to 42 parts of silver. Even the beach gold, derived from the erosion of the quartz veins, has the same composition, as tested by 500 samples. In the stamp-mill the bullion from the battery amalgam contains 1 part gold to 3 parts silver, and the ratio of silver increases until, after passing over an apron, a shaking copper table, and two Duncan pans, the amalgam contains twelve times as much silver as gold. He considers this due to the decomposition of the argentite in the ore in the course of its passage over the plates and in the pans. He confirmed this by experiments on artificially prepared silver sulphide.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

PROCESS OF BRIQUETING.—No. 836,897; Robert Schorr, San Francisco, California.

The process of making coal briquets consisting in, first, heating the pulverized coal; second, melting the organic binder separately therefrom; third, mixing both substances while hot; fourth, reducing the mixture to a granular, floury condition by continued mixing under an air-blast; and, fifth, supplying the same while floury and cool to the press to make briquets, substantially as described.

AERIAL TRAMWAY.—No. 836,995; George G. Schroeder, Washington, D. C., assignor to Industrial Motor Company, a Corporation of the District of Columbia.

A monorack-tramway comprising uprights having their upper ends split and expanded to form sockets, and a rail of substantially arrow form in cross-section having its body fitting in the split portions of said uprights.

AUTOMATIC LOAD-BRAKE.—No. 836,912; Matthias A. Beck, Milwaukee, Wisconsin.

In an automatic load-brake the combination of a shaft having two expanding heads mounted thereon, one of said heads being movable axially toward and from the other, an expansible friction-ring between said heads, a shell surrounding said ring and free to turn in one direction, and means for holding said shell against turning in the opposite direction, substantially as described.

HOPPER OR BIN.—No. 836,679; Ulysses A. Garred, Anaconda, Montana.

In a dumping apparatus, a series of hoppers for receiving the material to be dumped, a discharging-door for each

hopper, means for retaining said doors in a closed position, a rock-shaft disposed in proximity to the hoppers, and suit-

able independently controllable pivoted levers extending across the shaft for actuating the retaining means and releasing the doors, upon, or independently of any movement of the rock-shaft, substantially as set forth.

ROCK-DRILL.—No. 837,118; Joseph J. Rekar, San Francisco, California.

The combination in a drill, of a channel guide-plate and support therefor, a frame slidable in the guides of said plate, a drill-shank, means for reciprocating said shank within the guided frame, a rack carried by the supporting-plate, a pawl carried by the movable frame and means carried by the reciprocating drill-shank whereby the pawl is caused to engage the rack and advance the drill and frame, said means including a collar upon the drill-shank and a fulcrumed pawl-carrying lever with which the collar contacts.

ROCK-DRILL.—No. 836,846; William C. Whitcomb, Chicago, Illinois.

In a rock-drill, in combination, a supporting column, a sleeve mounted on the column, a trunnion carried by the sleeve, a drill-cradle having a hub fitting over the trunnion, a worm-gear formed on the hub, and a worm-shaft journaled on the sleeve and meshing with the worm-gear.

DRILLING MACHINE.—No. 833,189; Richard Wheeler, Novinger, Missouri.

In a drilling machine, the combination with a rotary threaded drill-bar, of a worm-wheel constituting a seat therefor, a supporting-shaft for the worm-wheel, a bracket upon the shaft, driving mechanism including meshed gears upon the bracket and the drill-bar, a friction element having a threaded connection with the shaft for adjustment toward and away from the worm-wheel, and provided in one face with an annular series of sockets, and a locking-pin carried by the bracket and capable of engagement with any of the sockets to adjustably lock the friction element.

New Uses for Asbestos.

The present wide development of the asbestos manufacturing industry has produced various products, the basis of which is asbestos, and adapting them for use in building construction. Asbestos is a natural heat insulator. Its silky fibres are capable of manipulation into any form. They are not affected by the extreme weather conditions, and are absolutely fire-proof and of moderate cost. Commencing at the very foundation of modern buildings, asbestos and its by-products enter largely into their construction, and it is used throughout, exterior and interior, even to roof coverings. The H. W. Johns-Manville Co. has developed various lines of building materials, the basis of which is asbestos. After the first-floor joists of a modern residence are put in place, asbestic plaster can be used in conjunction with either wood or metal lathing as a 'scratch' coat on the ceiling of the cellar. Thus used, it offers a positive fire barrier between floors, and presents the most satisfactory form of plastering known.

Between all floors, and between the outside boarding and clapboards, the use of asbestos sheathing papers and sheathing quilts has met with universal success. These have many advantages over other products, owing to their natural fire resisting properties. They not only prevent the transmission of sound waves between rooms, but will effect a saving in fuel of large proportions, when placed upon the side walls of wooden structures. Similar felts are also used on roofs, under shingles and slates, and insure a comfortable building throughout the entire year.

The Giroux Hot-Blast Top.

The National Metallurgical Co., of Matehuala, is almost ready to put into service the new blast-furnace designed by the Traylor Engineering Co. This furnace measures 42 by 160 in. at the tuyeres, and will treat 250 to 300 tons per day. The furnace is fitted with the Giroux hot-blast top, which consists mechanically of two series of metal pipes arranged symmetrically around the inside of the top of the furnace, the lower ends of the pipes being just above the top of the charging floor. The vertical portion of the pipes is built of sheet steel. These are circular at the bottom where they join the return elbows, and oval and of larger section at the top. The material of the pipes makes them readily permeable to the heat, and their form gives them a large surface for absorbing the heat from the furnace gases. Their form also prevents dust from adhering to them and reducing their capacity for absorbing heat. Near their tops the pipes are connected together in pairs sidewise by means of flanged cast-iron connections, and at the bottoms each pair of pipes is connected to form a continuous series on each side of the furnace by means of cast-iron return elbows. These elbows have a V-shaped section, with one side of the V lying parallel with the side of the furnace top, and the other forming a slope for the hot-furnace gases to impinge against. The cast-iron is used for the elbows because it is the best material to resist the destructive action of the impinging furnace gases. The form of the elbows insures the delivery of the hot gases and its distribution along the sides of the upright pipes in the best manner to insure their giving up of their heat to the blast air passing through the pipes. The attachment is built so that it may be used on furnaces with either sheet metal or brick tops, but the use of the brick top is always recommended. The brick is best because it is a good non-conductor of heat, and thus concentrates the heat of the furnace in the air-pipes.

The blast from the blower enters the furnace at the top of the attachment at the two ends. It then circulates through the air-heating pipes in series after traversing their length passes down through the hot-air connection into the bustle pipe of the furnace, and from thence through the blow-pipes to the tuyeres. This top is mechanically perfect. There is no distortion produced by the heat, as all of the heating pipes are entirely surrounded by the furnace gases, and the expansion is therefore uniform throughout their length. This prevents the distortion from heat which has made other arrangements intended for this purpose failures.

This system has been in use for three years at the United

Verde smelter and has proved a great source of fuel economy, besides showing that the design is entirely successful in resisting the destructive effects of contraction and expansion which have made other designs too expensive to maintain. This top, which is also in use at the Giroux Consolidated Mines Co., at Ely, costs practically nothing for repairs. Experience has shown that this system, producing a blast of 400° F., effects a saving of 30% of the fuel charge with some ores, while at the same time increasing the capacity of the furnace 15 to 25%. It allows the use of charges containing 2 to 4% more silica, and the more uniform temperature seems to prevent to some extent the crusting and building up of the walls of the furnace, so noticeable in ordinary practice. The Giroux hot-blast top is applied with advantage and economy to copper-smelting furnaces, where the process is largely oxidizing, and as a result the zone of heat is carried to a comparatively high one in the furnace. The heat thus produced is utilized in heating the blast instead of being wasted.

Publications Received.

NICKEL STEEL. By Albert Ladd Colby. A reprint from the Proceedings of the American Society for Testing Materials. Distributed by the Orford Copper Co., New York.

UNITED STATES GEOLOGICAL SURVEY.—1. 'Ore Deposits of the Silver Peak Quadrangle, Nevada,' by J. E. Spurr. A valuable monograph of 175 pages. 2. 'Geology of the Bighorn Mountains,' by N. H. Darton. A similar report, of 130 pages. 3. 'Geology and Mineral Resources of Mississippi,' by A. F. Crider. A bulletin of 95 pages. 4. 'Report on Progress of Investigations of Mineral Resources of Alaska in 1905,' by A. H. Brooks and others; 165 pages. Contains several valuable descriptive articles. 5. 'Bibliography and Index of North American Geology, Paleontology, Petrology, and Mineralogy,' for the years 1901-1905, inclusive, by F. B. Weeks; 740 pages. An extremely useful book of reference. 6. 'Contributions to Economic Geology,' 1905, edited by S. F. Emmons and E. C. Eckel. A bulletin of 500 pages. Not as rich in material as preceding volumes of this series but it contains much valuable information.

Trade Treatises.

T. H. PROSKE, of Denver, issues an illustrated catalogue of the Ajax Drill Sharpener. The pamphlet includes numerous testimonials as to the efficiency of the machine.

THE UNITED IRON WORKS CO., of Springfield, Mo., issues a neat catalogue describing the concentrating machinery that it manufactures. Several drawings of mills are included.

THE AMERICAN DIAMOND ROCK DRILL CO. has issued catalogue No. 26, entitled 'The Diamond Drill and Its Work.' The catalogue contains 88 pages, and besides thoroughly describing the diamond-core drills manufactured by the company, gives many records of performances that should be read with interest by engineers and contractors. There is also a brief description of the kinds of diamonds used and the process of mining and preparing them. The pamphlet closes with complete tables of prices, shipping weights, and duplicate parts.

Commercial Paragraphs.

ALLIS-CHALMERS CO., of Milwaukee, issues Bulletin No. 1,510, describing their direct-connected Reynolds Corliss Engines. The bulletin is well illustrated.

THE COLORADO IRON WORKS CO., of Denver, issues Bulletin No. 22, which is devoted to Crushing Rolls, a form of mining machinery for which this company has won a high reputation.

THE SAMSON MANUFACTURING CO., of Denver, Colo., recently received orders for one No. 3 Samson Crusher for shipment to the Wind River M. Co. at Shoshone, Wyoming (this was sold by the Merralls Mill Co.), two No. 4 Crushers to Fairbanks, Morse & Co., one for shipment to Salt Lake City, and the other for the Denver branch, and one No. 4 to the Colorado Iron Works Company.
